The Journal

OF THE

American Medical Association

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES BY

AUSTIN SMITH, M.D.

VOLUME 165 September-December, 1957

AMERICAN MEDICAL ASSOCIATION, CHICAGO 10

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION—1957-1958

Headquarters of the Association, 535 N. Dearborn St., Chicago 10

President, DAVID B. ALLMAN - - - - - - - - - Atlantic City, N. J.
President-Elect, GUNNAR GUNDERSEN - - - - - - - La Crosse, Wis.
Vice President, JESSE D. HAMER - - - - - - - - - Phoenix, Ariz.
Secretary and General Manager, GEORGE F. LULL - - - - - Chicago
Treasurer, J. J. MOORE - - - - - - - - - - - - - Chicago
Speaker, House of Delegates, E. VINCENT ASKEY - - - - Los Angeles
Vice Speaker, House of Delegates, LOUIS M. ORR - - - Orlando, Fla.
Editor, AUSTIN SMITH - - - - - - - - - - - - - - Chicago

BOARD OF TRUSTEES

E. S. HAMILTON, *Chairman*, Kankakee, Ill., 1958; R. M. MCKEOWN, Coos Bay, Ore., 1958; H. H. HUSSEY, Washington, D. C., 1959; F. J. L. BLASINGAME, Wharton, Texas, 1959; L. W. LARSON, Bismarck, N. D., 1960; J. Z. APPEL, Lancaster, Pa., 1960; J. P. PRICE, Florence, S. C., 1961; G. M. FISTER, Ogden, Utah, 1962; C. A. NAFE, Indianapolis, Ind., 1962; the President and the President-Elect; and, ex officio, the Vice President, Treasurer, Speaker and Vice Speaker of the House of Delegates.

Assistant Secretary, ERNEST B. HOWARD - - - - - - - - - Chicago

Business Manager, MR. THOMAS R. GARDINER - - - - - - - Chicago

JUDICIAL COUNCIL

G. A. Woodhouse	Pleasant Hill, Ohio,	1958
J. M. Hutcheson	Richmond, Va.,	1959
L. A. Buie	Rochester, Minn.,	1960
R. Ward	San Francisco,	1961
H. L. Pearson Jr., *Chairman*	Miami, Fla.,	1962
G. F. Lull, *Secretary*	Chicago	

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

V. Johnson	*Rochester, Minn.,*	*1958*
L. S. McKittrick, Chairman	Brookline, Mass.,	1958
C. T. Stone Sr.	Galveston, Texas,	1959
W. A. Bunten	Cheyenne, Wyo.,	1959
J. M. Faulkner	Cambridge, Mass.,	1960
H. English	Danville, Ill.,	1960
G. A. Caldwell	New Orleans,	1961
J. W. Cline	San Francisco,	1961
W. C. Wescoe	Kansas City, Kan.,	1962
Warde B. Allan	Baltimore,	1962
E. L. Turner, *Secretary*	Chicago	

COUNCIL ON MEDICAL SERVICE

R. B. Chrisman Jr.	Coral Gables, Fla.,	1958
J. F. Burton	Oklahoma City,	1958
J. D. McCarthy, Chairman	Omaha,	1959
J. Lafe Ludwig	Los Angeles,	1959
H. B. Mulholland	*Charlottesville, Va.,*	*1960*
H. B. Woolley	Idaho Falls,	1960
C. E. Wertz	Buffalo,	1961
T. J. *Danaher*	*Torrington, Conn.,*	*1961*
R. L. Novy	Detroit,	1962
D. H. Murray	Napa, Calif.	
Mr. George W. Cooley, *Acting Secretary*	Chicago	

COUNCIL ON CONSTITUTION AND BYLAWS

S. H. Osborn	Hartford, Conn.,	1958
F. S. Winslow	Rochester, N. Y.,	1959
B. E. Pickett Sr., Chairman	*Carrizo Springs, Texas,*	1960
Walter E. Vest	Huntington, W. Va.,	1961
W. W. Furey	Chicago,	1962
avid B. Allman	*Atlantic City, N. J.*	
. V. Askey	Los Angeles	
. M. Orr	Orlando, Fla.	
J. Z. Appel	Lancaster, Pa.	
Mr. George Hall, *Secretary*	Chicago	

COUNCIL ON DRUGS

(Standing Committee of Board of Trustees)

T. Sollmann, Chairman	Cleveland,	1957
J. P. Leake	Washington, D. C.,	1957
A. C. Curtis	*Ann Arbor, Mich.,*	1957
W. C. Cutting	San Francisco,	1958
O. O. Meyer	Madison, Wis.,	1958
M. H. Seevers	Ann Arbor, Mich.,	1958

F. A. Humphrey	Ft. Collins, Colo.,	*1960*
N. H. Gardner	E. Hampton, Conn.,	1960
A. T. Stewart	Lubbock, Texas,	*1961*
C. B. Andrews	Sonoma, Calif.,	1961
Mrs. A. Hibbard, Secretary	Chicago	

COUNCIL ON MENTAL HEALTH

(Standing Committee of Board of Trustees)

M. R. Kaufman	New York,	1957
L. H. Bartemeier, Chairman	Baltimore,	1958
W. H. Baer	Peoria, Ill.,	1958
H. F. Ford	Galveston, Texas,	1958
L. H. Smith	Philadelphia,	1959
G. E. Gardner	Boston,	1959
F. M. Forster	Washington, D. C.,	1960
H. T. Carmichael	Chicago,	*1961*
R. J. Plunkett, Secretary	Chicago	

The Secretary, Assistant *Secretary and Editor are ex officio members of all Standing Committees*

SECTION OFFICERS 1957-1958

Anesthesiology—Chairman, K. C. McCarthy, Toledo, Ohio; Secretary, *Daniel C. Moore, 1118 Ninth Ave., Seattle 1.*

Dermatology—Chairman, Earl D. Osborne, Buffalo, N. Y.; Secretary, C. S. Livingood, 2799 W. Grand Blvd., Detroit 2.

Diseases of the Chest—Chairman, John F. Briggs, Saint Paul, Minn.; Secretary, Burgess L. Gordon, 1810 Rittenhouse Sq., Philadelphia 3

Experimental Medicine and Therapeutics—Chairman, George Burch, New Orleans; Secretary, Elliot V. Newman, Vanderbilt University Hospital, *Nashville* 5, Tenn.

Gastroenterology and Proctology—Chairman, Everett D. Kiefer, Boston; Secretary, William H. Dearing, 200 First St., S.W., Rochester, Minn.

General Practice—Chairman, Charles E. McArthur, Olympia, Wash.; Secretary, Eugene I. Baumgartner, 25 Alder St., Oakland, Md.

Internal Medicine—Chairman, Albert M. Snell, *Palo Alto, Calif.*; Secretary, Rudolph H. Kampmeier, *Vanderbilt University Hospital, Nashville* 5, Tenn.

Laryngology, Otology, and Rhinology—Chairman, Alden Miller, Los Angeles; Secretary, Hugh A. Kuhn, 112 Rimbach St., Hammond, Ind.

Military Medicine—Chairman, Maj. Gen. Silas B. Hays, Washington, D. C.; Secretary, Col. Charles Bramlitt, Directorate of Professional Services, AFCSG-10, Office of the Surgeon General, USAF, 3800 Newark St., N.W., Washington 25, D. C.

Nervous and Mental Diseases—Chairman, Harold C. Voris, Chicago; Secretary, Adolph L. Sahs, University Hospitals, Iowa City, Iowa.

Obstetrics and Gynecology—Chairman, Woodward B. Beacham, *New* Orleans; Secretary, Keith P. Russell, 511 S. Bonnie Brae St., Los Angeles.

Ophthalmology—Chairman, Dohrmann K. Pischel, San Francisco; Secretary, Harold G. Scheie, 313 S. 17th St., Philadelphia.

Orthopedic Surgery—Chairman, Frederick R. Thompson, New York; Secretary, H. Herman Young, 200 First St., S.W., Rochester, Minn.

Pathology and Physiology—Chairman, Edwin F. Hirsch, Chicago; Secretary, Hugh A. Edmondson, 1200 N. State St., Los Angeles 33.

Pediatrics—Chairman, George M. Wheatley, New York; Secretary, Wyman C. C. Cole, 3011 W. Grand Blvd., Detroit.

Physical Medicine—Chairman, Miland E. Knapp, Minneapolis; Secretary, Earl C. Elkins, 200 First St., S.W., Rochester, Minn.

Preventive Medicine—Chairman, Bruce Underwood, Washington, D. C.; Secretary, Frank Princi, University of Cincinnati College of Medicine, Cincinnati 19.

Radiology—Chairman, Wendell G. Scott, St. Louis; Secretary, Traian Leucutia, Harper Hospital, Detroit 1.

Surgery, General and Abdominal—Chairman, Frank L. Gerbode, San *Francisco; Secretary, Gustaf* E. Lindskog, 333 Cedar St., New Haven 11, Conn.

Urology—Chairman, Roger W. Barnes, Los Angeles; Secretary, Thomas A. Morrissey, 40 E. 61st St., New York 21.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, SEPTEMBER-DECEMBER 1957

Abstracts have been made of important articles in the following journals in the Current Medical Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by the Library of the American Medical Association to individuals in Continental United States and Canada who subscribe to its scientific periodicals and to members of the American Medical Association and its student organization. No charge is made to members, but the fee for other borrowers is 15 cents in stamps for each periodical. Three journals may be borrowed at a time for a period not exceeding five days. Thus most of these journals are accessible to the general practitioner.

'LANOXIN'®
brand
DIGOXIN

formerly known as Digoxin 'B.W. & Co.'®

"If one digitalis agent were to be recommended for its adaptability to the many and varied clinical contingencies, we believe Digoxin would be [a] drug of choice."

Lown, B., and Levine, S. A.:
Current Concepts in Digitalis Therapy, Boston,
Little, Brown & Company, 1954, p. 23, par. 2.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

the full committee a new bill on the registration of welfare and pension plans, most of which involve health insurance.

The measure will lay over until January, when the full committee will take it up.

The draft legislation somewhat resembles an earlier bill sponsored by three committee members, Senators Douglas, Murray, and Ives. A major change would place administration of the proposed law in the hands of the Secretary of Labor instead of the Securities and Exchange Commission. The subcommittee, headed by Senator Kennedy, heard conflicting testimony on this subject.

The bill provides for compulsory registration and reporting to the Secretary of all types of plans whether run by management or unions. The reports would be available to the public, and beneficiaries of plans would be entitled on request to receive summaries of the reports from the operators of the plans. Financial reports would have to be based on certified units.

A policy statement in the bill notes a "rapid and substantial growth" of employee welfare and pension funds and says that they have become an important factor affecting the stability of employment as well as the continued well-being and security of millions of employees and their dependents.

Accordingly, it is desirable "in the interests of employees and their beneficiaries for the protection of the revenue of the United States and to provide for the general welfare and the free flow of commerce, that disclosure be made with respect to the operation and administration of such plans."

Both this committee and a House Education and Labor Committee have uncovered a number of abuses in the conduct of such plans.

BIOLOGICAL EFFECTS OF RADIATION STILL IN DISPUTE

The country's foremost authorities on the biological effects of radiation still are far from agreement on (*a*) the dangers to which man already has been exposed and (*b*) what continued testing of weapons will produce in man.

Summarizing testimony presented in eight days of hearings, the Joint Committee on Atomic Energy says:

"There was general agreement [among witnesses] that any amount of radiation, no matter how small the dose, increases the rate of genetic mutation in a population. There was, on the other hand, a difference of opinion as to whether a very small dose of radiation would produce similarly an increased incidence of such somatic [nongenetic] conditions as leukemia or bone cancer, or a decrease in life expectancy, in a population. . . .

"There were differences of opinion on how to forecast the consequences of further testing. The differences hardest to reconcile appear to be those concerning the biological effects of radiation.

"Pending a resolution of differences, it would appear from the information presented that the consequences of further testing over the next several generations at the level of testing of the past five years could constitute a hazard to the world's population. It is very difficult, if not impossible, to forecast with any real precision the number of people that would be affected."

The report describes how strontium from fall-out reaches man through vegetables that have become contaminated, through milk from contaminated cows, and through other sources. It summarizes the effect of strontium as follows, a conclusion apparently agreed to by the witnesses:

"Strontium participates in biological processes resulting in eventual deposition in the human body, almost entirely in bone.

"Strontium stays in the bones a long time and has a 28-year half-life; that is, the beta rays emitted by strontium 90 and its daughter element yttrium 90 irradiate the bone over a long period of time. But strontium 90, concentrating in the bones and emitting beta radiation, is primarily a somatic not a genetic hazard."

JOINT BLOOD COUNCIL LAUNCHES NEW SURVEY OF TRANSFUSION SERVICES

A second and more extensive mail questionnaire is being distributed to more than 5,200 hospitals, blood banks, and other blood transfusion services by the Joint Blood Council. The council and its sponsoring organizations are seeking to coordinate the country's blood banking facilities, practices, and terminology.

The first survey, conducted last year, provided the first reliable estimate in six years of how much blood is being transfused in the United States. The council said that the survey also showed that blood transfusion services are operating under handicaps that need remedy. The latest survey is designed to provide data to bring about the remedies. The council cites, for example, the fact there is no precise definition of the term "unit" of blood; in some instances, a unit is 480 cc. and in others, 250 cc.

The new survey includes these questions: Are blood transfusion services capable of rapid expansion in time of emergency? Where are they located? How are they organized and operated? What areas do they serve? What is their annual volume of business? How do they relate to allied services such as tissue banks?

Federal agencies concerned with hospitals, as well as pharmaceutical and hospital supply firms, are expected to derive benefit from the data collected, the council points out.

Organizations sponsoring the council are the American Medical Association, American Hospital Association, American Association of Blood Banks, American Red Cross, and the American Association of Clinical Pathologists.

VA DEVELOPS INSTRUMENT TO MEASURE RADIOACTIVE PARTICLES IN BODY

An instrument so sensitive that it can measure the small amounts of radioactivity naturally present in the human body has been developed by the Veterans Administration. The device, titled a total body radioactivity counter, was designed and developed by Dr. Gerald J. Hine of the VA Hospital in Boston.

The counter will be used to study some functions by tracing activity of natural radioactivity of the body and also to chart the course of radioisotopes introduced into the body. Because only small amounts of radioactivity would have to be put in the body, the new counter will have the advantage of making possible longer study of the patient than was possible before, according to the VA.

THE PROBLEM OF FEVER IN PATIENTS WITH VALVULAR HEART DISEASE

Richard S. Ross, M.D., Victor A. McKusick, M.D.
and
John C. Harvey, M.D., Baltimore

The clinical situation in which fever and valvular heart disease coexist presents a problem in differential diagnosis and management which is quite different from that associated with either condition alone. The causes of fever more or less peculiar to valvular heart disease are active rheumatic fever, bacterial endocarditis, drug fever, embolism, congestive heart failure, hemoglobin pneumonia, systemic lupus erythematosus, and atrial myxoma or thrombus. Bacterial endocarditis should be given first consideration when fever and heart murmur coexist.

THE proper interpretation of fever in patients with valvular heart disease can be one of the most perplexing problems confronting the internist. The clinical situation in which fever and valvular heart disease coexist presents a problem in differential diagnosis and management which is quite different from that associated with either condition alone. In a patient with fever and valvular heart disease, the physician must, of course, consider all the usual causes of fever. Individuals with heart murmurs have at least the usual susceptibility to the infectious, neoplastic, and other diseases which produce fever. It is with the group of diseases which causes fever more or less peculiar to valvular heart disease that we are primarily concerned.

We have been impressed with the relatively high frequency with which this problem arises in general hospital practice. No attempt has been made to review all the patients presenting this problem in the Johns Hopkins Hospital. Therefore, no statistical analysis of the final diagnoses or of the incidence of the condition is justified. However, 25 patients who posed this problem in striking form were observed by us during the years 1951 to 1954 when we were resident physicians of the Osler Medical Service. The conclusions reached are based on a review of these 25 cases listed in the table. The cases of three patients are described in detail in this paper (cases 1, 2, and 14).

The causes of fever more or less peculiar to valvular heart disease are as follows: 1. Active rheumatic fever (cases 1 through 10). 2. Postcommissurotomy syndrome (cases 11 and 12). 3. Bacterial endocarditis (cases 13 and 14). 4. Drug fever. 5. Embolism (cases 15 through 19). 6. Miscellaneous. Under this grouping are included congestive heart failure, hemoglobin pneumonia (cases 20 and 21), systemic lupus erythematosus (case 22), and atrial myxoma or thrombus (cases 23 through 25).

We have not attempted to give a comprehensive discussion of each disease. The discussion is oriented about the problem of the patient with fever and a heart murmur, and the various diseases are mentioned only as they enter into the consideration of such a patient.

Active Rheumatic Fever or Subacute Bacterial Endocarditis

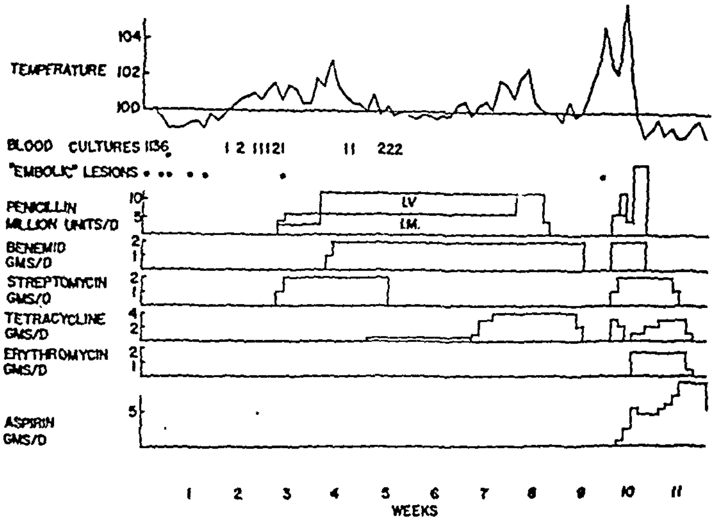
In both cases 1 and 2 the major diagnostic possibilities were active rheumatic fever and bacterial endocarditis.

From the Department of Medicine, the Johns Hopkins University and Hospital.

CASE 1.—A 27-year-old male schoolteacher gave no definite history of acute rheumatic fever, but exertional dyspnea and a heart murmur had been present since he was 12 years of age. The patient reported several illnesses characterized by episodes of fever and dyspnea, described as "pneumonia." Four months prior to the final hospital admission he complained of increasing exertional dyspnea, cough, orthopnea, and paroxysmal nocturnal dyspnea. There were several episodes of malaise, drenching night sweats, and temperature to 103 F (39.44 C); each of these episodes subsided with penicillin therapy. Three weeks prior to admission, painful swelling of the upper part of the abdomen was noted. For the first time the patient complained of swelling and stiffness of the ankles, knees, and knuckles. The joint symptoms persisted only a few days, but malaise, fever, and symptoms of increasing cardiac decompensation continued.

The patient was pale and chronically ill. Two typical splinter hemorrhages were seen beneath the nails of the second and fourth fingers of the right hand. There were a few fresh petechiae on the right side of the soft palate. There was no evidence of joint disease. There was generalized lymph node enlargement. The heart was enlarged. There were signs of mitral stenosis and atrial fibrillation. The liver was large and tender, but the spleen was not felt.

The patient's hospital course is illustrated in the figure. During the first two weeks the peripheral leukocyte count remained below 10,000 per cubic millimeter; the sedimentation rate (Wintrobe-Landsberg method) was 30-40 mm. per hour; the hematocrit reading was normal. The urine contained neither albumin nor red blood cells.



Clinical course of patient in case 1.

Vigorous therapy was directed at the failing heart with essentially no effect. The patient remained afebrile, but new "embolic" lesions continued to appear. The splinter hemorrhages seen on admission disappeared, and new ones developed. In the mucous membranes, petechiae appeared and disappeared. Bacterial endocarditis was suspected because of the history of fever and the petechial lesions. Twenty blood cultures were obtained during this period of observation, and Streptococcus faecalis grew from one. In view of the positive culture and the numerous lesions, interpreted as embolic, it was decided to treat the patient for bacterial endocarditis.

During the third week he was started on therapy with 6 million units of penicillin and 2 Gm. of streptomycin-dihydrostreptomycin a day. During the first week of antibiotic administration, he showed no improvement, his fever increased, and, because of this apparent lack of response, tetracycline was also given. After five weeks, the penicillin and streptomycin were withdrawn, but tetracycline therapy was continued. For five days the patient remained afebrile, but then the fever recurred, with the temperature reaching 105 F (40.56 C) eight days after withdrawal of the antibiotics. New petechiae appeared; the patient complained of dyspnea and cough; and the leukocyte count rose to 20,000 per cubic millimeter. The hematocrit reading at that time was 43%.

The physicians managing the case felt obligated to reinstitute antibiotic therapy, and this was done at the end of the 10th week, with 6 million units of penicillin, 2 Gm. of probenecid (Benemid), 2 Gm. of tetracycline, and 1.6 Gm. of erythromycin being given daily. Blood cultures taken during the febrile period between courses of therapy were sterile. The temperature continued to rise in spite of the antibiotics, reaching 106 F (41.11 C) at the end of the 10th week. Throughout the hospital course, heart failure was a major problem. The patient's chief and often only complaint was dyspnea. It had been difficult to control the ventricular rate with 0.2 mg. of digitoxin a day, and the pulse deficit increased with the rising temperature. The patient required oxygen almost constantly. At the beginning of the 11th hospital week, aspirin in a dosage of 5-6 Gm. a day was given. With this regimen the temperature remained normal more consistently than at any time in previous weeks. The ventricular rate fell to 70 per minute. The patient remained afebrile for the next 11 days but continued to complain of dyspnea. During the 12th hospital week he developed acute pulmonary edema and died.

At postmortem examination, lesions of acute and chronic rheumatic fever were seen in the myocardium, endocardium, valves, and pulmonary artery. There were small organized thrombi in the lungs and liver. There was absolutely no evidence of active or healed bacterial endocarditis.

CASE 2.—At 13 years of age the patient in case 2 experienced an initial episode of painful swelling of the knees and ankles. She was first admitted to the hospital when she was 17 years old because of fever and increasing dyspnea after dental extractions. Physical examination revealed fever, the auscultatory signs of mitral stenosis, atrial fibrillation, and pulmonary congestion. The peripheral leukocyte count was 18,000 per cubic millimeter, and the sedimentation rate was 38 mm. per hour. The patient was treated with 2.4 Gm. of aspirin a day; with this treatment she became afebrile and improved symptomatically. She was discharged on maintenance therapy with aspirin and prophylactic sulfadiazine.

Nine weeks after discharge she was readmitted with fever, joint pains, and a rash. The fever and joint pains responded promptly to aspirin and bed rest. However, after two weeks of improvement the temperature rose to 101-102 F (38.33-38.89 C) and could not be controlled with aspirin in doses of 4.8 Gm. daily. The appearance of cutaneous petechiae aroused suspicion of bacterial endocarditis. Thrombosis of the right innominate vein developed, and because of this complication heparin sodium therapy was instituted. With great suddenness petechiae appeared on the soft palate, arms, and chest. The prothrombin time was found to be 50 seconds (prothrombin concentration was less than 25% of normal) on the day the petechial lesions appeared. No bishydroxycoumarin (Dicumarol) had been given, but it was felt that the combination of hepatic congestion and aspirin could well account for the prolonged prothrombin time. Vitamin K was given, with prompt return of the prothrombin time to 29 seconds (prothrombin concentration was 40% of normal). Petechiae continued to appear on the palate and the extremities. Repeated blood cultures were sterile. The temperature remained between 101 and 103 F (38.33 and 39.44 C). There was great difficulty controlling the heart rate with digitalis, and signs of cardiac failure increased. Because of the continuing fever, petechiae, and venous thrombosis, it was decided to treat the patient for bacterial endocarditis. Fifteen million units of penicillin was administered daily for three weeks, with a slow but definite response in the amount of fever. The response was of short duration.

During treatment with penicillin the patient developed tenderness at injection sites, and it was felt that chemical myositis might be contributing to her fever. After a week's observation of the patient while she was on therapy with penicillin, it was clear that her condition was worsening and the drug was withdrawn. The temperature dropped to normal as the myositis subsided The patient developed massive swelling of the face and neck, presumably secondary to thrombosis of the major venous channels Fever returned, and the patient died during the eighth week of hospitalization

Rheumatic myocarditis with Aschoff bodies was found at autopsy. There was rheumatic endocarditis but no evidence of bacterial vegetations There were thrombi in the atria, and multiple, remote and recent, pulmonary emboli were noted. There were multiple venous thromboses involving jugular and axillary veins

In both of these cases the incorrect diagnosis of bacterial endocarditis was made and treatment given. This diagnostic error cannot be criticized Bacterial endocarditis should be a prime consideration in a patient with rheumatic heart disease and fever. It is usually curable with proper treatment and is almost invariably fatal if treatment is withheld.

The diagnosis of endocarditis is confirmed by the demonstration of bacteremia, therefore, adequate blood cultures must be obtained as the first step in the investigation of fever in patients with valvular heart disease. There is a great deal of information in the literature concerning the number of cultures that may be considered adequate, the duration of the

Review of Twenty-five Cases of Valvular Heart Disease with Fever

Case No	Sex	Age, Yr	Heart Disease	Temperature, F (C)	Complicating Features	Cause of Fever	Remarks
1	M	27	Rheumatic heart disease, mitral stenosis, atrial fibrillation	101 103 (38 33 39 44)	Petechiae, splinter hemorrhages	Active rheumatic myocarditis (autopsy)	See text
2	F	17	Rheumatic heart disease, mitral stenosis, atrial fibrillation	101 103 (38 33 39 44)	Petechiae, venous thromboses penicillin myositis	Active rheumatic myocarditis (autopsy)	See text
3	F	30	Rheumatic heart disease mitral regurgitation	100-101 (37 78-38 33)		Active rheumatic fever (course)	Defervescence with hydroxy phenyl cinchoninic acid
4	F	36	Rheumatic heart disease, mitral stenosis	Low grade, intermittent	Hematuria pulmonary infarction, splinter hemorrhages	Active rheumatic endocarditis with multiple emboli (course)	All studies for bacterial endocarditis negative
5	F	35	Rheumatic heart disease, mitral regurgitation, aortic regurgitation	100-101 (37 78-38 33)	Intractable heart failure	Acute and chronic rheumatic myocarditis (autopsy)	
6	F	27	Rheumatic heart disease, mitral stenosis, aortic regurgitation, atrial fibrillation	100-101 (37 78-38 33)	Anemia, Roth s spots in fundus, night sweats	Rheumatic myocarditis (autopsy)	Dental extraction preceding admission
7	M	45	Rheumatic heart disease, mitral stenosis, mitral regurgitation, aortic regurgitation	101 102 (38 33 38 89)	Hematuria, myalgia, splenomegaly	Active rheumatic fever (course)	
8	F	30	Rheumatic heart disease, mitral stenosis	103 (39 44)	Heart failure	Active rheumatic myocarditis (course)	Activation of rheumatic fever after cardiac catheterization
9	M	19	Rheumatic heart disease, mitral stenosis, mitral regurgitation, aortic regurgitation	100-101 (37 78-38 33)	Heart failure, splenomegaly, digital clubbing, hematuria	Active rheumatic myocarditis (autopsy)	Perionychial erythema also striking
10	F	36	Rheumatic heart disease, mitral stenosis	100-101 (37 78-38 33)	Heart failure, splinter hemorrhages	Re stenosis of mitral valve after commissurotomy (autopsy)	No definite histological evidence of rheumatic activity, but re-stenosis of valve 4 yr after operation taken as evidence of rheumatic activity One blood culture positive for Streptococcus faecalis
11	M	24	Rheumatic heart disease, mitral stenosis	101 104 (38 33-40 00)	Petechiae, tender, swollen fingertips	Active rheumatic myocarditis (course)	"Postcommissurotomy *syndrome*"
12	F	36	Rheumatic heart disease, mitral stenosis	101 103 (38 33-39 44)	Pleural effusion, heart failure	Active rheumatic myocarditis (course)	[illegible]
13	M	34	Aortic regurgitation, rheumatic heart disease (?), syphilis ( )	100-103 (37 78-39 44)	Heart failure	Bacterial endocarditis (autopsy), syphilitic aortitis	20 blood cultures negative
14	M	18	Rheumatic heart disease, mitral regurgitation	98-102 (36 67-38 89)	Heart failure, pericarditis	Bacterial endocarditis, coronary embolism (autopsy)	Temperature fell with hydroxy phenyl cinchoninic acid, see text
15	F	39	Rheumatic heart disease, mitral stenosis, aortic regurgitation	100-103 (37 78-39 44)	Heart failure, splenomegaly, pulmonary infarction	Pulmonary and coronary embolism (autopsy)	Clinical impression rheumatic myocarditis
16	F	41	Rheumatic heart disease, mitral stenosis, mitral regurgitation	100-102 (37 78-38 39)	Heart failure, atrial fibrillation	Subacute and chronic rheumatic endocarditis and myocarditis, splenic and cerebral embolism (autopsy)	
17	F	34	Rheumatic heart disease, mitral stenosis, aortic regurgitation	101 104 (38 33-40 00)	Pleural effusion, heart failure	Pulmonary and splenic embolism (autopsy)	
18	M	49	Rheumatic heart disease, aortic regurgitation, aortic stenosis	100-101 (37 78-38 33)	Petechiae, splinter hemorrhages, splenic infarction	Sterile embolization, 16 blood cultures negative (course)	Endocarditis treated 4 mo previously
19	F	27	Rheumatic heart disease, mitral regurgitation	99 100 (37 22 37 78)	Splinter hemorrhages	Sterile embolization, 7 blood cultures negative (course)	Endocarditis treated 3 mo previously
20	M	28	Rheumatic heart disease, mitral stenosis	99 (37 22)	Hemoptysis, night sweats	Chronic passive congestion of lungs, recent and organized pulmonary hemorrhage (autopsy)	Tuberculosis considered clinically
21	M	39	Rheumatic heart disease, mitral stenosis	103 (39 44)	Hemoptysis, night sweats	Hemoglobin pneumonitis (course)	381 million units penicillin for subacute bacterial endocarditis
22	M	44	Mitral stenosis	100-103 (37 78-39 44)	Hematuria, clubbed fingers, pericarditis, splenomegaly	Systemic lupus erythematosus (autopsy)	
23	F	58	Rheumatic heart disease, mitral stenosis, mitral regurgitation, (antemortem diagnosis)	100-102 (37 78-38 89)	Fever, weight loss, pulmonary and systemic embolism	Myxoma of left atrium, embolization of pulmonary and systemic circulations (autopsy)	
24	F	37	Rheumatic heart disease, mitral stenosis, mitral regurgitation	101 (38 33)	Syncopal attacks	"Ball valve" thrombus, left atrium (autopsy)	
25	F	33	Rheumatic heart disease, mitral stenosis, mitral regurgitation, (antemortem diagnosis)	101 103 (38 33-39 44)	Systemic embolism	Myxoma, left atrium	Long treatment for subacute bacterial endocarditis

culturing period, and ideal bacteriological techniques.[1] These factors should be considered before it is stated that bacteremia is not present.

In evaluating the results of the blood cultures it is important to remember the following points: (1) a certain percentage of patients with bacterial endocarditis (estimated at between 10-15%) have consistently negative blood cultures, as in case 13[2]; (2) positive blood cultures may occasionally be obtained from normal individuals[1a] and from individuals with valvular heart disease who do not have endocarditis,[3] as in cases 1 and 10; and (3) when endocarditis exists, the blood cultures are usually either all positive or all negative.[1a] These considerations, for example, cast some doubt on the significance of the single positive culture in case 1 when 28 other cultures were negative.

The patients in both cases 1 and 2 died of the consequences of active rheumatic carditis. In case 1 the clinical diagnosis was not made until the last weeks of the patient's life. In both cases the attending physicians were led to the diagnosis of bacterial endocarditis by a variety of incorrectly interpreted findings.

The diagnosis of rheumatic activity in patients with long-standing rheumatic valvular disease is difficult. The classic manifestations of the disease as it is seen in children are often absent in adult patients, especially in those in the southern part of the United States.[4] The diagnosis of rheumatic activity is made especially difficult by the lack of a precise definition and even a single pathognomonic clinical criterion. Histological evidence obtained from atrial appendages removed at the time of mitral valve commissurotomy correlates poorly with clinical and laboratory findings.[5] The various serologic tests, usually positive in rheumatic fever, are of some use in following the course of the disease but are not specific, can be positive in other diseases, and, in general, are of limited diagnostic significance.[6]

The diagnosis of rheumatic fever is essentially a clinical one. Joint manifestations, erythema marginatum, and subcutaneous nodules are extremely helpful when present, but, in our experience, such definite signs are usually lacking in the type of patient under discussion. Minor arthralgias are common but often are no more prominent than the skeletal symptoms of individuals acutely ill with bacterial endocarditis. Objective evidence of joint involvement should, however, be considered clinical evidence of the highest order for the existence of rheumatic disease. In patients with long-standing rheumatic heart disease, fever and progressive cardiac failure may be the only signs of active rheumatic myocarditis. In retrospect, it is easy to see that fever and heart failure were the predominant manifestations throughout the courses of the patients in cases 1 and 2. Atrial fibrillation, associated with unusual difficulty in controlling the ventricular rate with digitalis, suggests active myocarditis. In the past there was a clinical axiom that bacterial endocarditis did not develop in patients with atrial fibrillation. Although it is clear that this axiom is not invariable, bacterial valvulitis does occur less frequently in these patients and, in general, in the advanced stages of valvular heart disease.

A therapeutic trial of aspirin is a dubious method for diagnosis of active rheumatism. In case 1 such a trial seemed helpful in that a fall in temperature and pulse rate and improvement in the degree of cardiac compensation accompanied the second course of aspirin. In contrast, there was no fall in temperature in the patient in case 2 when she was given 4.8 Gm. of aspirin a day, a dose which produced symptoms of salicylate intoxication. This lack of response was taken as evidence against active rheumatic fever and led to the diagnosis of bacterial endocarditis.

Whenever possible, therapeutic trials of antibiotic therapy should be avoided, as they are rarely helpful and often confusing. Antibiotics are frequently given to patients with fever and valvular heart disease on the basis of a presumptive diagnosis of bacterial endocarditis. It is impossible not to attach at least some diagnostic significance to the response of fever to this therapy, but this can be hazardous whether the temperature rises, falls, or remains unchanged. Body temperature is usually selected as the sign to follow for response to therapy, because it can be measured easily, graphed, and treated quantitatively. It is not, however, the only sign of therapeutic success in the treatment of bacterial endocarditis. Weight gain without heart failure, increase in appetite, and a general sense of well-being, though more difficult to evaluate, are possibly more reliable indexes of progress.

In the patients in cases 1 and 2, minor falls in temperature which coincided with antibiotic administration were taken as evidence corroborating the diagnosis of bacterial endocarditis. In case 1, after penicillin in a dosage of 6 million units per day had been administered for several days with no sustained fall in temperature, it was assumed that the dosage was inadequate. The dosage was doubled, and the temperature fell to the normal range. This sequence of events was taken as further confirmation of the diagnosis of bacterial endocarditis. A similar, although less impressive, response was interpreted as evidence for endocarditis in case 2.

Occasionally it is necessary to institute treatment for bacterial endocarditis without bacteriological confirmation of the diagnosis. In evaluating response to therapy, the following possibilities must be kept in mind: subsidence of fever may indicate the existence of endocarditis, or it may be only a chance variation in the course of another disease. Continued fever may indicate that the dosage is inadequate, that the correct drug is not being used, that the diagnosis is incorrect, or that the patient has developed a febrile reaction to the therapeutic agent.

As yet, the experience with the combination of antibiotics and adrenal corticoids in patients with subacute bacterial endocarditis is too limited to justify any final conclusion about either benefits or risks. Our personal experience is limited to a single patient in whom the administration of cortisone for a penicillin reaction had no evident adverse effect on the course of the subacute bacterial endocarditis treated concurrently with large doses of penicillin. In the literature good results are reported by some[7] and poor results by others.[8]

Drug Fever

Febrile reactions to antibiotics are largely responsible for the confusion associated with therapeutic trials. Penicillin, the most commonly used agent in the treatment of bacterial endocarditis, is capable of producing fever in at least two ways. When the fever rises gradually after a period of a week or more of intramuscular administration of penicillin, sterile inflammation at the injection sites should be suspected. In case 2, tenderness at the injection sites facilitated the diagnosis of chemical myositis. Often the patient does not complain, and it is only by careful palpation that the indurated, slightly tender areas of myositis are detected deep in the muscle. The diagnosis is confirmed by the gradual defervescence which accompanies the substitution of the intravenous for the intramuscular route of administration.

Fever caused by penicillin does not present a diagnostic problem when accompanied by a rash, but fever is often the only manifestation of hypersensitivity to the drug and prompt defervescence may follow its withdrawal. The serum sickness type of reaction[9] characterized by myalgia, arthritis, lymphadenopathy, and splenomegaly often closely simulates rheumatic fever and, therefore, assumes special significance in patients in whom rheumatic activity is always a definite possibility.

Fever may result from the use of many other drugs commonly employed in the management of patients with valvular heart disease. Febrile reactions to quinidine, procaine amide, and mercurial diuretics have been reported. In one of our patients, quinidine was responsible for fever, petechial hemorrhages, and splenomegaly—a clinical picture closely simulating bacterial endocarditis. To our knowledge, digitalis has never been proved to be responsible for drug fever, although urticaria has been observed[10] and we have recently seen erythema multiforme in a patient who received separate administrations of digitalis leaf and digitoxin.

Evaluation of Embolic Lesions

Petechial hemorrhages, embolism in retinal vessels, and "splinter hemorrhages" under the nails are important signs in patients with valvular heart disease. These lesions, commonly referred to as hemorrhagic or embolic, are usually thought to be pathognomonic of bacterial endocarditis, and often a prolonged course of penicillin therapy has been started because of one splinter hemorrhage or one shower of petechiae. These lesions are of great significance and should be diligently sought, but caution must be exercised in their interpretation.

Hemorrhagic and embolic lesions appeared periodically in patients in cases 1 and 2, and yet neither patient had bacterial endocarditis. These lesions have been noted in other patients with active rheumatic fever and in patients with the postcommissurotomy syndrome (case 11). A strikingly similar case has been reported in which splenomegaly, hematuria, and petechiae were seen in a patient dying of rheumatic carditis.[11] Petechial lesions and splinter hemorrhages may occur on the basis of the rheumatic process alone and in the absence of bacterial vegetations of the heart valves. The lesions may be the result of sterile embolization from fibrillating atria or rheumatic valvulitis or may represent a local vascular component of the rheumatic process. In two patients (cases 18 and 19) with long-healed bacterial endocarditis, splinter hemorrhages have been seen with no evidence of active infection, and it is presumed that sterile emboli from healed vegetations were responsible. Sterile emboli were apparently responsible for typical Roth's spots in the retinas in another patient (case 6) who did not have bacterial endocarditis.

Petechiae or splinter hemorrhages may occur from trauma, for example, in the oral cavity from ill-fitting dentures or in the nail beds from injury. Reactions to drugs, with or without thrombocytopenia, may be accompanied by hemorrhagic lesions, which, when few in number, may suggest bacterial endocarditis. Before petechial lesions are attributed to embolism it should be demonstrated that the blood coagulation mechanism is functioning normally. The hepatic congestion of heart failure can be accompanied by a prolonged prothrombin time and excessive bleeding. In case 2 the prolonged prothrombin time was attributed to the "bishydroxycoumarin-like" effect of aspirin superimposed on the impaired hepatic function resulting from congestion. This increased sensitivity of the congested liver to bishydroxycoumarin and aspirin is especially important, as both of these drugs may be given in the situation under consideration. Frick[12] attributes the bleeding tendency to a direct effect of salicylates on capillaries. The thrombosis of the great veins which occurred in case 2, while an unusual complication, occasionally develops with severe heart failure.

In both cases 1 and 2, old and recent pulmonary emboli were present. This finding is very common in patients dying with chronic rheumatic heart disease, particularly when atrial fibrillation has existed for an appreciable period (cases 4, 15, and 17). Pulmonary embolism without accompanying rheumatic myocarditis was a "good diagnosis" in case 1. The history of recurrent bouts of pneumonia suggests previous episodes of embolism. If the emboli are small, the classic signs and symptoms, such as cough, hemoptysis, friction rub, and typical x-ray changes, may be absent. As the pulmonary vascular tree is progressively occluded by embolization, chronic right ventricular failure can develop and the slowly developing pulmonary vascular obstruction may have effects resembling those of rheumatic myocarditis. Fever, progressive and uncontrollable heart failure, and tachycardia are sometimes the only manifestations of recurrent pulmonary embolism.

In cases 1 and 2 petechiae and splinter hemorrhages were encountered in association with active rheumatic carditis. Splenomegaly, another finding often considered specific for bacterial endocarditis, also occurs in patients with rheumatic heart disease in the absence of bacterial endocarditis.[13] Congestive heart failure or splenic infarction explains some, but by no means all, of these instances of splenomegaly. In cases 7, 9, and 15, and in cases reported by others, active rheumatic fever seemed, even at autopsy, to be the sole basis for the splenic enlargement. The patient in case 9, a 19-year-old boy who died with active rheumatic carditis, also had marked digital clubbing, perionychial erythema, and hematuria—all features commonly associated with bacterial endocarditis.

In cases 1 and 2 presented above, rheumatic myocarditis simulated bacterial endocarditis. In the case (case 14) below, an unusual complication of bacterial endocarditis led to the mistaken diagnosis of rheumatic myocarditis.

CASE 14.—An 18-year-old boy had developed fever, malaise, and fatigue five months prior to admission. He was admitted to another hospital where two blood cultures were positive for nonhemolytic streptococci and 47 million units of penicillin were administered over a period of 78 days. After discharge, the patient did well until two weeks prior to readmission, when he developed fever and pain in the joints. He was readmitted to the same hospital and given a short course of penicillin and tetracycline and then transferred to the Johns Hopkins Hospital.

He was found to have mitral stenosis and regurgitation. He was afebrile on admission, the peripheral leukocyte count was 9,800 per cubic millimeter, and the erythrocyte sedimentation rate was 21 mm. per hour. A rare erythrocyte was seen in the urine, but there was no albuminuria. Eleven blood cultures were sterile. On the seventh hospital day the patient awoke with severe precordial pain, which persisted for three hours and was accompanied by a fall in blood pressure. On the following day the temperature rose to 102 F (38.89 C), the peripheral leukocyte count rose from 7,800 to 27,000 per cubic millimeter, and a pericardial friction rub appeared. Electrocardiograms showed no significant change from that on the admission record. It was felt that this sequence of events was best explained by either a coronary embolus or acute rheumatic myocarditis and pericarditis. Treatment with hydroxy phenyl cinchoninic acid (an aspirin-like agent then under investigation) was instituted, resulting in the prompt fall of the temperature and leukocyte count to normal. The patient was discharged, essentially asymptomatic to convalesce at home. However, heart failure developed after discharge, and he returned after one month.

On readmission he was in severe heart failure. This was interpreted as a manifestation of progressive rheumatic myocarditis. He was afebrile on admission, but the temperature reached 101.4 F. (38.6 C) on the fifth hospital day and rose to approximately this level on each of the next three days. The peripheral leukocyte count was 12,000 per cubic millimeter, and the erythrocyte sedimentation rate was 7 mm. per hour. In one of the three urine specimens examined one red blood cell was seen, and in others a trace of albumin was noted. Three blood cultures were sterile. The patient died after one week in the hospital. At autopsy, vegetations containing microscopically demonstrable bacteria were found on the mitral valve. There were multiple subacute focal infarcts of the right and left ventricles and subacute rheumatoid endocarditis.

The combination of fever, leukocytosis, and pericardial friction rub in a patient with rheumatic heart disease most often indicates rheumatic pancarditis. In this case, however, while lesions of subacute rheumatic endocarditis were present at autopsy, the primary myocardial disease was infarction secondary to coronary embolism.

Miscellaneous Causes of Fever

In most patients with fever and valvular heart disease, rheumatic fever, bacterial endocarditis, drug fever, or embolism will be found to explain the fever. There are, however, several more unusual febrile disorders that deserve consideration in relation to these patients.

Congestive failure is included merely to state that per se it probably never produces sufficient fever to be important in the type of patient being discussed.[14] Oral temperatures of 99-100 F (37.22-37.78 C) may be attributed to congestive failure, but for fever of greater magnitude other explanation must be sought.

Systemic Lupus Erythematosus.—A 44-year-old man (case 22) was seen at autopsy to have had systemic lupus erythematosus manifested by mitral stenosis, fever, clubbed fingers, hematuria, splenomegaly, and petechial rash. The clinical diagnosis had been bacterial endocarditis, and, although blood cultures were negative, he received treatment for this infection. A circulating anticoagulant was present in this patient and contributed to petechial and other hemorrhagic manifestations. It is important to remember that lupus can produce valvular heart disease and that the manifestations of acute systemic lupus may simulate bacterial endocarditis and rheumatic fever.

Hemoglobin Pneumonia.—Hemoptysis is a familiar event in mitral stenosis. Rupture of bronchial varices is usually responsible; however, repeated massive hemoptyses associated with elevations of temperature may result from extensive rheumatic pneumonia and pulmonary vasculitis. Occasionally the aspiration of blood into the lung after a bronchial hemorrhage produces a clinical picture which may include fever as a leading feature. Shaking chills are not infrequent at the onset. Leukocytosis, elevation of the sedimentation rate, and mild bilirubinemia may be observed. Pronounced apprehension is rather characteristic and often develops without apparent reason before the other signs.[15] These attacks are usually nocturnal and often follow unusual exertion during the day.

Hemoglobin pneumonia is a satisfactory term for the generalized illness these patients may have. Patients often have physical and x-ray signs as a result of aspiration of blood into the lung, but these are not always present. Infiltrations concentrated at the base of the right upper lobe overlying the fissure are common, suggesting that the laws of "bronchial embolism" as defined by Brock apply here. Sometimes the pulmonary shadows fan out from each hilum in a "butterfly" pattern; this may be the result of a concomitant pulmonary edema.

The mechanism of bilirubinemia is not clear, but it is probably similar to that responsible for icterus with pulmonary infarction. The pronounced systemic reactions—chills, fever, leukocytosis—may well be a response to altered blood in the airways. In many of these cases very little blood is necessary to evoke the reaction, thus suggesting that hypersensitivity plays a role. Pulmonary infarction obviously can produce much the same clinical picture and, of course, is frequent in patients with mitral stenosis. Usually, however, these two disorders can be distinguished from each other. Hemoglobin pneumonia represents a discreet entity worthy of consideration.

A striking case of hemoglobin pneumonia was that of the patient in case 21, a 39-year-old man with mitral stenosis who had been having intermittent attacks of shortness of breath and fever at night for two years prior to hospital admission. He had been studied at three different medical centers, and, because of fever, the diagnosis of endocarditis had been made despite the fact that all blood cultures were negative. He had received 381 million units of penicillin, but the attacks continued to occur while he was receiving antibiotic therapy. A typical nocturnal episode was characterized by apprehension, tachycardia, fever to 103 F (39.44 C), and leukocytosis of 23,500 cells per cubic millimeter. This was most likely to follow a day of unusual exertion. All the signs and symptoms subsided within 12 hours. The patient had a mitral valvulotomy for relief of pulmonary hypertension and when last heard from, one year after operation, reported amelioration of these symptoms.

Fever from Ball-Valve Tumors.—It is not generally appreciated that intracardiac tumors and thrombi may cause the presenting symptom of fever. One patient (case 24), when she was admitted to the hospital, had signs of rheumatic mitral stenosis and a low-grade fever. The major diagnostic possibilities were rheumatic fever and bacterial endocarditis, and both aspirin and penicillin were administered without effect. At autopsy, a pedunculated ball-valve thrombus was found in the left atrium and there was evidence of both recent and old pulmonary embolism. Fever and signs of peripheral embolism were prominent features in two other patients (cases 23 and 25) who proved to have myxoma of the left atrium with multiple tumor emboli. It seems probable that the fever in these patients arises in part from the process of embolization. The combination of fever, heart murmur, and peripheral embolism frequently leads to the mistaken diagnosis of bacterial endocarditis. At least one similar case of fever with auricular tumor has been described.[16]

Comment

Patients with valvular heart disease and fever present difficult problems in differential diagnosis and management. Bacterial endocarditis should properly be given first consideration when fever and a heart murmur coexist. Without deemphasizing the importance of bacterial endocarditis, one should also direct attention to other conditions which closely simulate it. Petechial lesions, splinter hemorrhages, clubbing of the fingers, and splenomegaly can appear during the course of active rheumatic fever. These lesions are not specific for bacterial endocarditis. Rheumatic myocarditis may be fatal if untreated. In cases in which the differentiation between rheumatic activity and bacterial endocarditis cannot be made with certainty and in which the patient is gravely ill, therapy probably should be directed at both diseases.

HEMIPELVECTOMY FOR MALIGNANT DISEASE

Royce C. Lewis Jr., M.D.
and
William H. Bickel, M.D., Rochester, Minn.

The results of amputating an entire lower extremity with the corresponding half of the pelvis for malignant disease in 50 patients seen before the end of December, 1954, are reviewed for the purpose of assessing the therapeutic value of the operation and identifying the factors that affect immediate surgical mortality. No hospital deaths occurred, but in 1955 a hospital death followed operation. It resulted from pulmonary embolism on the seventh postoperative day. This extremely low mortality is ascribed to the relatively short duration of the operative procedure (which averaged 2¼ hours), to the general supportive care given to the patient, and to the replacement of lost blood. A tracheal tube was used by the anesthesiologist in every case. The surgeon must avoid seeding the wound with tumor cells, and transabdominal biopsies of tumors of the os coxae during exploratory laparotomy or through the incision made at the time of hemipelvectomy are strongly condemned. The life expectancy of the patient depended on the type of diseases that necessitated operation, and the best postoperative survival rate was in the group of patients with chondrosarcoma.

Though the first successful transiliac amputation or hemipelvectomy was done by Girard[1] in 1895, it has been in only comparatively recent years that the making of a diagnosis of a malignant neoplasm of the bones or soft tissue of the pelvis and upper part of the thigh did not almost invariably amount to the signing of the patient's death warrant. The first resection was attempted in 1891 by Billroth.[2] His patient died in shock, as did several others on whom resection was attempted before Girard performed that first successful hemipelvectomy in 1895. As late as 1935, Gordon-Taylor and Wiles[3] were able to find in the literature only 79 reported instances of treatment by hemipelvectomy, with 46 operative deaths. The largest single group of cases to date is that reported by Gordon-Taylor and Munro[4] in 1952. They presented information on a total of 64 cases, with 14 deaths, or an operative mortality of 22%. It should be pointed out, however, that operations were performed in 11 of their cases prior to 1940 under conditions somewhat less favorable from the standpoint of supportive care than those enjoyed today. Four of these 11 patients died (36%), whereas 10 of 53 patients operated on after 1940 died, an operative mortality of only 19%.

The Series and Operative Mortality

The first hemipelvectomy at the Mayo Clinic was performed in 1943; in 1946, Beck, with one of us (W. H. B.),[5] reported 12 cases in which the operation was done at this clinic with no operative deaths. Through December, 1954, this series has been extended to 50 cases in which hemipelvectomy has been performed for malignant neoplasms of the pelvis and upper part of the thigh, still without an operative death. Hemipelvectomy was performed also during this time in two cases for intractable, advanced osteomyelitis of the innominate bone with multiple draining sinuses. Both of these patients recovered and are completely well. These two cases are not included in the 50 cases which form the basis of this report. Thirteen additional operations have been done but are not included in the series because of the brevity of follow-up. One of the patients operated on in 1955 died of pulmonary embolism on the seventh postoperative day. He had been ambulatory for several days prior to his death. This has been the only hospital death in the total of 65 cases in which hemipelvectomy has been done prior to Jan. 1, 1956, at the Mayo Clinic.

Explanation for this extremely low mortality lies in several factors. Foremost of these is the excellent supportive therapy tendered by the members of the section of anesthesiology. Careful attention must be given to replacement of the blood lost, and even mild shock cannot be tolerated, since in a procedure of the magnitude of hemipelvectomy it may rapidly become irreversible. A total of 120,500 cc. (about 30 gal.) of blood was given to the 50 patients either during or immediately after operation, a rough average of 2,410 cc. (5 pt.) each. The most blood given to any one patient was 7,000 cc. and the least 1,000 cc. Levarterenol or ephedrine was given if necessary. A tracheal tube was used for all these patients so that respiration could be under the direct control of the anesthesiologist at all times.

Another important factor in maintaining low operative mortality is the duration of the operative procedure itself. The average operating time in all 50 cases was 2¼ hours, with the longest being 3½ and the shortest 1⅓ hours. In 13 of these cases the operat-

ing time was less than two hours, and in only 7 was it more than three hours. It is obvious that the alarm reaction and stress mechanism of the patient are much more severely taxed by extremely long procedures, even with excellent supportive care; it must be remembered too that a difference of even one or two hours makes considerable difference (1) in the total amount of anesthetic agent given, (2) usually in the total quantity of blood lost, and (3) most certainly in the likelihood of postoperative complications.

Operative Technique

The operative technique described by King and Steelquist[6] was followed in most cases, although alterations were made as the occasion arose. In cases of tumors arising in the buttock, it was oftentimes necessary to form anterior instead of the standard posterior flaps in order to avoid the tumor. In a few of the cases in which tumors of the innominate bone protruded into the abdomen, a general surgeon assisted in the abdominal phase of the operation.

In all 50 cases, primary closure with rubber drains of the Penrose type was employed, with removal of the drains in 48 hours. Several of the stumps were slow in healing and drained for a week or two after operation, but in only three instances was healing a problem. In one case a large hematoma developed; it was evacuated repeatedly but re-formed. Finally, the margins of the flap were opened inferiorly, the defect was packed open, and the area was allowed to fill in by granulation. In the two other cases the margins of the flaps sloughed and skin grafting was necessary before final healing could be accomplished.

Injury to the genitourinary organs occurred in only one case, in which the urethra was lacerated when the pubic bone was removed. The defect in the urethra was immediately repaired by a urologic surgeon who was called in, and, except for the inconvenience of an indwelling catheter while healing took place, no difficulty was experienced and no sequelae were observed.

Perhaps the most important point in technique is emphasized by the fact that in 14 of the 25 patients who have died since operation, and in 2 of the patients who are now known to have metastases, seeding of the wound with tumor cells was known to have occurred at the time of operation. This resulted from (1) taking of a biopsy specimen through the future operative site before hemipelvectomy or through the operative site at time of hemipelvectomy; (2) the necessary removal of huge tumors in pieces which made it impossible to avoid some seeding with tumor cells, (3) adherence of the tumor to vessels, peritoneum, intra-abdominal organs, or tissue, such as parts of the sacrum that could not be removed, (4) incomplete removal of a tumor as a palliative procedure in cases in which it was obvious at the time of operation that complete removal was impossible, and (5) accidental opening of the tumor in the course of the operation.

No patient who now is living and without metastases is known to have had seeding of the wound with tumor cells; all patients in whom seeding is known to have occurred have either died or have definite evidence of recurrence. In one case, transabdominal biopsy of a chondrosarcoma of the ilium was carried out elsewhere, and, though the surgeon suspected that seeding had occurred at the time of the previous operation, this was not known for certain. This patient, contrary to the usual story, is living 12 months after operation and is without known metastases.

The removal of tissue from tumors of the innominate bone for microscopic examination and diagnosis at the time of exploratory laparotomy is to be deplored, as such practice often precludes any chance of complete eradication by hemipelvectomy later. The seriousness of the situation can usually be determined before operation and the patient's permission for radical operation obtained. Then, at operation, an approach suitable for biopsy can be employed. If the frozen section of the tissue removed reveals a malignancy, definitive treatment can be instituted immediately and the tissue near the incision used for the biopsy can be included in the portion removed. In this way, seeding the remaining tissues with tumor cells is avoided.

Duration of Symptoms and Survival

From a clinical standpoint, the 50 patients, for the most part, presented the symptoms and signs which would be expected from neoplasms of the pelvis for which hemipelvectomy was necessary. The usual symptoms were pain, mass, loss of motion in the hips, signs of nerve pressure and vascular pressure, and in some cases dysfunction of the bowel or bladder.

Of much more significance than the type of symptom presented, however, was the duration of the symptoms. Although some of these neoplasms are relatively slow growing and hence might show a good incidence of cure—even with symptoms of relatively long duration—for the most part, the shorter the time between onset of symptoms and removal of the tumor by hemipelvectomy, the better the chances of survival for the patient. Twelve of the 18 patients who had had symptoms less than six months at the time of operation are still living (two with metastases), and 4 of the 6 who had had symptoms for six months to one year are still living (one with metastases), while only 8 of the 25 patients who had had symptoms for more than one year have survived the present follow-up periods, and one of these has evidence of metastases.

A total of 25 of the original 50 patients who underwent hemipelvectomy are still living, though 4 of this group have generalized metastases. Discounting these four, the follow-up interval for these living patients ranges from the shortest period of five months to the longest of 11 years and eight months. In seven cases the follow-up period was five years or more; in three it was between four and five years; in one, between three and four years, in two, between two and three years; in four, between one and two years; and in four, less than one year. The four patients with generalized metastases were living 22, 13, 6, and 2 months after operation when follow-up information was obtained.

Of the 25 patients who are dead, 13 did not survive the first year following hemipelvectomy, four lived one to two years, one lived about three years, five lived three to four years, and two lived six years and five years and five months, respectively, before dying of the neoplasm.

Selection of Patients for Operation

With adequate follow-up data now available on 50 patients, some conclusions may be drawn which may help to evaluate the efficacy of such a radical procedure as hemipelvectomy. Certainly the decision to recommend a hemipelvectomy must be the result of careful weighing of the many aspects by the surgeon who suggests such a course of action and by the patient before deciding to have it done. Aside from the immediate danger of loss of life during the procedure itself, a patient faces, on occasions, a rather stormy postoperative period and sometimes a prolonged convalescence, especially when any difficulty in wound healing is experienced.

TABLE 1.—*Survival After Hemipelvectomy, by Type of Lesion*

* 1 has metastases.
† 2 have metastases.

The disability associated with the loss of an entire lower extremity is not slight. The patient who has been engaged in active physical work is faced with the inability to return to this type of work, no matter how agile he may become on crutches or with use of a prosthetic appliance. Adjustments in his daily life must be made because the type of prosthesis available leaves much to be desired, particularly for older and heavier individuals. Driving a car presents problems in some instances. Bowel and bladder dysfunction, while not a prominent problem in our series, are certainly sequelae to be considered and can b disabling when they do occur. The third factor to b considered in elective hemipelvectomy is the tremen dous psychic trauma associated with a mutilatin procedure of this type. Many patients who can adjus to the idea of amputation of a leg are someho unable to accept emotionally the loss of half of thei pelvis as well, even though the resulting disabilit is almost the same.

It becomes obvious from the foregoing that carefu consideration of each patient is imperative in selectio of cases for hemipelvectomy. Not only must the surgeon assure himself to the best of his ability tha distant metastases do not exist, but also he must weig the operative mortality, stormy postoperative cours prolonged convalescence, resultant disability wit the chance of sequelae, and psychic trauma agains the possibility of obtaining a cure by this procedur Since most patients will gladly accept the disadvantages for a reasonably good chance of permanen eradication of the tumor, consideration of the likelihood of cure in the different types of tumors i pertinent.

Survival as Related to the Type of Neoplasm

From a pathological standpoint, our patients wer divided into two large groups, namely, those wit primary tumors of bone and those with malignan neoplasms of soft-tissue origin. Tumors of 32 patient arose from bone. Of these 32 patients, 16 are living although one has generalized metastases. These neoplasms of bone were of three general histologica types: chondrosarcoma, osteogenic sarcoma, an reticulum-cell sarcoma (table 1).

The largest histological group of bone tumors wa that of chondrosarcomas. Of the 22 patients in thi group, 13 are living, including the one with generalized metastases previously mentioned. Follow-u periods in this group included the longest of 11 year and eight months without signs of recurrence, an the shortest of five months. Histologically, the chondrosarcomas were graded according to the classification of Broders, and the malignancy of all except one was found to be either grade 1 or 2 (table 2). Of th 10 patients with grade 1 malignancy, 5 are still living of the 11 with grade 2 malignancy, 7 are living. Th patient with the grade 3 chondrosarcoma is livin three years and eight months after operation withou signs of recurrence; and one of the patients wit grade 2 chondrosarcoma has generalized metastase only six months after operation.

The location of the chondrosarcoma seemed particularly significant. The primary site of the chondrosarcoma was the femur in 7 of the 22 patients, an only 1 of these 7 has died. This patient, who wa treated originally by disarticulation of the hip, ha a recurrence in the stump involving the ilium. Hemipelvectomy was performed because of the recurrenc one year later. Eight of the 15 patients with chondrosarcomas of the innominate bone have died.

Of the nine patients who had osteogenic sarcoma, only three have survived (table 1). Histologically, all three types of osteogenic sarcoma were represented in the group: one tumor was of the fibroblastic type (grade 2), two were of the osteoblastic type (grade 3 and grade 4), and six were chondroblastic osteogenic sarcomas, two of which were of grade 2 and four of grade 3 malignancy (table 2). Two of the three living patients who had osteogenic sarcoma had neoplasms of grade 2 malignancy, while the third had a typical grade 4 osteoblastic osteogenic sarcoma involving the entire upper part of the femur complicated by a pathological fracture. This last patient had one of the longest follow-ups in the series (nine years and two months) and apparently can be considered well.

One primary tumor of bone was a reticulum-cell sarcoma which involved the upper part of the femur, the innominate bone, sciatic nerve, femoral vessels, and femoral nerve. There was massive brawny edema of the entire extremity, with exquisite intolerable pain resulting from involvement of the nerve. Hemipelvectomy was done as a palliative procedure to relieve the excruciating pain and remove the greatly enlarged useless extremity. Intensive x-ray therapy was given to this ordinarily radiosensitive tumor, but the patient lived only seven months. Death was due to generalized involvement.

The second large group of neoplasms, the soft-tissue tumors, consisted of two main and several miscellaneous types. There were six fibrosarcomas, five liposarcomas, and seven in the miscellaneous group. Of the 18 patients in this group, 9 were living at the time of follow-up, but 3 of these had evidence of generalized metastases (table 1) The longest follow-up period in this group was eight years and four months and was for one of the patients with myofibrosarcoma. The shortest follow-up period was seven months and two others were less than one year.

Only one of the six patients with fibrosarcoma is living. This patient, who had a grade 4 neoplasm, is living 18 months after operation and does not have any signs of recurrence. Of the five patients with liposarcoma, the one with the lesion of grade 1 and all three of the patients with lesions of grade 3 are living, although two of the latter have evidence of metastases. One of these patients with a grade 3 liposarcoma had a solitary metastatic lesion in the lung 16 months after hemipelvectomy. Pneumonectomy was performed on the right. The patient is living nine months after this second operation, and, while definite proof of other metastatic lesions cannot be demonstrated, it is suspected that such lesions exist.

The miscellaneous group of soft-tissue tumors is listed in table 1. Of the seven patients in this group, the two with myofibrosarcoma and one of the two with neurofibrosarcoma are living and are without evidence of metastases. The patient with a hemangiopericytoma has evidence of extensive pulmonary metastases 13 months after hemipelvectomy.

From the foregoing, several general impressions may be gained. By and large, the greatest percentage of survivals for the follow-up period was in the group of patients having chondrosarcomas. This might be expected, since chondrosarcomas are usually of a lower grade of malignancy, and more clearly differentiated grossly, which allows greater success in attempts at complete removal. Furthermore, many of the soft-tissue tumors occurred relatively high in the buttock or groin, making removal of all malignant cells less likely, particularly when these tumors are ordinarily poorly demarcated. The importance of location of the tumor, even among the chondrosarcomas, has already been pointed out. It is impossible to attach significance to survival associated with lesions of different grades of malignancy within groups (other than between groups having characteristically different grades as a group), since complete circumstances are not known in some cases and the groups are not large enough to present statistically valuable data. There are instances of relatively long follow-ups of patients with neoplasms of grade 4, whereas patients with neoplasms of grades 1 and 2 of the same histological type lived only a few months.

TABLE 2.—*Survival After Hemipelvectomy, by Grade of Malignancy of the Bone Tumors and Three Soft-Tissue Tumors*

Postoperative Discomfort, Use of Prosthesis, Vesical and Bowel Dysfunction

From questioning the 25 survivors, it was learned that a relatively high percentage have experienced varying degrees of phantom pain. Although this phenomenon is an almost constant finding during the first few weeks after operation, the discomfort is usually of only short duration. Five of the patients stated that they had occasional mild pain that seemed to arise from the amputated extremity. These episodes had occurred periodically throughout the follow-up period.

Six others classified their discomfort as moderate and more or less constant. The pain was described as severe by four, being so severe in one as to require chordotomy for relief. In only these four cases has the pain been severe enough to be disabling per se. There were no symptoms of bowel or bladder dysfunction in any of the patients comprising this series with the exception of the case mentioned in which chordotomy was done because of persistent pain.

Only two of the patients stated that they routinely use a prosthesis, though two others mentioned that they had tried various prosthetic appliances and had found none satisfactory. The remainder of the survivors have not tried to use a prosthesis, either on advice of the limb maker or because of their own disinclination. Many of these patients have felt that they fared so well on crutches that they did not believe that any type of prosthetic appliance could offer additional comfort or function.

The local physician of one of the patients reported that the patient became pregnant some months after operation, enjoyed a relatively uneventful pregnancy, and spontaneously delivered a normal, healthy child. It is now three years and eight months since hemipelvectomy was done on this patient for grade 3 chondrosarcoma of the upper part of the femur.

Conclusions

On the basis of 50 cases in which malignant neoplasms of the pelvis and upper part of the thigh were treated by hemipelvectomy at the Mayo Clinic, the following points seem worth stressing:

1. The chances of survival are definitely improved by early recognition and operation soon after discovery of the tumor.
2. Chances for survival seem much greater in the slower-growing neoplasms, but anaplasia per se is not a contraindication, since some of the longest survivals in the series have been among patients with neoplasms of grades 3 and 4.
3. Location is an important factor in determining chances for survival, since tumors that can be removed *in toto* with a wide margin of normal tissue offer the best chance of complete eradication. This is best illustrated by the fact that the percentage of survivors among those who have had chondrosarcomas occurring in the upper part of the femur was much greater than among those who have had chondrosarcomas arising primarily from the innominate bones.
4. The highest percentage of survivals was in the group of patients with chondrosarcoma. This is thought to be due to the fact that as a group chondrosarcomas are usually of lower grade and are slower growing than other neoplasms removed. In addition, when they occur in the upper part of the femur, they often offer a wider margin of normal tissue and hence an excellent chance of cure in this location.
5. Transabdominal biopsy of tumors of the innominate bone at the time of exploratory laparotomy and biopsy of lesions through the same incision as that contemplated for hemipelvectomy are to be strongly condemned, since the chances for complete eradication are materially lessened because the procedures almost invariably allow seeding of the remaining tissue with tumor cells.
6. Operative mortality can be greatly lessened by careful supportive therapy, including meticulous replacement of blood, and by maintenance of a minimal operating time.

The Return of the Patient.—Every doctor is interested in rehabilitation. That is what he means by the word "cure." By that term he means the relief of symptoms, the restoration of function and the return of the patient to his job, to his family, and to the community as a normal person. In the case of appendicitis, simple fracture or pneumonia, the doctor can achieve this end result with his own bare hands. When a person has lost a leg by amputation, suffered injury to the spinal cord, with paraplegia, or to the brain, with hemiplegia, however, the doctor needs not only his two hands but other hands as well. Unless the doctor's efforts are supplemented by the work of paramedical personnel, such a patient will be left permanently disabled, a burden to the family and community, and unable to assume his rightful place in society. . . . The philosopher Paulsen said that the object of all help is to make help superfluous. This is the ideal that has pointed the way to surgeons. It is an ideal that can be realized only when surgeons assume a fierce belief in their individual responsibility for what happens to their fellow men.—Henry H. Kessler, M.D., Rehabilitation of the Amputee, *Journal of the International College of Surgeons*, September, 1956.

PREDNISONE AND PREDNISOLONE THERAPY IN RHEUMATOID ARTHRITIS

CLINICAL EVALUATION, WITH EMPHASIS ON GASTROINTESTINAL MANIFESTATIONS IN ONE HUNDRED FIFTY-SIX PATIENTS OBSERVED FOR PERIODS OF FOUR TO FOURTEEN MONTHS

Bertrand L. Stolzer, M.D., James H. Barr Jr., M.D., Carl H. Eisenbeis Jr., M.D., Richard L. Wechsler, M.D.
and
Harry M. Margolis, M.D., Pittsburgh

Rheumatoid arthritis was treated in 156 patients by oral administration of either prednisone or prednisolone. The initial dosage ranged from 10 to 40 mg. per day, given in divided doses at approximately six-hour intervals. In most patients, 10 mg. or less per day sufficed for maintenance. Therapy was continued for periods ranging from 4 to 14 months. Observations showed general improvement in the patients by subjective and objective criteria; functional capacity was increased, and 38 of the 59 adult male patients were enabled either to return to work or to continue their work status. Side-effects of these drugs were, in general, not disturbing, but the incidence of gastrointestinal complaints increased from 11 to 21%. Peptic ulcers appeared in some patients in whom the roentgenograms had not shown such lesions before treatment. Among five patients who developed complications of peptic ulcer, three developed hemorrhages and two suffered perforations. Because these complications offset somewhat the undeniable benefits of the prednisone and prednisolone to arthritic patients, there is urgent need for the development of drugs that will be equally effective and less marred by side-effects.

Six years of experience with corticotropin (ACTH) and adrenal cortical steroids in the management of rheumatoid arthritis has reemphasized the importance of a basic therapeutic program, which includes adequate rest, physical therapy, salicylates, relief from various types of physical and emotional stress, analgesia and sedation.[1]

In a clinic to which persons with more advanced rheumatoid arthritis and those who are more seriously ill are referred, conservative management, even diligently applied, may not suffice. Sustained progression of the rheumatoid process, increasing incapacity of the individual, and pressing socioeconomic need for earliest functional rehabilitation may force the clinician to add an adrenal cortical steroid to the basic therapeutic regimen.

In our practice the steroids have not been used as substitutes for the basic program of management, but rather as a supplementary measure. Although our emphasis in this presentation is on the clinical evaluation of the steroid effect, the common denominator of therapy was, in all instances, a relatively uniform program of general measures.

Prednisone and prednisolone, employed in the management of rheumatoid arthritis for nearly two years, have demonstrated the value of their antiphlogistic effect in this disease.[2] By clinical appraisal, the antirheumatic potency of prednisone, per milligram, generally averages four times that of hydrocortisone.[3] With amelioration of the manifestations of the disease, there is often increased functional capacity of the individual. Undesirable physiological effects have, however, been noted with prednisone as with cortisone and hydrocortisone.[4]

We are, therefore, attempting an appraisal of the value of prednisone by evaluating our experience in 156 patients with rheumatoid arthritis in whom prednisone (or prednisolone) was employed in an office and hospital practice from December, 1954, to the time of writing. We hoped that our data might shed some light on the following questions: What is the indication for the use of this steroid? What is the optimal dosage? What positive therapeutic effects may be expected? What undesirable effects may be anticipated? What measures may be taken to prevent or manage the undesirable effects which develop? What conclusions are justified with regard to the place of these steroids in the management of rheumatoid arthritis?

Composition of Clinical Material

Prednisone was administered chiefly to patients with far-advanced, severe, but potentially reversible rheumatoid arthritis. Others were patients with early, milder, but unequivocal rheumatoid arthritis, in whom functional rehabilitation, which was a pressing necessity, could not be achieved by a fair trial of conservative measures alone.

Sixty patients were male; 96 were female. The ages ranged from 9 to 79 years. The majority of the patients (71%), were between 40 and 60 years of age.

From the Department of Medicine, School of Medicine, University of Pittsburgh, and the Saint Margaret Memorial and Montefiore hospitals.

In 46% of the cases, the duration of the arthritis was from 3 to 15 years. Twenty-seven per cent of the patients had had their disease over 15 years.

Six per cent of the patients were in stage 1 of their disease, according to the Steinbrocker classification.[5] Twenty-four per cent were in stage 2, 52% in stage 3, and 18% in stage 4. Prior to the institution of prednisone therapy, 63% of the patients were taking either cortisone or hydrocortisone. Seventeen per cent were receiving salicylates, and 20% were receiving phenylbutazone (Butazolidin) or chrysotherapy, with unsatisfactory response.

DURING PREDNISONE THERAPY

BEFORE PREDNISONE THERAPY

GRADE	I	II	III	IV	TOTAL
I					
II	18	42	2		62
III	2	67	21		90
IV		1	1	2	4
TOTAL	20	110	24	2	

Fig. 1.—Activity of rheumatoid arthritis, graded from 1 to 4, in increasing order of severity. Unstippled area shows number of patients in whom improvement with prednisone was sufficient to justify a lower grading.

Mode of Administration

In the majority of the patients (94% of the group) the initial dosage ranged from 10 to 40 mg. of prednisone or prednisolone per day, given in divided doses at approximately six-hour intervals. In 49% of the group the dosage range was 10 to 20 mg. daily. In five cases, dosages of 60 to 90 mg. daily were administered for periods of less than a week. The dosage was then adjusted according to the particular requirements of the patient. For maintenance therapy, 10 mg. or less of the drug per day was used in the majority of patients. At the time of analysis of our results, the duration of therapy ranged from 4 to 14 months. Eighty-two per cent of the patients have been observed while on prednisone therapy for at least an 8-month period and 66% over a 10-month period.

Results of Therapy

The results of therapy were evaluated from three points of view. The first was grading of the over-all improvement in the total activity of the disease as judged by composite evaluations of improvement in subjective and objective manifestations, general constitutional reaction, and the usual routine laboratory data. The next was the improvement in functional capacity of the individual. The third was the ability of the 59 adult male patients to either return to work or continue their work status.

Figure 1 presents an evaluation of the activity of the disease, relating the patient's status prior to treatment with his status on prednisone therapy. The degree of severity is graded from 1 to 4, in increasing order of severity. Prior to therapy, no patient was considered to have disease of grade 1 severity. During therapy 20 patients were so classified. Eighty-nine patients (57% of the total group) improved at least one grade with prednisone therapy.

Figure 2 shows the functional classification before and during therapy, according to Steinbrocker and others,[5] with severity of impairment classed from 1 to 4. Before treatment with prednisone there were no patients in class 1; during therapy 26 patients moved into this classification. Prior to therapy, eight patients were considered to have class 4 impairment; that is, they were partially or totally dependent upon others for basic activities of daily living. With therapy, only three remained in this classification. Sixty-four patients (41%), represented in the unstippled area in figure 2, improved sufficiently with prednisone to justify a higher functional classification.

Fig. 2.—Effect of prednisone therapy on functional capacity (classification according to Steinbrocker and co-workers [5]). Unstippled area shows number of patients in whom improvemen with prednisone was sufficient to justify a lower classification

An analysis of the work status of the 59 adult male patients included in this study is represented in figure 3, which indicates that 9 of the 30 patients who were not working at the start of therapy returned to work some time during the course of treatment with prednisone The 29 patients who were working maintained this status, although several of these experienced short periods of unemployment resulting from temporary flares of rheumatoid activity.

Undesirable Effects of Therapy

Nearly all of our patients receiving prednisone exhibited some manifestations of adrenal cortical hyperfunction (Cushing's syndrome), such as moon facies, buffalo obesity, increased appetite, insomnia, striae, and ecchymoses. The severity of these signs was generally proportional to dosage of prednisone and/or duration of therapy. In general, these manifestations were tolerated by the patient as a nuisance of relative unimportance. Edema and elevation of blood pressure were notably rare. This was in contrast to our previous experience with equivalent doses of hydrocortisone, when water retention was evident in the majority of instances.

The most disturbing side-effects noted were those referable to the digestive tract. Dyspepsia, referring to indigestion, heartburn, epigastric distress, or sour eructations (symptoms simulating those of peptic ulcer), occurred in 25% of our patients before prednisone therapy. After the institution of therapy, 48% exhibited dyspepsia of some degree. Considering only those patients with moderate to severe dyspepsia, it was again demonstrated that under therapy a twofold increase developed in the number of patients with this degree of gastrointestinal difficulty (11% before; 21% during therapy).

X-rays of the upper gastrointestinal tract were obtained in 43 patients who exhibited severe or persistent dyspepsia during treatment. Findings in 32 of these were normal. In three cases a diagnosis of hypertrophic gastritis was made, but no evidence of ulceration was noted. In one patient a scarred duodenal cap, without an ulcer niche, was demonstrated.

In four patients, two of whom were male, duodenal ulcers were seen. In one of these an x-ray of the gastrointestinal tract made prior to therapy had been normal. All four developed disturbing dyspepsia after administration of the steroid, in a dosage ranging from 10 to 20 mg. per day, for a period of 4 to 10 months.

Three female patients were noted to have a gastric ulcer on gastrointestinal x-rays made three to four months after prednisone therapy was begun and while they were receiving a dosage ranging from 6 to 10 mg. per day. In one of the three an x-ray of the gastrointestinal tract made prior to therapy had been normal. All three had mild dyspepsia prior to therapy, and in two of the three the distress increased markedly with the addition of prednisone.

Five patients developed complications of peptic ulcer. Three of these, who were taking from 10 to 25 mg. of prednisone per day, developed hemorrhage; in the other two the ulcers perforated. One patient with a history of gastrointestinal bleeding four years previously while on phenylbutazone therapy, who failed to adhere to a prescribed ulcer regimen, developed gastric hemorrhage during the third month of prednisone therapy. The second patient, a woman with severe rheumatoid arthritis who was obese, hypertensive, and plethoric, and who had been on corticotropin or hydrocortisone medication for years, died from gastrointestinal hemorrhage during the seventh month of therapy. The third patient, who developed a bleeding ulcer during the second month of treatment, required a subtotal gastric resection. Two patients, receiving 10 and 15 mg. of prednisone per day, respectively, developed perforations of duodenal ulcers 3 months and 12 months after the institution of therapy. These were successfully repaired surgically. In one of these patients x-rays of the gastrointestinal tract made prior to therapy had been normal.

	WORKED DURING PREDNISONE THERAPY		
WORKED BEFORE PREDNISONE	NO	YES	TOTAL
NO	21	9	30
YES	0	29	29
TOTAL	21	38	59

Fig. 3.—Gainful employment status of 59 male patients.

Despite evidences of peptic ulceration, in 11 of the 12 patients described above it became necessary to resume prednisone therapy. This was combined with a strict ulcer regimen and was well tolerated. In addition, there were two patients with a diagnosis of peptic ulcer made many years before in whom prednisone therapy was instituted, combined with an ulcer program. Two other patients, one of whom had been receiving cortisone, exhibited gastric ulcer on x-rays of the upper gastrointestinal tract made prior to the institution of prednisone therapy. Gastric resection was performed in one of these cases before institution of therapy.

Effect on Gastric Secretion

Impressed with the relatively high incidence of dyspepsia, we undertook a study in which gastric analyses (with use of Ewald's test meal), including pH and free and total acid measurements, were performed on 6 rheumatoid arthritics before and after prednisone therapy and on 10 rheumatoid patients after institution of therapy with prednisone.

In five of the six cases studied, there was an increase in free and total acidity, with a drop in pH values. Although statistically significant, this increase was not to values as high as those usually observed in patients with ulcer. Moreover, even though prednisone increased gastric acidity in most cases, there was no consistent correlation between this increased acidity and the presence of peptic ulcer. The latter was associated in some instances with a normal range of free hydrochloric acid or with relatively slight increases. The experience of Kammerer and Rivelis[6] was quite similar to our own.

Effect on Glucose Tolerance

In three patients previously aglycosuric, marked glycosuria and hyperglycemia developed. Two of these patients require insulin at present. In six other patients in whom either decreased glucose tolerance or overt glycosuria and hyperglycemia were present prior to therapy, the administration of prednisone was followed by the appearance of glycosuria or an increase in the insulin requirement.

Two patients developed fractures while on prednisone therapy. In one patient a fractured femur appeared after severe trauma. In the other, a severe degree of osteoporosis, present for many years, possibly contributed to the fracture which developed after mild trauma. The latter patient had been receiving steroids for years prior to the institution of prednisone therapy and had had a prolonged period of immobilization in bed prior to ambulation with crutches.

Deaths

In the entire group of 156 patients, there were 3 deaths. One patient died of bile duct cancer, another of generalized vasculitis with involvement of the mesenteric vessels and perforation of the colon, and the third from a bleeding peptic ulcer.

Comment

Our present evaluation of the effect of prednisone in rheumatoid arthritis confirms our earlier impressions regarding its effectiveness in lessening the activity of this disease, thereby improving the functional capacity of the individual. If it is remembered that the majority of our patients had relatively far advanced, severe forms of the disease, and that most of them had been receiving hydrocortisone ineffectually prior to substitution of prednisone, then the restoration and maintenance of some degree of functional integrity of the individual for periods of 4 to 14 months represents an impressive accomplishment. Fifty-seven per cent of the patients had a measurable decrease in total severity of the disease. Forty-one per cent had measurable improvement in functional capacity, and 9 out of 30 male patients who were not working returned to work through the effect of prednisone.

With wider experience and with increasing effort to ward off undesirable effects of the steroid, we found it expedient to reduce the dosage of prednisone in the majority of patients to a maintenance level of 10 mg. per day or less. To be sure, the fullest degree of functional restoration was not achieved, but, with less exposure to hypercortisonism, the long-continued administration of the steroid demanded by the chronicity of this disease may be facilitated.

Minor side-effects noted in the majority of patients were not disturbing. Most patients with salt and water retention resulting from hydrocortisone lost the edema or the degree of fluid retention decreased markedly when prednisone was substituted, with actual improvement in functional capacity of the individual. The rare instances of fluid retention during prednisone therapy could be readily controlled by restriction of salt in the diet.[2b]

Gastrointestinal complications constituted the most disturbing undesirable effects of therapy. Since pretreatment gastrointestinal x-rays were not obtained routinely, we are unable to draw conclusions concerning the development of peptic ulcer with prednisone. Peptic ulcer was demonstrated, however, during treatment with prednisone in 7 of 43 patients in whom gastrointestinal x-rays were obtained because of the severity of symptoms. Gastric hemorrhage or perforation of an ulcer developed in five additional cases.

It is of practical interest that in all of our patients who developed dyspepsia while on prednisone therapy, and in the four patients with a history of previous ulcer, administration of an aluminum hydroxide gel preparation and a diet incorporated in an ulcer regimen, generally combined with some reduction in the dosage of prednisone, appeared to relieve digestive symptoms.

A similar program of dietary and antacid medication permitted the continuation of prednisone medication, which was indispensable in all four patients with duodenal ulcer, in the three female patients with gastric ulcer, in two of the three patients who had bleeding peptic ulcers and in the two patients who had perforation of their ulcers. Without the steroid three of these patients were bedridden and unable to care for any of their most basic needs. With reinstitution of prednisone therapy in a dosage of 15, 10, and 5 mg. daily, respectively, one patient became ambulatory, the other could get around with the aid of crutches, and the third maintains a wheelchair existence. In all such cases, the absolute necessity for reinstituting prednisone therapy seemed to justify the potential risk involved. On this regimen the patients were not only free of dyspepsia but the gastrointestinal x-rays became normal and have remained so. This suggests that, when it is absolutely essential, prednisone therapy may be continued with some reduction in dosage, but definitely with a strict ulcer regimen.

The appearance of glycosuria or an increase in severity of existing diabetes was noted in nine of our patients. In general, adherence to a diabetic regimen, or reduction in the dosage of prednisone, managed the situation.

Conclusions

As evaluated in a series of 156 patients with rheumatoid arthritis, prednisone appeared to be an effective agent in suppressing rheumatoid activity and in improving the functional capacity of the individual. In general, side-effects of therapy were not disturbing. However, disturbing gastrointestinal symptoms and signs did appear. Definite peptic ulcer was noted in 7 of 43 patients with dyspepsia in whom gastrointestinal x-rays were made because of digestive distress. In five additional patients either gastric hemorrhage or perforation of an ulcer developed.

When absolutely essential for maintenance of the patient's functional capacity or his self-sufficiency, it may be possible to continue administration of prednisone even in the face of peptic ulcer, if a strict ulcer regimen, including diet, antacids, and antispasmodics, is administered concomitantly. In the final analysis, evaluation of any given therapeutic program in rheumatoid arthritis requires individualization of therapy and follow-up of patients over a period of many years.

The enforced resort to steroids for the management of rheumatoid arthritis, despite the occurrence of side-effects, including peptic ulcer with its inherently serious complications, emphasizes the urgency for the development of more effective agents for patients in whom nothing else provides adequate improvement of disability.

500 Penn Ave. (22) (Dr. Stolzer).

This study was aided by a grant from the Anne L. and George H. Clapp Charitable and Educational Trust to the Western Pennsylvania Chapter of the Arthritis and Rheumatism Foundation.

The prednisone and prednisolone used in this study were supplied as Meticorten and Meticortelone by the Schering Corporation, Bloomfield, N. J., and as Deltra and Hydeltra by the Sharp & Dohme Corporation, Philadelphia.

Priestley in the United States.—The home of Joseph Priestley has been acquired and is being restored to its original appearance by the Borough of Northumberland, Pennsylvania, U. S. A. This house, started in 1795 and completed in 1797, and owned for many years by the Priestley family, was purchased in 1920 by the Pennsylvania State University and presented this year (1956) to Northumberland. The home is of Georgian architecture, is in fine condition, and occupies an acre of landscaped ground near the Susquehanna River. Under the direction of the Priestley Memorial Association, the widow's walk, kitchen and laboratory are being restored to their original apearance and the rooms refurnished with American furniture of about 1800. The Association desires to gather all obtainable information on Priestley and on his American home. It would like to receive reprints of articles bearing on his work, and it welcomes correspondence with anyone interested in this matter; visitors are welcome. Correspondents should write to Mr. Lewis K. Rich, 464 Front Street, Northumberland, Pennsylvania. The Division of History of Chemistry of the American Chemical Society is cooperating with the Priestley Memorial Association in the restoration of Priestley's laboratory. To this end a committee including Sidney Edelstein, Claude K. Deischer and Wyndham Miles (chairman) has been constituted. The committee wishes to locate apparatus of Priestley's American period, with the view of acquiring them or having replicas made. It welcomes correspondence with anyone knowing the whereabouts of apparatus, and with scholars interested in this project; correspondence should be addressed to Dr. Wyndham Miles, Edgewood, Maryland.—News and Views, *Nature*, Nov. 24, 1956.

J.A.M.A., Sept. 7, 1957

ZOXAZOLAMINE AND/OR CHLORPROMAZINE FOR MUSCLE SPASM

James W. Gibson, M.D., Seymour S. Bluestone, M.D.
and
Edward W. Lowman, M.D., New York

Eight patients who had skeletal muscle spasticities due to spinal cord injuries received various combinations of four drugs, (1) zoxazolamine, (2) a placebo resembling zoxazolamine, (3) chlorpromazine, and (4) a placebo resembling chlorpromazine. Each patient's status with respect to muscular spasticities was evaluated objectively by observers who, like the patient himself, did not know which combination of drugs he was receiving at a given time. The dosages used were 500 to 1,000 mg. of zoxazolamine and 25 to 50 mg. of chlorpromazine, all given four times a day, and were sufficient to cause some side-effects (drowsiness, nausea) in six of the eight patients. These dosages did not, however, have any consistent effect on muscular spasticity in this series of patients.

It is well recognized that involuntary muscle spasm is one of the most disturbing sequelae in cases of injuries of the spinal cord which have produced transverse myelopathy. At the Institute of Physical Medicine and Rehabilitation of the New York University-Bellevue Medical Center, spasticity has been found to be the major deterrent to the physical rehabilitation of a large number of quadriplegics and paraplegics.

Cooper [1] has pointed out the great usefulness of subarachnoid alcohol block for the relief of spasticity in paraplegia. Like other destructive neurosurgical procedures for eliminating spasm, this is irreversible. For this reason, a drug which would relieve spasticity without jeopardizing return of motor function would be of inestimable value.

Recently, zoxazolamine (Flexin) has been shown to produce a flaccid paralysis of the limb musculature of animals.[2] Chlorpromazine (Thorazine) hydrochloride is said to act as a skeletal muscle relaxant.[3] Amols [4] states that zoxazolamine is a mild muscle relaxant for spastic conditions and that this effect is markedly increased by combination with chlorpromazine. He found that this combination of zoxazolamine with small doses of chlorpromazine afforded the best therapy as a centrally active muscle relaxant. Smith and associates [5] found zoxazolamine to be 85% effective in relieving muscle spasm in rheumatoid disease where the major disability was due to stiffness and aching. Abrahamsen and Baird [6] administered zoxazolamine to 28 children with the spastic form of cerebral palsy and in every instance found a decrease of muscle tone on passive flexion. Rodríquez-Gómez and associates [7] in a similar study found that 14 of 18 patients with spasticity resulting from injuries of the spinal cord showed objective relief of spasticity.

Method of Study

In view of the encouraging reports cited above, a clinical evaluation of these drugs was initiated at the Institute of Physical Medicine and Rehabilitation. In a double-blind study, patients with spasm ranging from moderate to severe were given zoxazolamine or zoxazolamine placebo and chlorpromazine or chlorpromazine placebo in different combinations and dosages. The drugs were ordered by code and at no time did any of the reporting personnel know the drug combinations the patients were receiving. We felt that the only practical means of evaluating the merit of an antispasm medication was to assess clinically both its subjective and its objective effect on the patient. Daily reports (table 1) were submitted by the patient, his resident physician, his nurse, his full-time or part-time attendant, physical therapists, occupational therapists, and instructors in activities of daily living. Personnel were assigned to each patient on a permanent basis for the duration of the study.

Report of Cases

Eight patients were included in the study regarding the effect of zoxazolamine and/or chlorpromazine in ameliorating skeletal muscle spasticity due to spinal cord injuries.

Case 1.—This 22-year-old male student suffered a vertebral fracture dislocation of T-10 and T-11 in an automobile accident on May 13, 1954. At laminectomy the spinal cord was found to be three-quarters transected. The patient was admitted to the

Institute of Physical Medicine and Rehabilitation on Jan. 3, 1956, and was found to have complete motor and sensory loss below the level of the 10th thoracic dermatome. There was moderate spasticity of both lower extremities which interfered with ambulation in braces.

TABLE 2.—*Drugs and Dosage (Case 1)**

Date 1956		Side-Effects
5/17	500 mg. zoxazolamine placebo 25 mg. chlorpromazine	
5/23	500 mg. zoxazolamine 25 mg. chlorpromazine	Dizzy, drowsy
5/31	1,000 mg. zoxazolamine 25 mg. chlorpromazine	Dizzy, drowsy
6/ 4	500 mg. zoxazolamine placebo 25 mg. chlorpromazine	"Feels better"
6/ 6	1,000 mg. zoxazolamine placebo 25 mg. chlorpromazine placebo	
6/12	500 mg. zoxazolamine placebo	
6/24	Home	

* No decrease in spasm; all drugs given 4 times a day.

CASE 2.—This 33-year-old man sustained a vertebral fracture-dislocation in an automobile accident on Jan. 28, 1955. He was admitted to the Institute of Physical Medicine and Rehabilitation on March 24, 1955, with severe spasticity of all four extremities which virtually prohibited all efforts at rehabilitation.

TABLE 3.—*Drugs and Dosage (Case 2)**

Date 1956		Side-Effects
5/17	500 mg. zoxazolamine 25 mg. chlorpromazine	
5/23	1,000 mg. zoxazolamine placebo 50 mg. chlorpromazine	
5/31	1,000 mg. zoxazolamine 50 mg. chlorpromazine	
6/ 1	1,000 mg. zoxazolamine	Drowsy, heart burn, malaise, "out of sorts"
6/ 4	50 mg. chlorpromazine	
6/ 5	750 mg. zoxazolamine placebo 50 mg. chlorpromazine	Drowsy
6/ 6	50 mg. chlorpromazine placebo	Bright
6/11	50 mg. chlorpromazine placebo	Weak, tired
6/12	750 mg. zoxazolamine 50 mg. chlorpromazine placebo	Nauseated
6/13	750 mg. zoxazolamine	Still nauseated
6/14	50 mg. chlorpromazine placebo	
6/15	Cut all drugs	No nausea
6/18	Off study	
6/28	Intrathecal alcohol wash done, with relief of spasms in torso and lower extremities	

* No decrease in spasm; all drugs given 4 times a day.

CASE 3.—This 44-year-old man had pain in his back on Aug. 10, 1953, followed by paraplegia at a level of the 10th thoracic vertebra. Laminectomy revealed a large epidural abscess which was evacuated. There then developed muscle spasm below the level of the injury of such severity as to produce dislocation of the right hip. The following surgical procedures were subsequently performed for relief of pain and spasm: (1) Jan. 6, 1954, bilateral obturator neurectomy; (2) Nov. 30, 1954, right femoral nerve crush and partial section of right psoas; (3) Dec. 9, 1954, sectioning of the anterior and posterior roots of T-10 and T-11 and of the anterior roots of T-12 and L-1 and L-2; (4) Feb. 1, 1956, anterior rhizotomy from L-2 to L-5; (5) March 30, 1956, spinothalamic tractotomy; (6) April 16, 1956, posterior rhizotomy from T-9 to L-2, right. Despite these multiple surgical procedures, when the patient was admitted to the Institute of Physical Medicine and Rehabilitation on May 1, 1956, severe spasm in both lower extremities continued to impede rehabilitation.

CASE 4.—This 40-year-old man sustained a spinal cord injury in an automobile accident July 19, 1954, with resultant quadriplegia at the level of the fifth cervical vertebra. He was admitted to the Institute of Physical Medicine and Rehabilitation on March 16, 1956, and spasms were found to be severe in all four extremities and trunk. There was normal range of motion on those occasions when the spasm could be broken through. Spasticity was so severe as to preclude attempts at rehabilitation.

7/24	Home—refused alcohol wash	

* No decrease in spasm; all drugs given 4 times a day.

CASE 6.—This 45-year-old steel-foundry worker experienced the sudden onset of severe interscapular pain on Oct. 8, 1955, followed shortly by quadriplegia. Laminectomy disclosed a protruded intervertebral disk compressing the spinal cord between C-7 and T-1. Spasticity was marked in the trunk and both lower extremities upon admission to the Institute of Physical Medicine and Rehabilitation on April 10, 1956. It was impossible for therapists to overcome the spasm.

CASE 8.—This 41-year-old woman sustained a right hemiplegia in March, 1953. For many years prior to this, she had been hypertensive. At the time of her admission to the Institute of Physical Medicine and Rehabilitation on April 30, 1956, there was severe spasm in the right upper and lower extremities which markedly limited rehabilitation efforts.

Summary and Conclusions

A clinical study, in which the double-blind method was used, was conducted to evaluate the effectiveness of zoxazolamine, zoxazolamine placebo, chlorpromazine, and chlorpromazine placebo in various combinations and dosages for the relief of spasticity. Among eight patients studied (six quadriplegics and paraplegics, one multiple sclerotic, and one hemiplegic as a result of a cerebrovascular accident), only the patient with multiple sclerosis benefited (table 10) from the administration of zoxazolamine and chlorpromazine. The results reported here indicate that zoxazolamine and/or chlorpromazine are not effective in ameliorating skeletal muscle spasticity due to spinal cord injuries.

400 E. 34th St. (16).

SEGAL'S TUBELESS GASTRIC ANALYSIS WITH AZURE A RESIN COMPOUND

A SIMPLE PROCEDURE FOR SCREENING INDIVIDUALS WITH ACHLORHYDRIA IN A GASTRIC CANCER DETECTION PROGRAM

Vance Fentress, M.D.
and
David J. Sandweiss, M.D., Detroit

Patients with achlorhydria and hypochlorhydria show a much greater disposition to gastric cancer. Further, the early detection of pernicious anemia presents a problem because of the plethora of proprietary hematinics. As an aid to cancer detection, the tubeless method of determining free hydrochloric acid in the stomach removes many of the previous inconveniences which have discouraged widespread use of this screening test. However, pyloric obstruction, impairment of small intestinal absorption, hepatic disease, and impairment of renal function may interfere with the accuracy of the test.

Patients with achlorhydria, the so-called gastric cancer precursor group,[1] can be identified with a high degree of reliability by the simple method of tubeless gastric analysis devised by Segal and co-workers,[2] using orally administered azure A resin compound. This compound, ingested orally, colors the urine blue or blue-green if free hydrochloric acid is present in the stomach at the time of the test. We have found that, of 100 subjects who had been demonstrated by one or more intubation procedures to have achlorhydria, 95 showed anacidity by this simple tubeless method and that, of the 34 patients with proved pernicious anemia in this group, all showed anacidity by the tubeless technique. The significance of this finding is that this tubeless method of gastric analysis offers a simple procedure for screening persons with achlorhydria in cancer-detection centers, hospitals, outpatient departments, and doctors' offices. Once achlorhydria is detected, one may then institute periodically such other well-known examinations for the diagnosis of early asymptomatic gastric cancer as x-ray, gastroscopy, and cytology, which are not now practicable for use on a wide-spread, routine basis in the general population.

The azure A resin compound consists of a highly purified carboxylic acid cation-exchange resin (Amberlite XE-96), in which a specific number of hydrogen cations have been replaced by azure A dye cations. In the presence of dilute hydrochloric acid, the process is reversed and the azure A cations are displaced by the hydrogen cations of the free hydrochloric acid. A significant quantity of azure A is displaced in hydrochloric acid solutions with a pH lower than 3, with maximum displacement at a pH of 1.5.[2] The azure A dye, so released, is then absorbed in the small intestine and excreted in the urine, coloring it blue or blue-green.

The azure A resin compound was first introduced by Segal, Miller, and Plumb, in 1955,[3] as an improvement over the tubeless method of gastric analysis with quinine carbacrylic resin, which Segal and his associates employed previously.[4] Similar encouraging results were then reported by us [5] and by McGowan and Stanley,[6] Galambos and Kirsner,[7] Sievers and Gieselman,[8] and Bolt.[9] Our present study deals with the series of 100 subjects with achlorhydria referred to above.

Method

After at least an eight-hour fast, the patient swallowed a Levin tube, and a fasting gastric aspiration was obtained. Three hundred cubic centimeters of 5% alcohol was then administered into the stomach via the Levin tube, and gastric specimens were obtained at 15-minute intervals for a period of one hour. Each specimen was titrated for free and total acid by the usual routine method, with use of Töpfer's reagent and phenolphthalein as indicators. If free hydrochloric acid was absent, 1 mg. of histamine phosphate was injected subcutaneously, and two additional specimens were aspirated 15 and 30 minutes after the injection of histamine. These specimens were similarly titrated for free and total acid. Thirty minutes after the administration of histamine the Levin tube was removed without aspirating the stomach completely. The patient then voided, and this specimen was identified as the control urine. The patient was then given 2 Gm. of azure A resin compound orally with 150 cc. of water. At times an additional 50 to 75 cc. of water was allowed, to assure the ingestion of all of the insoluble azure A compound. Two hours later, the patient voided again and this specimen was identified as the test urine. This procedure was followed for 79 of the 100 subjects. These 79 patients included 31 with pernicious anemia.

The remaining 21 subjects comprised patients who were known to have achlorhydria by previous intubation studies. Only three in this group were patients with pernicious anemia. These 21 patients were not

---

From the Department of Internal Medicine, Harper Hospital.

subjected again to a gastric analysis by intubation on the morning of the azure A test. These patients reported with empty stomachs, and, after voiding the control urine, they were given 1 mg. of histamine phosphate subcutaneously. Immediately thereafter, the azure A resin compound was administered as described above; the test urine was collected two hours later.

Two standard solutions of azure A were employed for color comparison, those containing 0.3 and 0.6 mg. The former was prepared by the addition of 0.3 mg. of azure A dye to 300 cc. of distilled water and the latter by the addition of 0.6 mg. of the dye to 300 cc. of distilled water. Aliquots of 10 cc. of the respective standard solutions were then poured into test tubes, and these two standard solutions were used for color comparison.

The control and the test urine specimens of each subject were diluted with water to a volume of 300 cc. Aliquots of 10 cc. of each diluted urine specimen were poured into test tubes, and each specimen was acidified with 1 drop of 18% hydrochloric acid. The test tubes were then heated in a bath of boiling water for a period of 10 minutes, after which they were allowed to cool slowly to room temperature. The color of the two urine specimens were then compared with the colors of the two standard azure A solutions.

Results of Azure A Tests in 100 Patients Found by Intubation Technique to Have Achlorhydria

	Patients, Total No.	Negative*	Borderline Positive†	Positive‡	Correlation of Two Tests, %
Patients with pernicious anemia.......	34	34	...	...	100
Patients without pernicious anemia.......	66	61	3	2	92
Total	100	95	3	2	95

* No change in color or color less than 0.3-mg. standard solution of azure A.

† Color equal to or more intense than 0.3-mg. standard but less intense than 0.6-mg. standard solution.

‡ Color equal to or more intense than 0.6-mg. standard solution.

It might be added that the 100 subjects in this series comprise a selected group of patients—selected, in that they failed to show free hydrochloric acid during one or several intubation tests. We concentrated on subjects with achlorhydria, because we were particularly interested in determining whether the azure A resin compound test is sufficiently accurate to warrant its use in the screening of subjects with achlorhydria, in whom the incidence of gastric cancer is high.

We excluded from this study patients known to have pyloric obstruction, impairment of small intestinal absorption, hepatic disease, or impairment of renal function and patients with urinary retention, since these conditions might interfere with the accuracy of the azure A test.

Interpretation of Results

In interpretation of the results, if the test urine specimen developed a blue color equal to or more intense than that of the 0.6-mg. standard solution, the test was interpreted as positive, i.e., as showing that the subje has secreted free gastric hydrochloric acid. If the te urine specimen developed a blue color ranging in i tensity from that of the 0.3-mg. standard to less tha that of the 0.6-mg. standard, the test was interprete as positive, but borderline, i.e., as showing that th subject did secrete free gastric hydrochloric acid b that it was probably of low hydrochloric acid conce tration. If the test urine specimen failed to develop blue color or developed a bluish color of less inte sity than that of the 0.3-mg. standard, the test was i terpreted as negative, i. e., as showing that the patie did not secrete free hydrochloric acid at the time of t azure A test. These interpretations were employed b us in our previous study of 114 patients, in each whom both the intubation method of gastric analys and the tubeless azure A method were employed du ing the same morning.[5] We found 95% accuracy wi the tubeless method, when the results were compar with those of the intubation technique.

Results

Details of the results are given in the table. It w be noted that the azure A test was negative in each the 34 patients with pernicious anemia, a correlati of 100%. Of the 66 patients without pernicious anem who were found to have achlorhydria on one or mo intubation tests, 61 showed negative azure A tests, correlation of 92%. Three patients showed positive b borderline tests, and two showed definitely positi azure A tests. In three of these five patients both t intubation and tubeless tests were repeated with si ilar discrepancy in the results. Of the 5 patients whose specimens free hydrochloric acid was shown be present on azure A tests, 3 were among the 79 whom the two tests were performed during the sam morning (4% failure of correlation) and 2 were amo the 21 on whom the two tests were performed durin different days (10% failure of correlation). Of the tot series of 100 subjects whose specimens failed to sho free hydrochloric acid when tested by the intubatio technique, 95 failed to show hydrochloric acid secr tion on the azure A test, giving an over-all correlati of 95%.

Comment

The 34 patients with proved pernicious anemia de nitely had true achlorhydria. In this group of patien the azure A tests were all negative, a correlation 100%. It is unlikely, however, that the 66 patients wit out pernicious anemia all had achlorhydria, since it well known that failure to find free hydrochloric ac in one or two series of fractional gastric analyses do not necessarily prove true achlorhydria, even thou effective doses of histamine are used. This might e plain the positive results on the azure A test in five the patients. These five patients might well be fou to be acid secretors on repeated intubation tests, was the case with several patients not included in this series. Consideration should also be given to a possible displacement of the azure A cations by hydrogen cations of the acid contents of the small intestine; this might account for an occasional positive azure A test among patients who have true gastric achlorhydria. This might also explain the voiding of blue-colored urine for a day or two after the azure A test, which occurred even among some of our patients with pernicious anemia.

As stated above, the 66 subjects without pernicious anemia. although they failed to show free hydrochloric acid on one or two intubation tests, do not necessarily have true achlorhydria. The same can be said for those whose specimens failed to show hydrochloric acid on the azure A test. In fact, we question whether the azure A test can be depended upon for a diagnosis of true achlorhydria, especially since the azure A cations are displaced by the hydrogen cations at a pH of only 3.[2] To prove true achlorhydria, patients would have to be subjected to repeated intubation studies, employing also other gastric secretory stimulants besides alcohol and histamine.[10] Also, it would be essential to determine the pH values for each of the gastric specimens studied.[10a] No doubt a number of these 66 subjects would be found to be acid secretors if such procedures were employed. We did not consider such a program essential for the present study, however, because we were interested primarily in determining the degree of correlation between the azure A test and the intubation test, which is generally in use, and in determining whether the azure A test is sufficiently accurate to warrant its use in a gastric cancer detection program in the screening of patients with both achlorhydria and hypochlorhydria, since each group has a greater disposition to gastric cancer. If it is assumed, as we believe that it can be assumed, that most of these 66 subjects who were shown to have achlorhydria by intubation tests have either achlorhydria or hypochlorhydria, then, indeed the 61 individuals with negative results and the 3 with borderline results on the azure A test are those who should be screened for subsequent careful and thorough study.

The greater disposition of patients with achlorhydia and hypochlorhydria to gastric cancer is well known. Recently Hitchcock and co-workers [1] reported that the incidence of gastric cancer in this group is 5.2 times higher than would be expected in a similar age group in the general population. These authors employed the intubation method of gastric analysis, employing histamine as the gastric secretory stimulant. The even greater disposition of patients with pernicious anemia to gastric cancer is also well known. The same authors reported that, in patients with pernicious anemia, the incidence was 18.3 times higher. Other studies indicate that gastric cancer is found once in each 100 patients with gastric anacidity; in patients with pernicious anemia, the incidence of gastric cancer may be as high as 3 to 5 per 100 patients examined.[11] Depending on the sample selected. Zamcheck and coworkers [12] found that the frequency of gastric cancer among patients with pernicious anemia varied from less than 1% to more than 11%. It might be added that the early detection of pernicious anemia also presents a problem nowadays because of the plethora of proprietary hematinics, which mask many cases of pernicious anemia.

The great inconvenience of and the time required by the intubation method of gastric analysis have discouraged the test's widespread use as a screening device for identifying patients with achlorhydria. With the tubeless method, these deterrents are absent. The following conditions, however, may interfere with the accuracy of the azure A test: pyloric obstruction, impairment of small intestinal absorption, hepatic disease, and impairment of renal function.

Of course, it is well known that gastric cancer occurs also among individuals with normal values of free gastric hydrochloric acid. We are of the opinion, however, that an aggressive program of cancer detection among persons with achlorhydria and hypochlorhydria, in whom the incidence of gastric cancer is high, would certainly be a step in the right direction. As a first step in this program, it is recommended that the azure A tubeless method of gastric analysis be instituted as a routine screening procedure in cancer-detection centers, hospitals, outpatient departments, and physicians' offices. Once achlorhydria or hypochlorhydria is detected, the patients may then be subjected regularly to the other well-known examinations for the detection of early asymptomatic gastric cancer, such as x-ray, gastroscopy, and cytology. Such a program is now in operation in the outpatient department at Harper Hospital, Detroit, for all patients 40 years of age and older.

Summary

One hundred subjects found to have achlorhydria by the intubation method of gastric analysis were subjected to Segal's tubeless method of gastric analysis, with use of the orally administered azure A resin compound, which colors the urine blue or blue-green when free hydrochloric acid is present in the stomach. Alcohol and histamine phosphate were used as the gastric secretory stimulants. Thirty-four of the subjects were patients with proved pernicious anemia. Seventy-nine of the patients were subjected to the two tests during the same morning and 21 patients on different mornings.

Of the 34 patients with pernicious anemia, all showed negative results on the azure A test—a correlation of 100%. Of the 66 subjects without pernicious anemia, 61 showed negative results on the azure A test— a correlation of 92%. Three patients showed positive but borderline results, and two patients had definitely positive results. Of the 5 patients who failed to show correlation between the two tests, 3 were among the 79 patients on whom the two tests were performed during the same morning (4% failure of correlation) and 2 were among the 21 patients on whom the two tests were performed on different days (10% failure of correlation). Of the total 100 subjects, 95 showed negative results on the azure A test—an over-all correlation of 95%.

Our data indicate that Segal's tubeless method of gastric analysis with azure A resin is sufficiently accurate to warrant its use in screening patients for achlorhydria and hypochlorhydria, in whom the incidence of gastric cancer is known to be high. Once these conditions are detected, the other well-known examinations for the detection of early asymptomatic gastric cancer, such as x-ray, gastroscopy, and cytology, which are not now practicable for use on a widespread routine basis in the general population, may then be instituted and used periodically.

15201 W. McNichols Rd. (35) (Dr. Sandweiss).

The azure A resin compound used in this study was supplied by E. R. Squibb and Sons, New York.

SOLOX INTOXICATION

William J. Hammack, M.D., Birmingham, Ala.

Solox is the trade name for a shellac and paint solvent consisting primarily of ethyl alcohol and methanol. The clinical picture of Solox intoxication, by ingestion, is coma, a foul chemical odor to the breath (similar to wood alcohol with a superimposed, sweetish, acetone-like overtone), acidosis, and, of particular importance, hypoglycemia. There is a peculiar extensor rigidity of the extremities, apparently correlated with the hypoglycemia. Therapy is usually toward correcting the acidosis, alleviating the hypoglycemia, preventing complications, and giving supportive care. Recovery is complete if death does not intervene.

Severe hypoglycemia from any cause is a grave medical emergency because of the rapidity with which irreversible cerebral damage or death may ensue. It is, thus, of the utmost importance to diagnose and treat this condition correctly and rapidly. Solox "smoke" intoxication is a relatively common cause for profound hypoglycemia, but the condition frequently appears under circumstances tending to obviate the recognition of that hypoglycemia. Solox is the trade name for a shellac solvent made according to the following formula: pure ethyl alcohol, 100 gal.; denatured grade wood alcohol, 5 gal.; gasoline, 1 gal.; ethyl acetate, undenatured, 1 gal.; methyl isobutyl ketone, 1 gal. Brown and Harvey[1] in 1941 reported six patients who were brought to Johns Hopkins Hospital in hypo-

---

From the Department of Medicine, University of Alabama Medical College, and Medical Service, Veterans Administration Hospital.

glycemic coma after drinking what was believed to be a liquid paint remover. Tucker and Porter[2] reported four similar cases in 1942 and stated, "It is well known that a preparation sold under the name of 'Solox' is widely used in the Richmond (Va.) area as a beverage." Bennett[3] has observed Solox intoxication to be a frequent occurrence in the southern states.

The exact number of patients brought to a hospital with Solox intoxication cannot be obtained. A history is usually not available, and the frequent emergency treatment of alcoholism with intravenous injection of hypertonic dextrose solution may alleviate the hypoglycemia. Because this disorder is not widely recognized, most of these individuals are treated only in the emergency wards and are never admitted to the hospital.

Selection of Patients

This study consists of patients seen in the admission rooms or admitted to the wards of both the University Hospital and the Veterans Administration Hospital, Birmingham, Ala., from 1946 to 1956. Thirty-six patients either gave a history of drinking Solox or presented a clinical picture typical enough to be diagnosed as such. All but four of these were Negroes, and the majority had been chronic alcoholics for several years. The purpose of this paper is to present and discuss the effects of Solox intoxication in these patients and to emphasize the hypoglycemia which is frequently present. Severe acidosis, methanol poisoning, or hypoglycemia necessitated hospitalization of many of these patients, and death was a frequent occurrence. It was considered likely that 15 other patients had consumed this mixture, but the data were not conclusive enough to merit their inclusion in this series. The figure presents certain clinical and laboratory findings of these patients.

Clinical Picture

An immediate history is seldom obtained from these patients because they are usually comatose. History obtained subsequently from relatives or friends reveals that chronic alcoholism has usually been present, with a degree of malnutrition and starvation compatible with the extent of the alcoholic debauch. Solox intoxication and acute ethanol intoxication are so similar that very few patients are brought to the attention of physicians unless coma or other complications occur which necessitate emergency care. Occasionally, when the patient is conscious, he may complain of blurred vision, intense cramping abdominal pain, and burning of the eyes. The abdominal pain is often relieved by intravenously administered hypertonic dextrose solution. The odor of the breath is characteristic, but it is difficult to describe. There is a foul, chemical odor, similar to wood alcohol, with a superimposed, sweetish, acetone-like overtone. It is distinctly different from, and should not be confused with, the acetone odor of diabetic acidosis.

Clinical and laboratory findings of 36 patients suffering from Solox intoxication. Blood and cerebrospinal fluid determinations were by method of Folin and Wu. Carbon dioxide-combining power was determined by the method of Van Slyke. DTR=deep tendon reflexes.

On physical examination the blood pressure and pulse are usually normal unless an injury has been sustained. The respirations may be deep and rapid or shallow and depressed, depending on the state of narcosis. Despite laboratory evidence of severe acidosis, some patients have normal respirations, but during recovery a transient period of hyperpnea may develop. The neurological picture is bizarre and changes during the course of the illness. There is often extreme irritability of the central nervous system as manifested by mania and convulsions in the less comatose patients. The pupils are usually widely dilated and fixed; anisocoria may also be present. The importance of the possibility of intracranial injury becomes evident, and this must be excluded by skull films, neurological examination, and careful observation during the intoxicated phase. The gag and cough reflexes are frequently diminished so that aspiration of vomitus occurs. Generalized flaccidity may be observed, with no deep tendon reflexes obtainable; however, this may alternate with extensor rigidity of the extremities if hypoglycemia is present. The response to pain is diminished over the entire body. Pathological reflexes may or may not be present. Bilateral Babinski reflexes have been observed to revert to normal as recovery occurs.

Examination of the lung fields often reveals evidence of pneumonitis. In such instances, numerous rales are heard on auscultation, and they simulate acute pulmonary edema. Digitalization may become necessary as a precautionary measure because acute cardiac decompensation frequently cannot be excluded clinically. This picture is also seen in other hydrocarbon ingestions such as gasoline, kerosene, and petroleum oils. Laboratory evidence of a mild to severe acidosis usually is present, with a carbon dioxide–combining power much lower than the clinical picture would suggest. The blood sugar level may be normal or markedly decreased, with concentrations as low as 13 to 17 mg. per 100 cc. The extensor rigidity of the extremities is apparently correlated with the hypoglycemia. Blood ketones have been observed to be 60 times normal, with blood lactate 8 times normal during the acute intoxication phase. Acetonuria has been present in many of these patients, but never as marked as in diabetes mellitus. Despite the bizarre neurological picture, the cerebrospinal fluid findings are not remarkable; however, no lumbar punctures were made during the hypoglycemic phase.

The course of the illness is variable and depends upon the individual response to the relatively small amount of methanol, and to other complications such as trauma, aspiration of vomitus, and intercurrent disease. Most of these patients are never seen at a hospital and presumably recover without treatment. Death is infrequent in patients who are treated promptly, but chronic mental and physical degeneration may accompany repeated episodes of intoxication.

Pathological Findings

Ten autopsies have been performed at the University hospital on patients believed to have ingested Solox prior to death. Chemical tests, when performed, have demonstrated ethanol and methanol in all tissues, especially the brain, kidneys, and liver. Fatty change of the liver, generalized congestion of all organs, and pulmonary and cerebral edema have been the most frequent findings at autopsy. Three patients have shown pancreatic hemorrhages, but these changes could not be correlated with the hypoglycemic picture, as blood sugar determinations were not done prior to death. The pathological changes represent those found with combined ethanol and methanol intoxication but give no insight into the mechanism of the hypoglycemia.

Treatment

Therapy has usually been directed toward correcting the acidosis, alleviating the hypoglycemia, preventing complications, and giving supportive care. Sodium lactate solution has been used intravenously with success for the acidosis. As a high blood lactate level has been noted during the acute phase, it may be better to use a 2% solution of sodium bicarbonate. Hypertonic dextrose solution given intravenously at 4-to-6-hour intervals for the first 24 hours will usually correct and prevent a recurrence of the hypoglycemia. Patients should be observed carefully for 24 hours after ingestion of Solox because of the frequent recurrence of the hypoglycemia at any time during this period.[4] With prompt diagnosis and treatment, the death rate declines (see figure). Pneumonia has been a frequent complication, and it is advisable to use antibiotics prophylactically and to do a bronchoscopy, if aspiration has occurred. Intravenous therapy with levarterenol or other pressor agents may become necessary, but usually shock is associated only with concurrent injuries.

Comment

Solox intoxication is seen rather frequently in large city hospitals. The clinical picture is so variable that the diagnosis may not be made unless the syndrome is remembered each time a comatose alcoholic is seen. Coma, chemical odor to the breath, hypoglycemia, extensor rigidity of the extremities, unequal deep tendon reflexes, and abnormal reflexes may be seen. As with methyl alcohol, there apparently is a great individual variability of response. All members of a group may drink the same amount, but only a few will develop toxic symptoms. Prolonged usage without any demonstrable ill-effects is very common. Patients have admitted consuming this substance almost each weekend for a period of 10 years without evidence of damage determined by physical examination or laboratory procedures. Although Bennett[5] and Brown and Harvey[1] observed no patients with severe acidosis, patients have been seen in this series with carbon dioxide–combining powers as low as 3.8 mEq. per liter. All of the patients observed with hypoglycemia have been acutely intoxicated in contrast to reports by Tucker and Porter[2] who observed this complication in patients who had slept overnight.

The peculiar extensor rigidity of the extremities is apparently correlated with the hypoglycemia. A similar reaction is often observed in patients with insulin hypoglycemia and hypoglycemia associated with other diseases, such as the "vomiting sickness of Jamaica," which has been reported by Jelliffe and Stuart.[6] The clinical picture of the vomiting sickness is identical to Solox intoxication and is thought to be due to ingestion of toxic wild berries of the genus Blighia sapida. Hypoglycemia, extensor rigidity, coma, convulsions, and death may occur with this syndrome. Recovery is complete if death does not intervene. A liver biopsy performed on one of these patients revealed almost complete absence of liver glycogen. Hassall and others[7] isolated polypeptides from the berries of Blighia sapida and found that these will cause experimental hypoglycemia in animals. The have called these substances hypoglycin A and B. The effect of these compounds on liver glycogen and blood sugar was more than doubled when starvation was present.

The cause of hypoglycemia in Solox intoxication is not known. Intoxication produced experimentally with Solox in normal and starved dogs by Brown and Harvey,[1] and an extensive series of tests on rabbits by Bennett[3] have failed to produce hypoglycemia. The animals were kept comatose for hours, but the result was narcosis only.

There has been no evident hepatic disease to account for the hypoglycemia in the patients in this study. However, in view of the marked glycogen depletion seen in the vomiting sickness of Jamaica, it is obvious that this may be a contributing factor. Malnutrition resulting from the use of alcohol as a food substitute may prepare the liver so that the normal conversion of glycogen to glucose cannot occur as rapidly as is necessary for homeostasis.

Selective poisoning of enzyme systems in the liver is another possibility, although it seems unlikely because of the rapid and complete reversibility of the process. Lesions of the central nervous system have been known to be associated with hypoglycemia, and it is interesting to speculate on a similar irritative effect of Solox. There is nothing clinically or experimentally to substantiate this, however. Evans and co-workers[8] have reported that disruption of sympathetic impulses to the liver of a cat can cause hypoglycemia.

Although occasionally ethanol intoxication alone may be associated with spontaneous "functional" hypoglycemia and hyperventilation syndrome,[9] none of the constituents of Solox do this frequently. Gasoline intoxication may cause tonic muscle spasm, thereby simulating the extensor rigidity. The other constituents either alone or in combination are known to produce cerebral and pulmonary edema, narcosis, coma, and convulsions. Pathologically, these compounds cause fatty change in the liver and kidneys, as well as generalized congestion of all organs.

A majority of the clinical and pathological manifestations are explained by a study of the toxicity of the individual constituents. However, the origin of the frequent and severe hypoglycemia remains obscure. Any of the known causes of hypoglycemia discussed in this paper or possibly unknown homeostatic mechanisms may be involved. The difficulty of study of such patients is obvious, and the rapid treatment necessarily precludes adequate investigation of the hypoglycemia.

Summary

Intoxication with a paint solvent called Solox has been seen frequently in several southern states. A study was carried out of 36 patients with this condition seen at the University Hospital or the Veterans Administration Hospital, Birmingham, Ala. Coma, chemical odor to the breath, acidosis, and hypoglycemia characterize the syndrome. Death may occur as the result of methanol poisoning, respiratory depression, or complications such as aspiration pneumonia. Autopsy findings have been nonspecific. The mechanisms of the hypoglycemia is not understood and most attempts to reproduce hypoglycemia in animals have failed. The syndrome is similar to the "vomiting sickness of Jamaica," in which a toxic hypoglycemia follows ingestion of wild berries.

Addendum

Since the writing of this paper, a patient has been observed with a blood glucose level of 12 mg. per 100 cc. and cerebrospinal fluid sugar level of 10 mg. per 100 cc. This emphasizes the severity of the hypoglycemia to which the central nervous system is subjected.

The formula for Solox was given by U. S. Industrial Chemicals Company, New York City.

HEMATOLOGY—RECORD OF A CENTURY: 1856-1956

William Dameshek, M.D., Boston

One hundred years ago the word anemia was in use, although few measurements of blood had been performed. Purpura and plethora were classified, but there were few, if any, supporting laboratory studies. Blood cells were examined in the fresh state without staining, and blood cell counting was just beginning. Fifty years ago, reduced platelets were described in connection with purpura hemorrhagica, and the blood groups were discovered. A little over a quarter of a century ago, the effects of liver in pernicious anemia opened wide the newer hematology, in which pathophysiology was emphasized. At present we are at the beginning of the era of hematological chemistry. This will undoubtedly lead to expansion in the fields of coagulation disorders, immunohematology, and the hemoglobin abnormalities. The prevention of useless blood loss and the conservation of this most precious fluid for an increasingly healthy society must be the constant aim of the world-wide fraternity of hematologists.

As we meet here in this, the 10th year of our society, and at what I am sure is the largest single world-wide gathering of hematologists ever held, it is well to reflect for a while on hematology as it was, as it is now, and what it might become in the not too distant future. What hematology in all its complexity has become can be seen by a quick glance through our voluminous program, but, lest we feel smug at all our knowledge, let us mention but a few names—leukemia, hemophilia, paroxysmal nocturnal hemoglobinuria (PNH)—and we are immediately aware of how little we actually know of these and other equally mysterious states. Still, the 100 years immediately behind us have witnessed an enormous advance in hematology, certainly as rapid as in other fields of medicine, and perhaps more so than in most.

In 1856, the word *anemia* was in use, although as yet very few actual measurements of the blood had been performed. Just the preceding year, Addison had first used the designation of "idiopathic" anemia. Although Addison's descriptions of what we know now as pernicious anemia were of some accuracy, it is curious that he chose to bracket his descriptions of the anemic disease with those of the suprarenal capsule. Also in 1855, Virchow first accepted the term leukemia, after his original description of "Weisses Blut," and this name has stuck. Purpura and plethora, conditions of ancient lineage, were classified and subclassified; but without laboratory studies, little progress could be made. For all of these conditions, even for many cases of anemia, "bleedings" were performed as an important means of therapy. In chlorosis, the "green sickness," however, Sydenham the English clinician (1624-1689) and later Pierre Blaud in 1832 used large doses of iron with excellent results.

In 1856 the place of the laboratory in hematological studies was primitive indeed. Blood cells were examined in the fresh state without staining; blood cell counting was just beginning (Vierordt, Welcker). But, in the next two decades, great strides were made. First, there was the development of hematometry (Potain, Malassez, Gowers, Hayem). Later came the introduction of analine dye staining techniques by that great genius, the father of hematology whose 100th birthday we celebrated two years ago, Paul Ehrlich. May I quote from an editorial of mine published in *Blood* two years ago:

> The impact of Ehrlich's discovery and its widespread effects on many fields cannot of course be assessed, but it was certainly considerable. It is illustrative of the importance of the development of a method—for this simple staining technic made possible the study of many different kinds of blood cell reactions, including those found in infections, in the different types of anemia, and in leukemia. In the blood, he devised differential counting, made sharp distinctions between the various types of leukocytes and their granules, described polychromatophilia and poikilocytosis, and pointed to the close relationships existing between the blood picture and the bone marrow.
>
> For the first time the marrow could be adequately stained and carefully studied. Here, Ehrlich described the myelocyte, which he considered as the precursor of the granulated white cells of the blood; the megaloblast of pernicious anemia, which he distinguished from the normoblast; the mast cell; and the fatty picture of aplastic anemia.

There can be no question of the enormous effect the introduction of these two rather simple methods, cell counting and cell staining, had on the development of hematology. It was now possible to recognize and describe all manner of "new" diseases, previously "hidden" from view. Hematology threw off its colorless shackles and dazzled its devotees with Ehrlich's reds, blues, and violets; sometimes too much so, to judge by the lengthy polemical articles that were written by such masters as Pappenheim, Nägeli, and their contemporaries.

By 1900, hematology was well on its way. In Ehrlich and Lazarus' textbook, published at the turn of the century, there were large chapters on normal and pathological physiology of the blood, simple chronic anemia, progressive pernicious anemia, chlorosis, acute lymphatic leukemia, chronic lymphatic leukemia, pseudoleukemia, and myeloid leukemia. Hayem went further. His textbook "Du Sang," published in 1889, and his "Leçons" of 1900, did more to put hematology

---

Presidential address, read before the sixth Congress of the International Society of Hematology, Boston, Aug. 29, 1956.

on a firm basis than almost anything else. It was easy to see how far ahead of his time was this little giant who trod the Parisian scene for so many years. His descriptions of purpura hemorrhagica, in which for the first time he noted that the platelets (hematoblasts) were greatly reduced; his discussions on paroxysmal hemoglobinuria, cyanosis, hyperglobulia, and other subjects are just as fresh now as they were when they were written 56 years ago. In 1900, too, Landsteiner, then a Viennese, while working in the old Allgemeines Krankenhaus, made his epic discovery of the blood groups and before that, with Donath, was the first to find an autohemolysin in paroxysmal hemoglobinuria.

Advances in Hematology in the Twentieth Century

It was an auspicious beginning for the new century. Hemolytic anemia was first distinguished and studied extensively by various groups in Paris and Italy. Here in America Herrick, in 1910, first described sickle cell anemia. Banti focused his attention on the spleen as a hemolytic and "noxa"-producing organ and was the first (with Micheli) to recommend splenectomy as a therapeutic procedure. In 1916 Kaznelson instituted splenectomy for idiopathic thrombocytopenic purpura. Experimental and physiopathological hematology were beginning. Transfusions, based on Landsteiner's principles of blood grouping, began to be used, particularly when citrate was introduced as an anticoagulant by the Argentinian Agote in 1915 and by Lewisohn in New York (1914-1916). Leukemia was treated first by chemicals (arsenic, benzol) but later by x-rays, radium, and mesothorium.

By 1923, hematology was a rather dull, but respectable specialty: in some areas dominated by the pathologists; in some, as in New York, by the transfusionists; and here in Boston by the clinicians. We had here at that time Richard C. Cabot, whose horizons had already extended beyond hematology; James Homer Wright of megakaryocyte-platelet fame; and George R. Minot. Minot was fundamentally a clinician but at the same time an investigator. He believed passionately in clinical investigation; i. e., noting the problem in the patient, taking it to the laboratory for experimentation, bringing back the findings of the laboratory for further enlightenment in the clinic. With James H. Means, he talked to us constantly at school of the pathological physiology of disease and alluded only briefly to the morphologic aspects of the blood cells, so beloved by the European hematologists. Whipple's experiments indicating the remarkable effects of liver in the hemorrhagic anemia of dogs led Minot to try this substance in pernicious anemia with the almost incredible results all of of you know so well. This may be said to have opened up and revitalized the whole field of hematology, so that now its rate of advance became well-nigh phenomenal.

Castle's studies of the "conditioned" deficiency state of pernicious anemia led the way in the new pathophysiology of hematology. The hemolytic diseases opened up; at first the immunological forms: autoimmune and iso-immune; later, the pathophysiology of the hereditary forms, spherocytosis and sickle cell disease, were investigated. A rare mysterious disease, paroxysmal nocturnal hemoglobinuria, opened up all kinds of new vistas in intravascular blood destruction, iron deposition and excretion, the effects of plasma constituents on the abnormal red blood cells of the disease, and many other fascinating subjects. Polycythemia with its numerous manifestations, multiple myeloma with the many abnormalities due to the abnormally high plasma globulins, even the leukemias—all became subjects for intensive studies in the pathological physiology of disease.

With the introduction of corticotropin (ACTH) into the clinic, even such a prime morphologic favorite as the eosinophil became involved in the endocrine sphere. The concept of an erythropoietic hormone was revived, and humoral regulation of the lymphoid and splenic tissue became subjects of lively discussion.

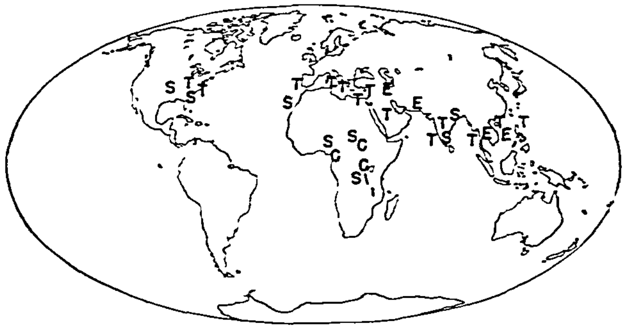

Fig. 1.—The "geohematology" of the hemoglobinopathies. T=thalassemia, S=sickle cell disease, C=hemoglobin C disease, E=hemoglobin E disease. The abnormal hemoglobins and the associated diseases are found in a broad central band of countries around the world and usually in people with some type of skin pigmentation, brown to black.

In the field of the leukemias and the white blood cell tumors (leukosarcomas), chemotherapy in the form of radiomimetic chemicals (notably nitrogen mustard) and of antimetabolites in the form of analogues of vitamins (notably the folic acid antagonists) held promise of the eventual control of these dread neoplastic conditions. Newer methods for studying the disordered blood cells, such as electron microscopy, phase microscopy, histochemistry, and time-lapse cinematography, opened up new vistas in the old field of morphology and linked the histology of the cell with its physiology. However, as newer insights into disordered function were developed, it became more and more evident that it was essential to study the actual chemical changes which took place in cells, tissues, plasma, excretions—in other words, the whole metabolism of a process, not alone its disordered physiology.

Iron, desoxyribose nucleic acid, ribonucleic acid, the various protein constituents of blood, and the coagulation factors, to mention but a few, were intensively studied. The radioactive isotopes opened up the possibility of tagging various constituents of cells and tissues. Simultaneously, the discovery by Pauling of an electrophoretic abnormality in the hemoglobin of sickle cell disease led to the discovery of all manner of "new" hemoglobins (such as C, D, E, G, H, I, and J) and to an enormous expansion in the knowledge of the "hereditary" hemoglobin disorders and of their racial and geohematological manifestations (fig. 1). It seemed that every road led to the fundamental chemical processes of the cell and its metabolic activities and to the inner mysteries of the disease itself. Morphology, physiology, therapy—all required the chemical approach.

One can distinguish thus three great eras of hematological development in the past century, actually even since 1900: (1) the era of morphology and of descriptive studies, 1856-1926; (2) the era of physiopathology, 1926 to the present; and (3) the era of chemistry, 1945 to the future. Illustrative is what has happened in hereditary spherocytosis (fig. 2). In era 1, there are the descriptions of the disease (acholuric jaundice, familial hemolytic jaundice) and of the abnormal cell involved, i. e., the spherocyte; and there are studies of the hypotonic fragility and the thickness-diameter ratio. In era 2, there are studies of the disturbed physiology: the bile pigment output, the life span of the red blood cell, the mechanism of splenic trapping, and the reasons for the remarkable effects of splenectomy. In era 3, our own, we begin to study the "why" of the spherocyte itself, its chemistry, its carbohydrate enzymatic abnormality, and even methods by which the abnormal cell might conceivably be modified. Similar thoughts hold true for sickle cell anemia (fig. 3).

Hematology in 1956 has thus become an exceedingly diverse and complex field, so much so that to few men given the ability to encompass all of it. The simple little hematology laboratory of 1920 or thereabouts has blossomed out into a state of complexity. Simultaneously, the expense of hematological investigation has risen almost perpendicularly. One sometimes wonders whether productivity has gone up at a parallel rate. To cover the expanding literature of hematology, many new journals have been founded, three in the past few months. One of them "Thrombosis et Diathesis Haemorrhagica" is the first devoted to a subspecialty of hematology.

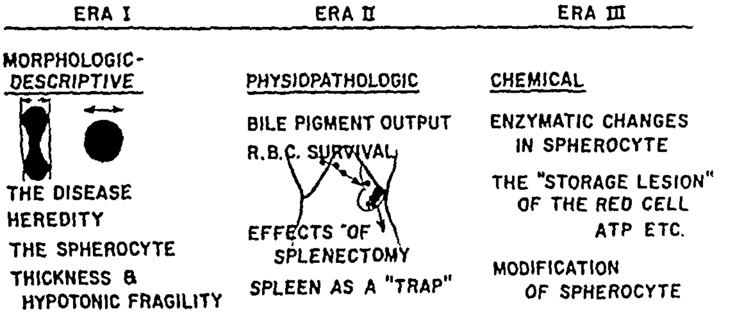

Fig. 2.—Eras of concepts concerning heredity spherocytosis in the last century.

Hematology in the Future

We have seen hematology in the past, and we have noted the present status of hematology. What is to be the future? There can of course be no doubt of the ever-increasing expansion of the field and of the division and subdivision of such fields as the coagulation disorders, immunohematology, and the hemoglobin abnormalities, to mention but a few. Soon one man will hardly be able to encompass even one fraction of one of the hematological subspecialties. This is by no means an unmixed blessing, as we note the extreme erudition of the younger group concerning a certain very small field of hematology and their relative ignorance when other fields are discussed.

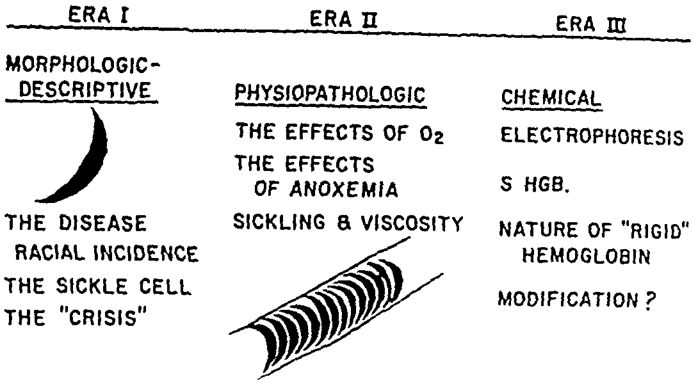

Fig. 3.—Eras of concepts concerning sickle cell disease in the last century.

What can one prophesy further? Certainly the gradual, perhaps the quick, control, as their mechanisms are worked out, of a number of now hopeless or near hopeless conditions. For example, one can with some justification predict that leukemia will be controlled; not necessarily cured, but controlled. The amazing specificity of some of the chemotherapeutic methods, the possibility of a viral etiology for at least some cases of leukemia, and therefore the possible development of methods of prophylaxis as in poliomyelitis—these are optimistic portents. Methods for bone marrow preservation and for bone marrow transfusion will almost certainly be developed. The necessity is there; the tools for preserving marrow are at hand; more work and techniques are all that are required. Bone marrow stimulants, conspicuous nowadays by their lack, will undoubtedly be found.

The chemical and enzymatic defects of the red blood cell in the hemoglobinopathies will almost certainly be discovered and perhaps then methods devised for so modifying them that the red blood cell survival will become normal. For the hemophilias, undoubtedly the deficient materials (such as antihemophilic globulin) will be concentrated and prepared for daily injection like insulin. One can speculate about the possible development of antiantibodies which could conceivably control certain cases of hemolytic anemia, leukopenia, and thrombocytopenia.

It is well to realize that, in all of these developments to come, we must be dependent not only on what we ourselves do in our own laboratories but upon the work of our colleagues in other cities, in other lands. No scientist works in a vacuum, and we rely more than we realize upon the work of many individuals, upon our contacts in meetings such as this, and upon the world's medical literature. In the nature of things, science can never be parochial.

This brings us to the last portion of this discourse. One would be remiss at an international gathering of this sort not to mention something of the political problems and their implications. Doctors, particularly hematologists, are of course a highly specialized group, but they work within the framework of society and must therefore enter into it as active participants. Gathered here is a cross section of men and women from various lands, men and women of various religions and political beliefs—a microcosm. In many cases these people have come here despite considerable difficulty, financial for the most part, political in some cases. They have come here as men of good will, intensely interested in gathering as much knowledge as possible and passing on what they themselves know to their colleagues—of whatever land and of whatever political belief. Such has been the custom of scientific groups for centuries. Our delegates have seen that their colleagues of another country, another continent, or another political belief are fundamentally the same sort of people, equally dedicated to their work as physicians, anxious to learn, anxious to teach—in other words, a great fraternity.

This is the most important lesson I myself learned on my recent world tour, part of it behind the so-called Iron Curtain. Face-to-face contacts inevitably lead to the simple but profound conclusion that people are fundamentally the same, with similar aspirations and ideals, whatever their language or their skin color. Such contacts must surely help to reduce the often artificially exaggerated differences between people of one country and another. An international gathering of this sort, and gatherings of other groups of scientists or business men or farmers or even of plain tourists, will surely break down barriers, whether iron or bamboo. This is a very important first step toward world peace and toward doing away with mankind's number one disease—war. As physicians and investigators, we need a steady "climate" of peace so that we can proceed unhindered in our studies and in the ultimate conquest of man's illnesses and man's fears. As hematologists, we must ever work to prevent useless blood loss and to conserve this most precious fluid for an increasingly healthy society.

New England Center Hospital, Harrison Avenue and Bennet Street.

HEPATIC-TYPE "FLAPPING TREMOR" OCCURRING IN PATIENTS WITHOUT HEPATIC DISEASE

Cheves McC. Smythe, M.D., Charleston, S. C.
and
Naseeb B. Baroody, M.D., Florence, S. C.

The alteration of consciousness and the aberrant behavior of patients with severe hepatic disease in its terminal stages have been known to clinicians for years.[1] However, not until Adams and Foley [2] reported the results of a clinical and pathological study of the neurological changes found in patients dying of cirrhosis and other hepatic diseases was the significance of the abnormalities seen in these patients widely appreciated.

As a result, clinicians now have a new sign commonly called the "liver flap" or "flapping tremor." Adams and Foley [2] describe this as follows:

Clinicians have a new sign commonly called the "liver flap" or "flapping tremor," described as a characteristic type of involuntary movement or "peculiar intermittency of sustained muscle contraction." While primarily a useful sign of impending liver failure it has also been observed in patients with uremia, polycythemia vera, severe malnutrition, and steatorrhea. In addition, the sign has been found in some patients with azotemia without hepatic disease. It is emphasized that this type of tremor although characteristic of, is not solely diagnostic of, impending or existing hepatic failure.

From the Medical College of South Carolina and Roper Hospital (Dr. Smythe) and McLeod's Infirmary (Dr. Baroody). Dr. Smythe is a Markle Scholar and Associate in Medicine at the Medical College of South Carolina.

> . . . a characteristic type of involuntary movement. This was most consistently and effectively demonstrated by having the patient hold his arms and hands outstretched with the fingers spread apart. Depending on the severity of the process, as this posture was maintained there appeared at irregular intervals of a fraction of a second to seven seconds, a series of movements consisting usually of lateral deviations of the fingers, flexion-extension of the fingers at the metacarpophalangeal joint, and flexion-extension at the wrist. The movements were rapid and arrhythmic, and one phase . . . was always more rapid than the other. They tended to occur in bursts, at a rate of every second or two.

This "peculiar intermittency of sustained muscle contraction" has emerged as a most useful sign of impending liver failure. However, Adams and Foley,[2] in their original paper, mention that they had observed it in two patients with uremia and in three with polycythemia vera. More recently Cooke[3] has described this sign in patients with severe malnutrition and in three patients with steatorrhea.

A young woman with lupus erythematosus disseminatus and moderate azotemia and a young man with hypertensive cardiovascular renal disease were observed to have gross "flapping tremor" for a period of a few days. Their cases are being reported to reemphasize Adams and Foley's original contention that this type of tremor, although characteristic of, is not diagnostic of, impending or existing hepatic failure.

Case 1.—A 34-year-old Negress was first noted to have a butterfly rash in July, 1953. Aside from chronic pelvic inflammatory disease, mild toxemia during her last pregnancy in 1948, and a doubtful serology, nothing was noted of apparent significance to her later illness during her long attendance at various clinics of the Roper Hospital. A tentative diagnosis of lupus erythematosus was made but not proved, and the patient was later considered to have seborrheic dermatitis. Four months later she developed pneumonia in the lower lobe of the left lung with pleural effusion which necessitated hospital admission. On this admission, albumin, red and white blood cells, and casts were found in the urine. A bone marrow preparation was positive for L. E. cells.

The patient did not improve satisfactorily after discharge, and readmission was necessary seven months later, in June, 1954, for pyoderma. In the interval the patient had developed asthma, and she was hypertensive, with a blood pressure of 180/100 mm. Hg. The urinary sediment was again grossly abnormal. After her discharge, repeated infections of the skin, conjunctivas, and external auditory canal plagued her. She was readmitted to the hospital in November and in December cortisone therapy was started. Her blood pressure was at a level of 170/110 mm. Hg. In the days before admission, she had noted that her rash had become more papular. After an episode of gross hematuria, her temperature was 103 F (39.4 C), and she was admitted with a diagnosis of bilateral pneumonitis. Physical examination revealed an obese moon-faced woman in considerable respiratory distress. There was hyperpigmented papular rash over the bridge of her nose and cheeks. Her temperature was 100.4 F (38 C), pulse rate 120 per minute, respirations 22 per minute, and blood pressure 140/100 mm. Hg. The heart was slightly enlarged and, except for sinus tachycardia, was otherwise not remarkable. Dulness to percussion was found over the left lower lung field, and fine rales and expiratory wheezes were heard at the bases of both lungs. The liver was palpable at the right costal margin and was tender. The area of hepatic dulness was not increased. There was generalized abdominal tenderness. Laboratory data for this case are summarized in the table.

On her fourth hospital day the patient developed acute respiratory distress with severe pleuritic pain on the left side and signs of acute left-ventricular failure. Her temperature was 104.2 F (40.1 C). She began to cough pink sputum in which pneumococci were seen (later cultured) on Gram staining. She was thought to have pneumococcic pneumonia of the lower lobe of the left lung and acute pulmonary edema. She responded to intravenously given lanatoside C and tetracycline. Pleural effusion later appeared on the left and the liquid was aspirated.

After this acute episode the patient improved. On the morning of Nov. 18, or four days after the acute episode and eight days after admission, it was noted that she had developed a spontaneous arrhythmic tremor of her hands. This was accentuated when the arms were extended and involved primarily the fingers and wrists. The flexor phase of the tremor was more rapid than the extensor. The patient was quite alert and was well aware of the jerking, which she could not control. The tremor was much worse in the morning and tended to decline as the day progressed. At the time the tremor was first noted, the patient was receiving prednisone, 25 mg. every six hours; tetracycline, 200 mg. every six hours intramuscularly; sulfisoxazole (Gantrisin), 1 Gm. every six hours by mouth; aminophylline suppositories; 0.5 Gm. every four hours; digitalis, 0.1 Gm. daily; phenobarbital sodium, 30 mg. every six hours; and codeine, 30 mg. every four hours, principally for pain. When the tremor was noted, the prednisone dosage was cut to 15 mg. every six hours and the use of the barbiturate was discontinued.

Laboratory Data for Case 1

Date, 1955	Nov. 12	Nov. 20	Nov. 21	Nov. 28	Dec. 2	Dec. 5
Leukocytes, thousands/cu. mm.	34.5	23.7			9.2	
Hemoglobin, Gm./100 cc.	12.5	11.5			10.5	
Urinary specific gravity	1.012		1.020		1.018	
Urinary albumin	4+		3+		3+	
Leukocytes, high-power field	20-30		50		300	
Erythrocytes, high-power field	1-2		10-15		10-15	
Blood urea nitrogen, mg./100 cc.	18	126	63	29		24
Blood sodium, mEq./liter	140	138	140	135		139
Blood potassium, mEq./liter	4.5	7.5	6.2	5.1		4.6
Carbon dioxide, vol. %	38		40			46
Calcium, mg./100 cc.			8.7			7.5
Phosphorus, mg./100 cc.			10.4			5.4
Total protein, Gm./100 cc.	6.79					
Globulin, Gm./100 cc.	3.66					
Alkaline phosphatase, King-Armstrong units/100 cc.		9.6				
Sulfobromophthalein retention, %			0			
Cephalin-cholesterol flocculation		Negative				
Prothrombin time, %			100			

The next day the tremor was still present, and the day after that it was at its height. On this day the patient had difficulty holding a glass, but she was able to walk, although unsteadily because of weakness. At no time were abnormalities of reflexes or muscle tone noted. An electroencephalogram was not made. Blood-chemistry findings at this time are noteworthy for a blood urea nitrogen level of 126 mg. per 100 cc. (63 mg. the next day), a calcium level of 8.7 mg. per 100 cc., and a phosphorus level of 10.4 mg. per 100 cc. All hepatic-function tests were within normal limits (see table). The liver was not enlarged, and there was minimal tenderness in the right upper quadrant. There was no icterus. Four days after the tremor appeared, it began to decline, never to reappear. The patient is progressing fairly well, without azotemia at present, on therapy with 20 mg. of prednisone a day.

Case 2.—A 33-year-old Negro man was admitted to McLeod's Infirmary, Florence, S. C., on Jan. 4, 1956, complaining of epigastric pain of one week's duration. He had vomited intermittently for two to three days prior to admission and during the same time had noticed the onset of a nonproductive cough. He gave a history of hypertension, which had previously been asymptomatic.

On physical examination he was found to be a well-developed, well-nourished male, complaining of abdominal pain. His temperature was 98.6 F (37 C), pulse rate 88 per minute, respirations 22 per minute, and blood pressure 260/140 mm. Hg. Examination of the eyes revealed pale fundi with severe arteriovenous nicking and an arteriovenous ratio of 1:4. The chest was symmetrical, and the lungs were clear to percussion and auscultation. The heart was enlarged to the sixth intercostal space at the anterior axillary line. The border of the left side of the heart was percussed 3 cm. lateral to the midclavicular line. The rhythm was normal, and the aortic second sound was louder than the pulmonic second sound. There was a soft blowing systolic murmur at the apex. Examination of the abdomen revealed epigastric tenderness. The liver was not enlarged and the spleen could not be felt. There was no costovertebral tenderness. The examination otherwise showed results within normal limits.

The laboratory data were as follows: erythrocyte count 3,350,000 per cubic millimeter, hemoglobin level 11.5 Gm. per 100 cc. (69%), leukocyte count 13,600 per cubic millimeter, polymorphonuclear leukocytes 71%, lymphocytes 13%, monocytes 4%, and eosinophils 2%; there was slight poikilocytosis. Urinalysis showed a specific gravity of 1.010, a pH of 7.0, albumin 2+, and sugar negative. There were 2 to 3 leukocytes per high-power field, innumerable erythrocytes, pinkish amber color, and no casts. The serologic test for syphilis was negative. The blood urea nitrogen level was 68 mg. per 100 cc., and the serum amylase level was 72 units. Sickle-cell preparation revealed no immediate sickling, 60% sickling in 24 hours, and 100% in 48 hours. An electrocardiogram was interpreted as indicating sinus tachycardia, left-axis deviation, left-ventricular hypertrophy, and coronary insufficiency. A roentgenogram of the chest revealed cardiac enlargement. Diagnoses of hypertensive cardiovascular renal disease with probable chronic glomerulonephritis, azotemia, sicklemia, and gastritis were made.

The patient was given atropine sulfate, 0.6 mg. every four hours; aluminum hydroxide (Amphogel), 8 cc. every eight hours; magnesium sulfate, 4 cc. intramuscularly every six hours for four doses; and phenobarbital, 30 mg. every eight hours. He was put on a low-salt diet and given 0.4 mg. of digitoxin every eight hours for three doses, then 0.1 mg. daily. His urinary output was good. Fluids were given ad libitum. He was then given 40 mg. of pentolinium tartrate every eight hours. By the fourth hospital day, the blood pressure had dropped to 190/90 mm. Hg and the patient complained of syncope on standing, although he seemed generally improved. Pentolinium dosage was reduced to 20 mg. every eight hours. By the seventh day, the blood pressure once again rose to 240/140 mm. Hg and intractable singultus was noted, for which 25 mg. of chlorpromazine was given every three hours, with little benefit. By the eighth hospital day the blood urea nitrogen level had risen to 117 mg. per 100 cc., singultus continued, and the patient was somewhat lethargic. The blood pressure remained elevated, and the pentolinium dosage was increased to 100 mg. every eight hours. On the ninth hospital day, the blood pressure was 236/140 mm. Hg. The specific gravity of the urine on three separate occasions was 1.010. On the 10th hospital day pentolinium dosage was increased to 200 mg. at 8 a. m., 100 mg. at 2 p. m., and 200 mg. at 8 p. m. The following day there was a drop in blood pressure to 180/110 mm. Hg. On this day, it was noted that the patient's lethargy was somewhat increased and that he had a definite "flapping tremor" when the arms were extended. The flexion-extension tremor involved the fingers, wrists and hands, and infrequently the entire arm. He could answer questions in a logical manner, but his speech was slurred and his responses were extremely slow and delayed. If undisturbed for a few minutes he would fall asleep. Neurological examination at this time revealed intact cranial nerve function and normal deep-tendon reflexes. No abnormal reflexes were observed. No electroencephalogram was taken. By the 12th hospital day the blood pressure reached 200/120 mm. Hg and the patient seemed more alert. The tremor was no longer demonstrable. Singultus was noted only at irregular intervals and the patient appeared to be completely clear mentally. The blood urea nitrogen level was 81.6 mg. per 100 cc. the next day, and the total serum bilirubin level was 0.43 mg. per 100 cc. Cephalin flocculation was 2+ in 24 hours and 4+ in 48 hours. This was considered to be consistent with the sicklemia. The patient was alert and cheerful and took food and fluids well. For the next five days, his consciousness varied from alertness to mild lethargy, at which time he would answer questions logically but in a sluggish manner. The tremor was not subsequently demonstrated. The blood urea nitrogen level on the 18th hospital day was 71.6 mg. per 100 cc. The patient remained alert, ambulatory, and asymptomatic, except for slight postural dizziness, until discharge on the 20th hospital day.

On Feb. 22, 1956, the patient was readmitted with recurrence of abdominal pain, nausea, and vomiting. He had discontinued taking digitalis and presented recurrent symptoms of of orthopnea, dyspnea, and edema. On physical examination the blood pressure was 190/130 mm. Hg and there were scattered moist basilar rales in both lungs. The heart was enlarged and the apex was in the sixth intercostal space at the anterior axillary line. The abdomen was soft and flat and there was moderate midepigastric tenderness. The liver was slightly tender and the lower edge was palpated at the right costal margin. There was 2+ pitting edema of both lower extremities, and diagnoses of malignant nephrosclerosis with hypertensive cardiovascular disease and congestive heart failure were made. The blood urea nitrogen level was 130 mg. per 100 cc. and the hemoglobin level had dropped to 5 Gm. per 100 cc. For the next five days his condition was poor. He developed urinary retention and on several occasions catheterization was necessary. Nausea and vomiting continued. On the fifth hospital day he became irrational and confused. He died on the seventh hospital day.

At autopsy, the final anatomic diagnoses were (1) marked generalized arteriosclerosis, (2) marked cardiac hypertrophy (cor bovinum), (3) arteriolar nephrosclerosis, (4) focal myocarditis, (5) acute and chronic pancreatitis, (6) congestion of viscera, and (7) lipoma of the left adrenal gland.

Comment

These are complex cases. It is, however, fair to say that neither patient had clinically apparent hepatic disease and that there was little evidence of hepatic dysfunction. The first patient had lupus erythematosus with findings indicative of renal injury and evidence of lowered resistance to infection. The second had renal failure on the basis of nephrosclerosis. At the time of the episode of "flapping tremor" both patients were markedly azotemic, and it was thought that death from uremia would rapidly ensue in each instance. However, those who observed the tremors in these cases felt that these were not the extensor twitches or spasms or jactitations of uremia but true flexion-extension tremors identical with those seen in patients with hepatic failure. They were not caused by simple loss of muscle strength. It is of interest to note that, in the first patient, after the dosage of prednisone (which had been increased with the idea that it might control the apparently increasing renal damage) was reduced and then omitted, the kidney status improved rapidly. The same sequence with pentolinium tartrate occurred in the second patient. It should also be mentioned that the first patient was having considerable respiratory distress at the time of the occurrence of the tremor. Although arterial oxygen saturation was not measured, the patient was not clinically cyanotic. Bessman and Evans[4] have noted elevated blood ammonia concentrations in chronic congestive failure.

In the past few years the major investigative effort on the pathogenesis of hepatic coma has been directed at determining the exact role of ammonia and at elucidating the disorder of its metabolism seen in such patients. Although probably not the only factor, retention of ammonia is recognized as being closely related to the clinical picture of hepatic coma.[5] However, the severity of the neurological disturbance has not been found to correlate too closely with peripheral venous levels of blood ammonia.[6] Webster[7] has postulated that the cerebral production, and therefore the ammonia content, of jugular venous blood may be a determining factor. The severity of the neurological disturbance has also been found to correlate most closely with the arterial blood ammonia level.[8] Most of these investigations have been concerned largely with the alteration of consciousness. Whether the tremor is related to the same metabolic derangements as the stupor is not definitely known, but probably it is related. The close resemblance of the tremor to other neuromuscular disorders arising from disease of the basal ganglions and the description of astrocytic abnormalities in this portion of the brain[2] are evidence of a special sensitivity of the cells of this area to the abnormal metabolic processes involved.

Adams,[2] Davidson,[9] and Bessman[6] have observed that persons with uremia demonstrate a typical "flap." Bessman[8] has reported on blood ammonia levels in four persons (part of his comatose control group) with uremia. All levels were within the normal range. It has been pointed out that this is to be expected, since, in part, ammonia levels depend on renal production, and in uremia this source is markedly curtailed.[5] Moreover, since many feel that high blood ammonia levels in persons with cirrhosis are almost totally dependent upon escape of the ammonia in the general circulation via collateral channels bypassing hepatic parenchyma,[10] one would not expect a high ammonia blood level in persons with uremia, without liver disease, and in whom no such collateral circulation exists. No description of ammonia retention in patients with uremia has been found. Therefore, the patients in our study, having intact liver function and absence of an extensive collateral circulation, may be assumed to have had normal ammonia levels, although it cannot be concluded definitely that there was no ammonia retention without actual measurements. This leads to the conclusion that the tremor of hepatic coma may not be due solely to ammonia retention and that the neurological disorder seen in these patients probably had other contributing causes.

Summary

A "flapping tremor" occurred in two patients who had azotemia but not hepatic disease. Both patients recovered from the episodes of renal failure. One patient subsequently died, and at autopsy the liver was found to be essentially normal.

Addendum

The first patient has subsequently died. At autopsy there was no liver disease. The kidneys showed extensive changes consistent with a diagnosis of lupus erythematosus.

Sudden Deafness.—A study was made of 178 cases of sudden deafness of obscure cause encountered in a five-year period, 1949 to 1953, inclusive. In 89 cases the deafness seemed to be due to a vascular accident. In 56 it seemed to be due to Ménière's disease. In 17 the cause could not be determined. In 15 it was due to miscellaneous causes usually of infectious origin. In one case the deafness was thought to be due to hysteria or malingering. The literature, pathology, etiology, diagnostic factors and other pertinent data were considered in some detail. Because of the absence of specific information as to the underlying pathology, the diagnosis as to etiology has to be somewhat tentative; however, in most of the cases studied, repeated and extensive examinations permitted a statement as to etiology which is considered fairly authoritative.—O. E. Hallberg, M. D., Sudden Deafness of Obscure Origin, *The Laryngoscope*, October, 1956.

SERUM LACTIC DEHYDROGENASE—A DIAGNOSTIC AID IN MYOCARDIAL INFARCTION

Roderick P. MacDonald, Ph.D., John R. Simpson, M.D.
and
Egon Nossal, B.S., Detroit

The usefulness of specific enzyme reactions to clinical medicine is becoming increasingly more apparent. Patients suffering destruction of various tissue cells have increased enzymatic activity in their serum. The enzymes normally present within the cells are liberated into the blood stream as cell destruction occurs. The determination of serum lactic dehydrogenase (LDH) as an aid in the diagnosis of acute myocardial infarction has two advantages: first the increased elevation is present for as long as six to eight days after attack; second, the technical procedure is far less complicated than other enzyme tests. LDH determination, not ordinarily necessary in the diagnosis of acute myocardial infarction, is particularly helpful when the electrocardiograph pattern masks the recent changes of an acute infarction.

Abnormally elevated serum enzyme levels resulting from tissue destruction are assuming increasing importance as diagnostic procedures. The discovery that glutamic oxaloacetic transaminase is released from cardiac tissue during myocardial infarction [1] led to a search for other enzymes which might behave similarly. Wróblewski and LaDue [2] noted the presence of lactic dehydrogenase (LDH) in serum and subsequently demonstrated its elevation after acute transmural myocardial infarction. Hill and Levi [3] previously reported finding an elevated level of a serum component in neoplastic disease which they believed to be lactic dehydrogenase. Others [4] have reported LDH elevations in various other disorders.

The present report describes the method of analysis for LDH and presents the findings in 174 hospital patients representing many different pathological conditions.

Method

Methods for the assay of LDH are usually based upon the oxidation or reduction of diphosphopyridine nucleotide (DPN) or reduced diphosphopyridine nucleotide (DPNH). These reactions are coupled with the conversion of lactic acid to pyruvic acid or vice versa. Maximum reduction by LDH occurs when pyruvic acid forms lactic acid. DPNH in this case furnishes the proton required for the reaction and is consequently oxidized to DPN. This is the principle of the procedure used in this study.

The method is essentially that of Wróblewski and LaDue.[2a] It has been modified by dilution of the serum when an appreciable drop in the rate of DPNH oxidation occurs during the period of measurement.

To 2.4 ml. of phosphate buffer (pH 7.4) add 0.1 ml. of serum and 0.1 ml. of DPNH (2.5 mg. per milliliter in water, made basic to pH 9.0 with sodium hydroxide). Allow to stand 20 minutes, then add 0.1 ml. of sodium pyruvate (2.5 mg. per milliliter). The optical density of the solution is then read every 15 seconds for 5 minutes at 340 mμ in a Beckman DU spectrophotometer. If the optical density decreases at an accelerating rate for each time interval, dilute an aliquot of the original serum with phosphate buffer and repeat the procedure using the original amounts of all constituents. Appropriate dilutions are indicated by the first minute readings: 1:3 if over 1,000, 1:4 if over 1,500, or 1:5 if over 2,000 units. Further dilution may be necessary if the LDH activity is extremely high. The rate of decrease of optical density is taken as a measure of LDH activity expressed as units per milliliter of serum per minute. One unit equals a decrease in optical density of 0.001 per minute per milliliter under the above conditions. Any dilution must also be considered in the calculation of the final value.

The 20-minute time interval after addition of the DPNH is required to permit the reduction of alpha-keto and alpha, gamma-diketo acids initially present in the serum. This reaction stops when the keto and diketo acids are enzymatically reduced to lactate by the added DPNH.

No specific dilution factor can be given since this will depend upon the LDH activity of the serum and the assay of the DPNH preparation used, for the latter may vary from one lot to another. Insufficient quantities of DPNH will be indicated by a decreasing rate of reaction. Serum dilution decreases the LDH activity to a known degree, thus making the amount of DPNH adequate for the reaction. If the rate of reaction is not periodically followed, an inadequate DPNH activity will not be apparent. Methods which measure optical density initially and after a specified time interval will give lower values than those obtained by the technique described above, especially if LDH activity is very high.

From the departments of pathology and internal medicine, Harper Hospital.

the patient was not clinically cyanotic. Bessman and Evans[4] have noted elevated blood ammonia concentrations in chronic congestive failure.

In the past few years the major investigative effort on the pathogenesis of hepatic coma has been directed at determining the exact role of ammonia and at elucidating the disorder of its metabolism seen in such patients. Although probably not the only factor, retention of ammonia is recognized as being closely related to the clinical picture of hepatic coma.[5] However, the severity of the neurological disturbance has not been found to correlate too closely with peripheral venous levels of blood ammonia.[6] Webster[7] has postulated that the cerebral production, and therefore the ammonia content, of jugular venous blood may be a determining factor. The severity of the neurological disturbance has also been found to correlate most closely with the arterial blood ammonia level.[8] Most of these investigations have been concerned largely with the alteration of consciousness. Whether the tremor is related to the same metabolic derangements as the stupor is not definitely known, but probably it is related. The close resemblance of the tremor to other neuromuscular disorders arising from disease of the basal ganglions and the description of astrocytic abnormalities in this portion of the brain[2] are evidence of a special sensitivity of the cells of this area to the abnormal metabolic processes involved.

Adams,[2] Davidson,[9] and Bessman[6] have observed that persons with uremia demonstrate a typical "flap." Bessman[8] has reported on blood ammonia levels in four persons (part of his comatose control group) with uremia. All levels were within the normal range. It has been pointed out that this is to be expected, since, in part, ammonia levels depend on renal production, and in uremia this source is markedly curtailed.[5] Moreover, since many feel that high blood ammonia levels in persons with cirrhosis are almost totally dependent upon escape of the ammonia in the general circulation via collateral channels bypassing hepatic parenchyma,[10] one would not expect a high ammonia blood level in persons with uremia, without liver disease, and in whom no such collateral circulation exists. No description of ammonia retention in patients with uremia has been found. Therefore, the patients in our study, having intact liver function and absence of an extensive collateral circulation, may be assumed to have had normal ammonia levels, although it cannot be concluded definitely that there was no ammonia retention without actual measurements. This leads to the conclusion that the tremor of hepatic coma may not be due solely to ammonia retention and that the neurological disorder seen in these patients probably had other contributing causes.

Summary

A "flapping tremor" occurred in two patients who had azotemia but not hepatic disease. Both patients recovered from the episodes of renal failure. One patient subsequently died, and at autopsy the liver was found to be essentially normal.

Addendum

The first patient has subsequently died. At autopsy there was no liver disease. The kidneys showed extensive changes consistent with a diagnosis of lupus erythematosus.

Sudden Deafness.—A study was made of 178 cases of sudden deafness of obscure cause encountered in a five-year period, 1949 to 1953, inclusive. In 89 cases the deafness seemed to be due to a vascular accident. In 56 it seemed to be due to Ménière's disease. In 17 the cause could not be determined. In 15 it was due to miscellaneous causes usually of infectious origin. In one case the deafness was thought to be due to hysteria or malingering. The literature, pathology, etiology, diagnostic factors and other pertinent data were considered in some detail. Because of the absence of specific information as to the underlying pathology, the diagnosis as to etiology has to be somewhat tentative; however, in most of the cases studied, repeated and extensive examinations permitted a statement as to etiology which is considered fairly authoritative.—O. E. Hallberg, M. D., Sudden Deafness of Obscure Origin, *The Laryngoscope*, October, 1956.

The time of onset of the attack leading to myocardial infarction was established in 38 patients. This was based primarily on the appearance of characteristic retrosternal pain, collapse, shock, or various arrhythmias. Such timing was not possible in six patients.

Serial determinations of LDH activity were obtained daily in many patients. Rise in LDH level in response to myocardial infarction began on the first day. Maximum levels were usually reached on the 2nd or 3rd day and slowly declined to normal by the 6th to 11th day. This trend is illustrated in figure 1, which utilizes LDH determinations in patients with definitely established onset.

A delay in return of LDH level to normal, or a secondary rise, implied extension of the infarction and often a much poorer prognosis. The LDH level of patient F. C. shown in figure 2 is illustrative. This woman died after 10 consecutive days of LDH elevation above 900 units. Extreme elevations (above 2,000 units) did not prove prognostically significant. Three patients with levels of 4,000, 2,950, and 2,960 units died, but two others with levels of 2,250 and 2,650 units had uncomplicated clinical courses. No correlation was attempted between the size of infarct at autopsy and the degree of LDH elevation. Fifteen patients died during the period of study for a mortality rate of 34%. Four hearts were studied at autopsy and all showed definite evidence of acute transmural myocardial infarction.

Infarction Suspects.—In 29 patients (19 males, 10 females, aged 39 to 74) recent myocardial infarction was suspected but not definitely established by initial studies. Thirteen of these had suffered previous myocardial infarction from two weeks to five years earlier. After careful and intensive study these 29 patients were finally given diagnoses as follows: angina pectoris, 8; coronary insufficiency, 15; and myocardial infarction, 6. There were no deaths during the period of study. All of the eight patients with angina had normal LDH levels.

Of the 15 patients with coronary insufficiency 10 had had a previous myocardial infarction and their electrocardiograms showed patterns of old myocardial infarctions that could have masked recent changes. In 7 of these 10 the LDH levels were normal while in the remaining 3 they were maximally elevated to levels of 545, 555, and 595 units. Actual myocardial necrosis probably occurred in these three patients.

In the remaining five without previous infarction, the electrocardiograms showed patterns of ischemia in all. Three of these had normal LDH levels but in the other two the levels were elevated to slightly over 400 units, probably due to small areas of subendocardial necrosis.

In the last group of six patients conclusive electrocardiographic evidence of infarction was lacking. Masking patterns of bundle-branch block and old infarction were present in five while in the sixth minor changes in lead AVL suggested lateral infarction. LDH levels in this group were slightly to moderately elevated (410 to 700 units). The lesser elevations (410 and 460 units) were found in the two patients with bundle-branch block. LDH levels in the three patients with old infarction were 615, 700, and 540 units. The man with the lateral infarction had his maximum LDH elevation (500 units) 36 hours after onset of pain. In this group, as in the previous ones, LDH elevations seemed to correlate with the presence of necrotic myocardial tissue.

Congestive Failure.—Of 12 patients admitted primarily for treatment of congestive heart failure, 4 had elevated LDH levels and 3 of these were above 600 units. The LDH level was 605 units in a woman with left bundle-branch block due to arteriosclerotic heart disease. A man with rheumatic heart disease and atrial fibrillation had an LDH level of 390 units. His ECG also showed nonspecific myocardial damage. Another man with rheumatic heart disease and atrial fibrillation had an LDH level of 775 units and an ECG which showed subendocardial ischemia. He died while in the hospital, but there was no autopsy. The fourth elevation occurred in a man with secondary polycythemia due to decompensated arteriosclerotic heart disease. His LDH level was 630 units on the day after admission and 340 units two days later. Two electrocardiograms showed severe diffuse myocardial damage and changes suggestive of lateral infarction. LDH elevation in these four patients may have been due to actual myocardial necrosis but final pathological proof was not available.

Pericarditis.—The diagnosis of pericarditis was established by clinical observation and electrocardiographic changes in four patients. In two the disease was felt to be of tuberculous origin, while in the other two no definite etiology could be proved. LDH levels were elevated (530 and 505 units) in the two patients with tuberculous pericarditis. Pericardicentesis was performed on both these patients and LDH levels were determined on the pericardial fluid. The LDH levels (530 and 570 units) approximated those of serum.

One patient with idiopathic pericarditis had consistently normal LDH levels while the other patient showed a transient elevation. LDH levels in the latter varied from 440 units when first studied to a maximum level of 640 units five days later, at the height of clinical disease. Fifteen days later the level had returned to normal.

The LDH activity of normal pericardial fluid has never been recorded, but it seems valid to assume that it would approximate that of serum. The most likely explanation for the increased LDH activity would be destruction of cells in the epicardial layer of the myocardium. Such destruction probably took place in the three patients with elevated LDH levels.

Liver Disease.—Twelve patients with primary liver disease were studied. Of six patients with viral hepatitis the LDH level was elevated in four studied during the acute stage. The highest level was 1,370

Hemolysis must be carefully avoided since the LDH activity of whole blood hemolysates is approximately 100 times that of serum.[28] Any perceptible hemolysis will give falsely elevated results. The serum may be stored at 4 C (40 F) for 3 days or frozen for 10 days.[3] Slightly lipemic or icteric serum may be used for the determination.[3]

The serum LDH activity in 40 normal adults selected from hospital personnel (20 males and 20 females, aged 20 to 64) varied from 165 to 332 units, with a mean of 247 units. Standard deviation for this series was 33 units. The mean ±2 standard deviation units (sigma) should include 95% of the values in the series (95% confidence limits of a normal distribution). Only one subject was found to have a serum LDH level above this (332 units). Therefore the normal range of LDH activity is below 313 units when determined by the above procedure.

Summary of Conditions Studied and Elevated LDH Levels

Disease	No. of Patients		LDH Elevations: Above Normal	LDH Elevations: Above 500 Units
Heart disease	94			
Angina pectoris		13	0	0
Myocardial infarction		50	50	44
Coronary insufficiency		15	5	3
Congestive failure		12	4	3
Pericarditis				
Tuberculous		2	2	2
Idiopathic		2	1	1
Liver disease	12			
Viral hepatitis		6	5	4
Laennec's cirrhosis		5	1	1
Traumatic necrosis		1	1	1
Pulmonary disease	8			
Pneumonia, lobar		4	2	0
Infarction		2	1	0
Lung abscess		1	0	0
Necrosis		1	0	0
Cerebral vascular accidents	11		11	3
Diabetes mellitus	7		3	0
Malignant disease	13			
Lymphomas		5	4	1
Multiple myeloma		2	1	1
Metastatic carcinoma		4	4	2
Sarcoma		1	0	0
Myelogenous leukemia		1	0	0
Hematological disease	5			
Sickle cell anemia		3	3	3
Hemolytic crisis		1	1	1
Infectious mononucleosis		1	1	1
Miscellaneous diseases	19		7	0
Pregnancy	5		1	0
Totals	174		108	71

Clinical Studies

Clinical material consisted of 174 hospitalized patients, 94 with organic heart disease. Seventy-eight patients were suffering from coronary artery disease. In addition to frequent clinical observation, cardiac patients were studied by serial determinations of white blood cell count (WBC), erythrocyte sedimentation rate (ESR) by the Westergren method, 12-lead electrocardiogram (ECG), and LDH levels. Many other conditions were also studied, especially those considered in the differential diagnosis of acute myocardial infarction.

A tabulation of the conditions studied and the number with LDH levels above normal and above 500 units is shown in the table. Patients are grouped according to clinical diagnosis at the time of leaving the hospital.

Angina.—Of the 13 patients with angina pectoris, 5 were not suspected of having myocardial infarction. All five had essentially normal WBC, ESR, and ECG tests that in no way suggested or masked myocardial infarction. The LDH levels were normal in all. These results compare favorably with those of others who have demonstrated normal serum enzyme levels in the absence of myocardial tissue destruction.

Myocardial Infarction.—In 44 patients (37 males and 7 females aged 43 to 83) the diagnosis of acute myocardial infarction was definitely established by clinical, electrocardiographic, and/or postmortem pathological studies. The infarction was considered transmural in all. Six additional patients in whom the diagnosis of infarction was in doubt were considered separately as infarction suspects.

LDH levels were elevated in all 44 patients and above 500 units in 39 patients. The lesser degrees of elevation occurred under the following circumstances: Two patients whose single LDH levels of 320 and 380 units were determined 12 and 18 hours after onset of the attack died shortly thereafter. One patient, studied only on the first day, had an LDH level of 340 units. Definite onset time could not be established in another patient whose top level was 400 units. An elderly woman who suffered cerebral thrombosis at the time of coronary thrombosis had a maximum value of 495 units on the sixth day.

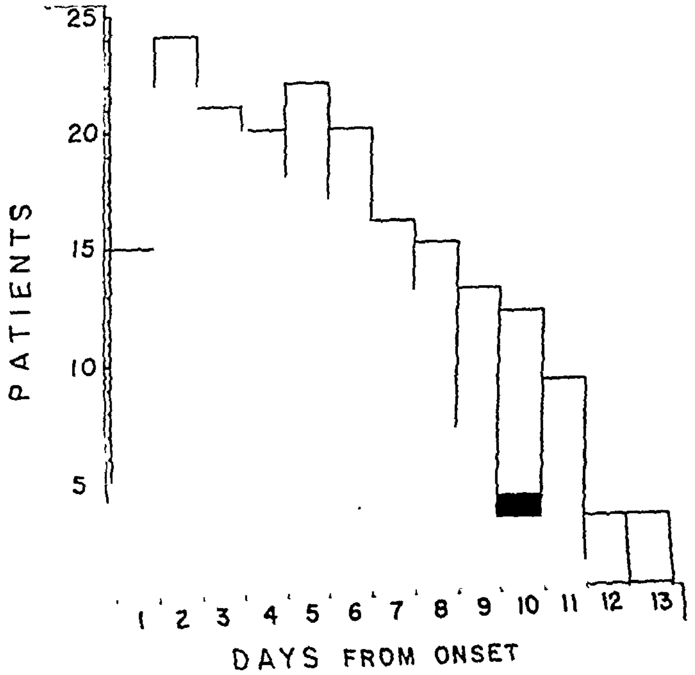

Fig. 1.—Significant elevations of LDH levels after acute transmural myocardial infarction. Total height of bar equals number of determinations. Shaded area denotes number of determinations above 500 LDH units.

destruction of various tissue cells. The enzymes normally present within the cells are liberated into the blood stream as cell destruction occurs. The degree of elevation of the particular enzyme under study depends on three factors: (1) the concentration of the enzyme within the cell; (2) the amount of tissue or the number of cells actually destroyed; and (3) the accessibility of the products of destruction to the systemic circulation where the measurement is actually made. These increased levels persist for varying periods after the destruction takes place, depending upon which tissue and which enzyme is involved. Although the enzyme determinations currently being employed reflect nonspecifically the response to destruction of several different tissue cells containing the same enzymes, such determinations yield useful information in many clinical situations. Probably the widest application of this principle to date has been the utilization of glutamic oxaloacetic transaminase as an adjunct in the diagnosis of acute myocardial infarction.[6] Other enzymes (hexose isomerase, lactic dehydrogenase, malic dehydrogenase, and aldolase) have also been used for this purpose.[4b] Glutamic oxaloacetic transaminase,[5e] glutamic pyruvic transaminase,[5f] and aldolase[7] have all been employed by various investigators in studying liver disease. The increasing usefulness of the application of these specific enzyme reactions to clinical medicine is becoming increasingly more apparent.

The results reported here demonstrate the value of LDH determinations as an aid in the diagnosis of acute myocardial infarction. To justify the use of this test there should be certain advantages over those methods currently more widely employed for the same purpose. We feel that such advantages do exist and that the most important one is the prolonged elevation that occurs after mycardial infarction. In a significant number this elevation will be present for as long as six to eight days after attack. This is distinctly helpful in those patients with less severe attacks of myocardial infarction who present themselves several days after the initial attack of pain. Another advantage is the less complicated technical procedure. The method is technically easier, requires fewer reagents, and less frequent determinations are necessary than with the transaminase test. The modified procedure herein described gives accurate values at any level of LDH activity.

Determinations of LDH, although confirmatory, are not ordinarily necessary in the diagnosis of acute myocardial infarction. However, there are situations in which they are distinctly helpful, particularly when the electrocardiographic pattern masks the recent changes of an acute infarction. This occurs not infrequently when bundle-branch block has developed and when patients have had previous myocardial infarction.

In following the course of a patient with recent infarction, a secondary rise in LDH level may indicate extension of the infarct when there are no additional changes electrocardiographically. Another situation in which LDH determinations may prove helpful is in patients with electrocardiograms that present prominent ST interval and T-wave changes without significant Q waves. Although such changes may simply reflect myocardial ischemia, they may also indicate actual necrosis, in either the subepicardial or the subendocardial layers of the myocardium. Under these circumstances an elevated LDH level would indicate actual tissue destruction rather than the less serious ischemia. The extent of LDH elevation in these situations however is usually less than that found with acute transmural myocardial infarction. The significant elevation in our series of patients with transmural infarction was a level above 500 units, which occurred in 39 of 44 patients (88.6%).

The determination of LDH levels may also be useful in the differential diagnosis of acute pain in the chest or upper part of the abdomen. Many acute conditions to be differentiated from acute myocardial infarction have normal LDH levels, e. g., acute cholecystitis, perforated peptic ulcer, pneumonia, pulmonary embolism, and pulmonary infarction. It is admitted that several other diseases (see table) may cause elevation of LDH levels, but these are generally not confused with acute myocardial infarction. The one exception is when coronary thrombosis with resultant myocardial infarction produces a shock-like state that leads to cerebral thrombosis. Both conditions produce significant degrees of LDH elevation, but in the latter condition it is usually less marked. Such a sequence of events occurred in one of our patients.

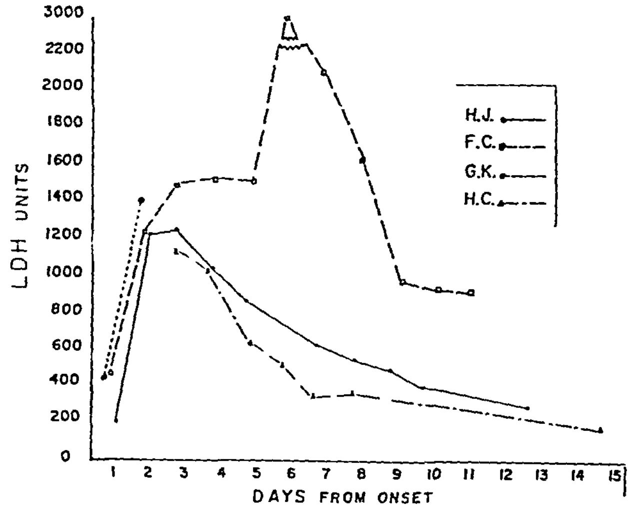

Fig. 2.–Characteristic responses of serum LDH levels after acute transmural myocardial infarction.

The various patterns of response reflected by serial LDH determinations are shown in figure 2. The usual response of rise and fall in an uncomplicated case is demonstrated by patient H. J. The prompt rise followed by death on the second day is shown in patient G. K. A stormy course terminating in death on the

11th hospital day is reflected in the determinations on patient F. C. Patient H. C., whose first LDH level was determined on the third day, showed the gradual decline that accompanies a very uneventful clinical recovery.

Other investigators[8] have reported elevated LDH levels in many clinical disorders in addition to myocardial infarction, such as hepatocellular necrosis, metastatic carcinoma, diabetic acidosis, leukemia, megaloblastic and sickle cell anemia, thrombocytopenia, malignant lymphoma, infectious mononucleosis, cerebral infarction and/or hemorrhage, and rheumatoid arthritis. In our studies elevations were also found in most of these conditions, with the exception of rheumatoid arthritis. We found in addition that the LDH level is elevated in acute hemolytic crisis.

These same authors[9] found many conditions associated with normal LDH levels. Included were acute and chronic infectious diseases, pulmonary infarction, localized neoplastic disease, diabetes, peptic ulcer, pancreatitis, cholecystitis, chronic nephritis and uremia, cirrhosis, fractures, myxedema, hyperthyroidism, and arterial thrombosis with gangrene of the leg. This was also true after minor surgery. Patients with heart disease without myocardial infarction usually had normal LDH levels. Our finding of essentially normal LDH levels in pregnant women is in disagreement with others.[3]

Wróblewski[2b] presented two patients in congestive failure with elevated LDH levels but without additional evidence of myocardial infarction. In our group of patients with congestive failure there were four with elevated LDH levels. It was our impression that actual infarction may have been present, but we had no pathological material to support this belief. Further investigation is required to settle this issue.

Although less attention has been focused on the value of LDH levels in other conditions, limited application has been attempted in the field of malignancy.[10] The only conclusion our material permits is the generalization that the degree of LDH elevation in malignant disease appears related to the extent of metastases.

At present it appears that LDH determinations are most useful in the diagnosis of coronary artery disease. In suspected myocardial infarction the serum LDH levels may make possible the diagnosis when all other methods have failed.

Summary

A modified method has been described for the determination of serum lactic dehydrogenase (LDH) activity. Elevations of serum LDH were found in myocardial infarction, hepatocellular necrosis, metastatic carcinoma, diabetic ketosis, sickle cell anemia, malignant lymphoma, infectious mononucleosis, and cerebral infarction. The response of LDH levels to myocardial infarction has been described.

This determination is especially useful when the electrocardiographic pattern is masked or when complications occur after myocardial infarction. It often helps to distinguish between ischemia and actual infarction and to differentiate conditions sometimes confused with myocardial infarction. The determination of LDH levels should therefore become a useful laboratory adjunct in the diagnosis of coronary artery disease.

CLINICAL NOTES

POSTOPERATIVE ACUTE ADRENAL CORTICAL INSUFFICIENCY

Ralph Adams, M.D.
and
Norman Siderius, M.D., Wolfeboro, N. H.

Until recently, it was common practice in the management of severe postoperative shock for surgeons to use adrenal cortical extracts in the hope that a lack of these substances might be an etiological or contributing factor in the production of shock.[1] A combination of two factors has been responsible for the common failure of such an approach: first, the relative rarity of adrenal cortical insufficiency in the etiology of shock, and, second, administration of inadequate doses of hormones. Knowledge of the physiology of adrenal insufficiency gained during the last five years has made it possible to base corticosteroid therapy on a firmer foundation.[2] Also, the concept of stress stemming from the extensive work of Selye [3] has helped to reveal the importance of the adrenal cortex in the body's response to a host of stressful situations, including major or minor surgery. Much has been learned from the study of patients with adrenal cortical hypofunction (Addison's disease) and patients who have undergone bilateral adrenalectomy.[2b] Modern replacement therapy allows one to operate on such patients with relative safety.[4] Now that it is possible to treat the patient with adrenal cortical insufficiency successfully, it becomes urgent to recognize the clinical condition when it exists.

We have encountered five cases of postoperative shock in which the diagnosis of adrenal insufficiency seems justified. There was no clinical reason to suspect a deficiency of adrenal function preoperatively in any one of these five cases. One of these is presented in detail to illustrate the problem of recognition and treatment.

Report of a Case

A 65-year-old woman was admitted to Huggins Hospital on Oct. 2, 1955, with a history of pain (heavy discomfort) in the right upper abdominal quadrant, penetrating to the right costovertebral angle posteriorly, and accompanied by nausea and vomiting (no hematemesis) of five days' duration. No other symptoms were elicited referable to cardiac or gallbladder disease. Urinary symptoms were denied. The patient's appetite was good, and there was no recent weight loss. The history revealed that the patient had been treated for laryngeal tuberculosis 35 years prior to admission and had thereafter apparently recovered. She had weakness of the back muscles of many years' duration, probably related to an early childhood injury.

Physical examination revealed a woman of small stature. The temperature and pulse and respiratory rates were normal. A movable, nontender, 8-by-12-cm. mass was felt in the right upper abdominal quadrant, and it extended into the right lower quadrant. Other physical findings were limited to the back muscles, which showed organic weakness, but posture was fairly good.

Laboratory determinations showed that the values for hemoglobin, hematocrit, white blood cells, nonprotein nitrogen, blood sugar and amylase, urinary diastase, icteric index, and the Van den Bergh reaction were all within normal limits. Urinary specific gravity was low. Chest x-ray films revealed multiple, tiny, old foci of calcifications at the apex of the left lung, with no evidence of tuberculous activity. Indirect laryngoscopy showed paresis of the left vocal cord and deformity of the larynx consistent with old tuberculosis.

Cholecystography revealed normal filling of the gallbladder and demonstrated a congenital constriction at the junction of the distal and middle thirds of the fundus. An intravenous pyelogram outlined a large tumor mass, at the lower pole of the right kidney, that contained no dye. The left kidney shadow was normal. Cystoscopy with the patient under spinal anesthesia was normal. Retrograde pyelography demonstrated a right ureteral obstruction interpreted as secondary to old tuberculosis. The postcystoscopy course was uneventful.

As part of the patient's preparation for surgery, aminosalicylic acid (PAS) and streptomycin were given to prevent tuberculous reactivation. At operation on Oct. 7, 1955, a large cystic tumor mass replacing the right kidney was mobilized and removed with minimal blood loss. Spinal anesthesia was used. Exploration of the abdomen revealed no disease and confirmed the presence of the congenital constriction of the gallbladder which had been seen on x-ray films. Pathological examination was reported as showing pyelonephrosis, hydronephrosis, and chronic ureteritis.

From the onset of operation there was a tendency toward hypotension and tachycardia; otherwise the patient's condition was good. Blood pressure was maintained by blood-loss replacement and the administration of phenylephrine (Neo-Synephrine) hydrochloride. In the immediate postoperative period, the patient's temperature and pulse rate rose sharply and hypotension became severe, despite adequate blood, fluid, and electrolyte therapy, as shown in figures 1 and 2.

On the first postoperative day unexplained progressive hypotension persisted even with the administration of concentrated arterenol solution. The patient's appearance and color were excellent. She was rational and alert and had no pain or blood loss. Urine output was excellent. Digitalis and oxygen were given for their possible supportive value to the heart, although there was no cyanosis present.

By the third postoperative day, hypotension was severe and the blood pressure was labile. The patient was somewhat confused and had intermittent coldness of the extremities. There was hemoconcentration and marked increase in blood

Read before the general session, seventh annual combined meeting, New Hampshire and Vermont State Medical Societies, Portsmouth, N. H., Oct. 8, 1956.

viscosity. Arterenol was given continuously, but it was ineffective. An electrocardiogram showed evidence of myocardial ischemia.

The clinical picture suggested adrenal cortical insufficiency, and a total of 250 mg. of hydrocortisone was given intravenously on the third postoperative day. A few minutes after the first dose of 100 mg. of hydrocortisone the blood pressure rose sharply and then gradually stabilized. Subsequently there was rapid improvement in the patient's condition.

On the fourth postoperative day a total of 200 mg. of hydrocortisone was administered intravenously. The patient's blood pressure continued to approach normal. No arterenol was required. The pulse rate, temperature, and hemoconcentration declined. By the 11th postoperative day the patient was fully ambulatory, and the wound was healing well. She went home on the 14th postoperative day.

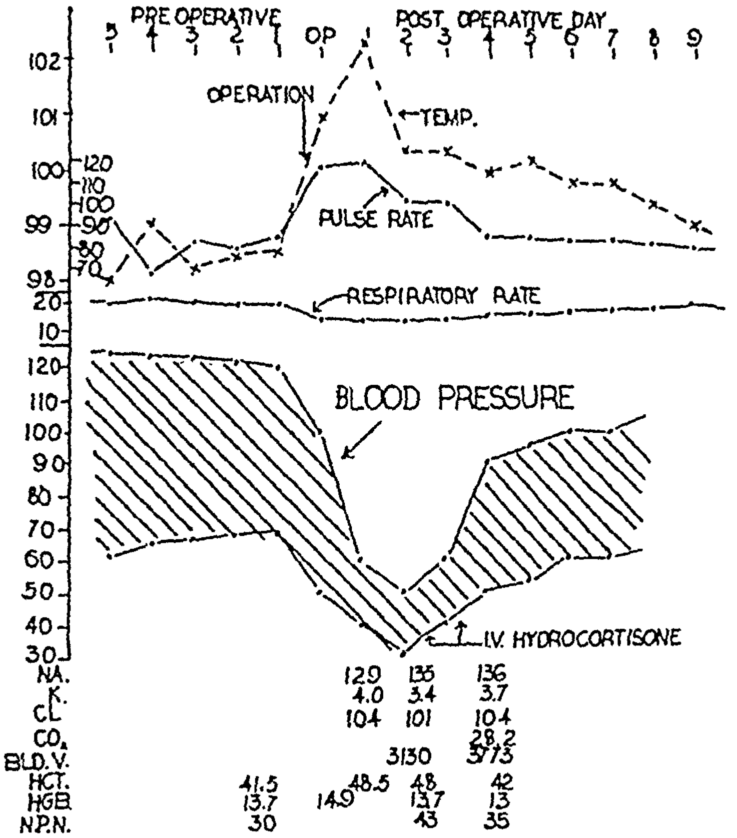

Fig. 1.—Chart showing rise in patient's temperature and pulse rate and lowering of blood pressure during postoperative period, with subsequent rise in blood pressure after intravenous administration of hydrocortisone. At bottom of chart are given values of such blood constituents as sodium, potassium, chloride, and nonprotein nitrogen, as well as the blood volume (in milliliters), carbon dioxide-combining power (in volumes per cent), hemoglobin level (in grams per 100 ml.), and hematocrit reading (in percentage).

Four other cases have been seen at this hospital, of similar type although less dramatic in detail. In each the problem was one of severe hypotension, unexplained by any of the ordinary causes of shock and unresponsive to the usually effective therapeutic measures. Sodium loss specifically was not a cause in any one of the cases.

Comment

A review of case data at the Memorial Center for Cancer and Allied Diseases, New York, indicated that approximately 1 out of every 300 patients subjected to surgery exhibited some form of adrenal cortical insufficiency. The effect of preoperative medication, anesthetization, and operation on the development of postoperative adrenal insufficiency has been suggested by the studies of Schwartz and co-workers[4] on patients with adrenal cortical hypofunction. It appeared that no one drug or method of administering an anesthetic was without harmful effect. Complications occurred proportionately and as frequently with each o the ordinary medicaments and anesthetic agents used It was also noted that evidence of adrenal cortical in sufficiency might develop during any type of opera tion, including minor procedures. Schwartz and h co-authors recommended that premedication be mi imal in dosage. They commented that agents whic may produce significant hypotension, such as spin anesthesia, tribromoethanol (Avertin), and deep i halation anesthesia, are inadvisable and warned th an alert watch must be kept to avoid hemorrhage ar excessive trauma.

A history of prolonged reaction time from anesth sia or the appearance of marked hypotension duri *previous operations should arouse suspicions of inad* quate function of the adrenal cortex. Decreased t erance to *stress is found more frequently in the old* age group and *in the debilitated patent who has h* repeated operative procedures.[5] *Also, there is a ne* for *increased cortisone therapy* during any form *stress, including surgery in patients with* adrenal cor cal hypofunction *and those who have undergone adre* alectomy, and in those patients who are receiving who have received cortisone *for other condition.*[6]

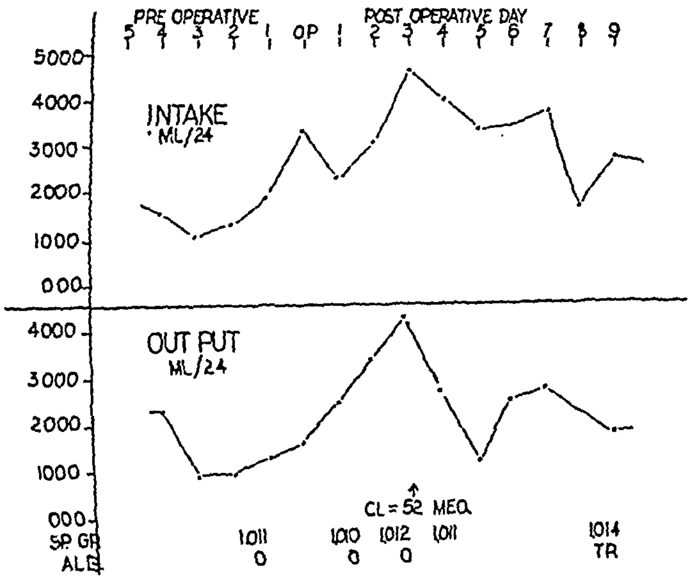

Fig. 2.—Chart showing volume of fluid intake and output (in milliliters per 24 hours) of patient with acute adrenal cortical insufficiency. Under output there are also given such urinary findings as specific gravity amounts albumin. Red blood cell casts were present in the urine on the first, third, and eighth days after operation.

Previous adrenal disease, such as infection (especially meningococcemia or staphylococcemia and tuberculosis), neoplasm, or idiopathic atrophy may result in latent chronic adrenal cortical insufficiency; with the development of adrenal crisis during stressful situations. Secondary adrenal cortical insufficiency as a result of pituitary hypofunction is almost invariably as-ated with other anterior pituitary hormone deficies and is more commonly recognized prior to ery.

ersistent hypotension during surgery or in the imliate postoperative period is the most significant of the development of adrenal cortical insufficien- The picture is that of severe vascular collapse, a failure to respond to adequate blood, fluid, and trolyte therapy and vasoconstrictor agents. The mpt favorable response to intravenously adminisd hydrocortisone suggests that the basic physiologidisturbance is a deficiency of adrenal cortical secre. The degree of azotemia, hemoconcentration, and uced blood volume[8] have been used as indexes of the erity of adrenal cortical insufficiency in adrenalectoed animals and may be similarly useful in man.

t now appears that the intravenous administration corticotropin (ACTH), with the determination of levels of 17-hydroxycorticosteroids and 17-ketoiods in blood or urine, provides the most accurate ns of quantitating adrenal cortical response to itary stimulation.[9] It has been estimated that the put of hydrocortisone by the adrenal cortex during stress of surgery and anesthetization normally is roximately 50 to 100 mg. the first day, gradually reasing to the normal output of 25 to 30 mg. in ut five to seven days.[10]

ecently, Perlmutter[11] has proposed a rapid test for enal cortical insufficiency useful in the postoperative ck state. As a result of the intensive postoperative enal cortical activity, the renal tubules normally orb most of the sodium from the glomerular filtrate, s causing a marked decrease in urinary sodium contration. When adrenal cortical or renal tubular inficiency is present, sodium output remains relatively h and serum sodium is decreased. The failure of an reased ratio between urine uric acid and creatinine the first 24 postoperative hours has also been used evidence of adrenal cortical insufficiency.[12]

atients operated on for various diseases with an ventful postoperative course have a maximal dease in circulating eosinophils on the first and second toperative days, followed by an increase surpassing initial level up to the seventh postoperative day. ler patients show a more pronounced eosinophil dession and a delayed eosinophil recovery.[13] The inophil response to epinephrine is without much ue as a measure of adrenal cortical activity, since administration of adequate doses of epinephrine been shown to produce eosinopenia even in the ence of adrenal cortical tissue.

ipsett and Pearson[14] have recently emphasized t the clinical situation of adrenal crisis is a synthesis two distinct syndromes, that of sodium loss and that deficiency of adrenal hydrocortisone. Therapeutily, it is important to distinguish between sodium detion, deficiency of 17-hydroxycorticosteroids, and a nbination of the two.

he mechanism of the effective action of hydrotisone therapy in subclinical adrenal insufficiency unknown. It appears that the capacity of cortisone to increase arterial pressure is accentuated in the presence of renal damage and states of adrenal insufficiency. The administration of cortisone alone has been demonstrated to be capable of correcting peripheral vascular failure encountered in acute adrenal insufficiency.[15] Cortisone probably increases capillary resistence[16] and may be necessary to maintain the tone of the terminal vascular bed. In addition, adrenal cortical extracts have been shown to potentiate the action of vasoconstrictors on blood vessels.[17] It may be, therefore, that cortisone has a potentiating effect on vasoconstrictor agents as well as a direct action on peripheral blood vessels.

Effective management depends on recognition of the problem of adrenal cortisone insufficiency. A preoperative test of adrenal response to stress should be made in patients who have exhibited previous surgical hypotension or prolonged reaction time to anesthetization; this test should also be made in the elderly debilitated patient and in those who have had repeated operations. Patients who have received cortisone in the past or who are receiving cortisone currently must be managed with a well-planned preoperative and postoperative regimen of increased cortisone therapy to support them through the period of increased stress.

The cornerstone of treatment is the administration of adequate amounts of cortisone or hydrocortisone. The assumption is never warranted that the clinical syndrome is due solely to salt loss.[14] In addition to adequate therapy with blood, fluids, and electrolytes, intravenously given hydrocortisone results in a dramatic rise and stabilization of the blood pressure and marked improvement of the patient's condition. The administration of hydrocortisone intravenously should be such as to maintain a high level of circulating hormone for several days, followed by a gradual reduction to maintenance levels.

Two possible dangers must be considered when cortisone or hydrocortisone is used for short-term, intensive therapy. Since cortisone and hydrocortisone increase the excitability of the central nervous system, epileptic seizures or psychotic reactions may be precipitated in susceptible patients. Another possible danger is that of excessive sodium retention and the development of edema produced by a high sodium intake during the intravenous administration of hydrocortisone.[10]

Summary

Acute adrenal cortical insufficiency may be an important factor in postoperative shock which does not respond to the usual measures of adequate blood, fluids, electrolytes, and vasopressor agents. Persistent hypotension during surgery or in the immediate postoperative period is the most significant sign of the development of adrenal cortical insufficiency. Effective management depends upon the recognition of this clinical condition and its favorable response to hydrocortisone therapy.

NONABSORBABLE WATER-SOLUBLE CONTRAST MEDIUMS

THEIR USE IN DIAGNOSIS OF INTESTINAL OBSTRUCTION

Bernard S. Epstein, M.D., New Hyde Park, N. Y.

/ The interpretation of scout abdominal roentgenograms for intestinal obstruction depends chiefly on evaluation of intraluminal gas and fluid patterns. All too often it is assumed that this diagnosis is arrived at easily when gas and fluid levels or ladder patterns of distention are present in the small intestine. However, the difficulties and shortcomings inherent in this examination often are underestimated.

Opinion as to the use of barium sulfate suspensions for examinations of the small intestine when intestinal obstruction is suspected still is divided. Generally such examinations are considered hazardous when a complete or strangulating obstruction exists. The danger is regarded as less when there is only partial obstruction of the small intestine, provided that the colon is clear. Difficulty also may arise in the differentiation of distended loops of small intestine from dilated colon, particularly the transverse colon. Sometimes neither the configuration nor position of the distended loops permits their anatomic identification.

Recently, the oral administration of water-sol substances commonly used for intravenous urogra and angiocardiography has been suggested for gas intestinal examinations.[1] These substances are n toxic, cannot solidify, and are unabsorbable from gastrointestinal tract. I have used diatrizoate (paque) sodium in dilutions varying from 30 to and Renografin (a mixture of the sodium and met glucamine salts of diatrizoate) in strengths var from 30 to 76%.) On request, diatrizoate was m available by its manufacturers in powder form an bulk solution, which may be diluted and flavore desired. Renografin was later supplied in bulk sterile 60% solution for oral use. The main advan of these preparations is lower cost.

In normal adults, good opacification of the stom duodenum, and upper jejunum can be obtained w solutions of either contrast medium in dilutions from 50 to 90% (see figure, parts *A* and *B*). Wea solutions are adequate for people of slight stature for children. Good portrayal of the mucosal folds the duodenum and proximal jejunum is obtained, the mucosal pattern of the distal two-thirds of the jejunum and of the ileum often is indistinct. This

abdominal roentgenogram, with patient supine, 15 minutes after oral ingestion of 60 cc. of 90% diatrizoate (Hypaque) so- . Stomach, duodenum, and jejunum are well outlined, and some of contrast material has reached the ileum. *B*, film made one after oral ingestion of 90 cc. of 75% diatrizoate in another normal adult patient. Stomach contains considerable amount of rast medium, although small intestine and colon have been traversed. This illustrates rapid transit time usually seen. Note lack arpness of mucosal pattern of small intestine. *C*, abdominal roentgenogram, with patient supine, one hour after oral ingestion cc. of 76% Renografin in patient with ileus secondary to acute ulcerative colitis. Contrast medium has collected and remained stric fundus. *D*, roentgenogram, with patient supine, showing distention of small intestinal loops in midabdomen of 70-year-old an with abdominal distention and vomiting for two days. This was interpreted as consistent with obstruction in ileum. *E*, same nt 15 minutes after administration of 60 cc. of 76% Renografin through Levin tube. Distended loops are jejunal. *F*, same pa- after four hours. Contrast medium still is mainly in jejunum, but some has entered ileum and ascending colon. This was osed as partial obstruction. At operation, distal jejunum was adherent to and kinked against sigmoid by firm adhesions. nteroposterior roentgenogram three hours after oral ingestion of 60 cc. of 70% diatrizoate. Note distended jejunum, indicating al obstruction. Narrowed segment is seen low in pelvis to left of midline (arrow). *H*, same patient, 24-hour film. Small intes- *is* empty, and contrast medium is in colon. *I*, same patient, four days later. Three-hour film after barium meal. Note stenotic in pelvis. This patient, a 48-year-old woman, had partial obstruction due to peritoneal metastases from omental sarcoma.

attributed to the hygroscopic quality of the contrast medium. The normal transit time of these substances through the small intestine is from 30 to 90 minutes. It is not uncommon to find the contrast medium in the stomach, the entire small intestine, and the colon within the same hour.

If the clinical picture suggests the possibility of obstruction of the small intestine and plain roentgenograms show an equivocal pattern of intestinal distention, information about the size and location of the various intestinal loops may be obtained by the use of these water-soluble materials without danger or inconvenience to the patient other than the distaste of swallowing a rather acrid medicine. The main purpose of this procedure is to help determine the location and extent of an obstructive process.

Oral administration of from 30 to 90 cc. of an adequate concentration of either diatrizoate or Renografin has proved helpful. With bedridden patients, it is important to move the patient about to make sure that the contrast medium does not collect and remain in the fundus of the stomach. If this cannot be overcome, the contrast medium may have to be instilled through a duodenal tube. When adequate passage through the duodenum is observed, it is quickly possible to identify the position, caliber, and rate of passage of the contrast medium through the small intestine. Subsequent films made at appropriate intervals serve to delineate the intestinal loops, which become partly opacified as the contrast medium traverses them.

This procedure was employed in 10 cases in which the clinical picture and the scout roentgenograms suggested the presence of either obstruction of the small intestine or ileus after operation (see figure, part *C*). The surgical procedures had been laparotomies for ovarian carcinoma, pancreatic carcinoma, ulcerative colitis, regional enteritis, and carcinoma of the ascending colon. The contrast medium traversed the small intestine within 90 minutes in these patients, eliminating the possibility that there was any significant degree of obstruction. Conservative treatment for ileus was effective.

There were four postoperative patients in whom the presence of obstruction of the small intestine due to adhesive bands was considered probable (see figure, parts *D*, *E*, and *F*). In these the opaque medium was retained in loops of jejunum and proximal ileum for four hours or longer. Subsequent films at 12 hours showed some of the contrast material in the colon, while the distention of the small intestinal loops persisted. In these partial obstruction was diagnosed. In three, conservative treatment was elected even though equally competent observers differed in their opinion as to whether operation was indicated. Reoperation was considered necessary in one patient five days after operation, and several bands partially occluding the distal ileum were severed. In this patient the contrast material traversed the small intestine slowly. Retention of some in the ileum over a 24-hour period suggested a partial obstruction.

In two cases, partial small intestinal obstructio was attributed to peritoneal carcinomatosis fro ovarian malignancies, and in one a similar process w due to spread from an omental sarcoma. Scout fil of the abdomen showed distention of the small i testine with numerous fluid levels. There was co siderable delay in the passage of the opaque mediu through the small intestine, indicating partial obstru tion. In the third patient (see figure, parts *G*, *H*, a *I*), a narrowed loop of small intestine was visible the left of the midline in the pelvis. This was c sidered the obstructive site. After six hours the c trast medium appeared in the colon. Because of t it was considered safe to repeat the examination w barium. Again there was delay in the transit of contrast material, but several areas of stricture co be clearly identified, better than with the water-solu substances. This suggested that diatrizoate or Re grafin be used for preliminary studies and that m definitive examinations with barium can be done w necessary.

Two cases of carcinoma of the cecum presented partial obstructions at the ileocecal valve. In b there was sufficient opacification of the cecum to id tify the lesion. The obstruction of the small intest was considered partial because some of the cont material entered the colon after six hours. One pati responded temporarily to intubation. The lesion overlooked, and obstruction recurred about two we later. The diagnosis of cecal carcinoma was confir at operation. In the second case there was mar distention of the entire small intestine. The ileoce junction was narrowed and tapered. At operation t was found to be due to infiltration of the ileocecal valve with tumor.

Water-soluble substances may also be used for examinations of the colon when there is question as to advisability of using barium. Such doubt may arise in patients with intussusception or where the possibility of perforation of the intestine or prolonged retention of contrast material is anticipated.

Summary

Water-soluble contrast mediums used for intravenous urography or angiocardiography may be helpful in the examination of the small intestine when the use of barium sulfate suspensions is considered hazardous. These may be regarded as preliminary studies and may be followed by barium examinations if patency of the intestine is established.

270-05 76th Ave.

The diatrizoate sodium used in this study was supplied as Hypaque sodium by the Medical Research Department of Winthrop-Stearns, Inc., New York, and the Renografin by the Squibb Institute for Medical Research, New Brunswick, N. J.

APPARENT INCREASE IN FREQUENCY OF INFECTIONS INVOLVING TORULOPSIS GLABRATA

PROCEDURE FOR ITS IDENTIFICATION

Lynferd J. Wickerham, Ph.D., Peoria, Ill.

Occasionally, rare yeasts of medical significance are ent to me for identification. Among these have been hree strains of Torulopsis glabrata (Anderson) Lod-er and De Vries in the years 1938 to 1956. Since Iarch, 1956, six additional strains of this species have een received, all from human patients including two with yeast septicemia. The well-known increase in in-ection caused by Candida albicans following the ex-ensive use of antibiotics[1] suggests a possible similar elationship between infection by T. glabrata and the use of antibiotics. The object of this report is to de-cribe how this species can be recognized. When it can be identified with certainty by medical technicians, all failures and successes in treatment of patients infected by it can be referred to a definite name rather than being accredited to an unknown yeast or, worse yet, to the wrong species. At present the yeast is so little known that it is not mentioned in the more prominent books on medical mycology. T. glabrata has remained almost unknown because it is much less common than the Candida species found on or in the body, and its ability to cause disease in laboratory animals is marginal.

Black and Fisher[2] isolated T. glabrata from a patient who had bronchopneumonia. The yeast was inoculated intraperitoneally into rats. The rats were killed after 5 to 10 days, and the yeast was cultivated from some of the organs. In both rats the omentum was contracted into a hard mass and contained some hard nodules. López Fernández,[3] in an article containing many photographs, reported on the pathogenicity of several strains of T. glabrata. Rabbits, guinea pigs, rats, and white mice were used, the mice being more sensitive and giving a more complete histopathological picture. Intravenous and intraperitoneal inoculations gave the most constant results. The most characteristic feature was the formation of nodular lesions with an intense elaboration of reticuloendothelial cells. The yeast cells were localized within the macrophages, to give a histopathological aspect which López Fernández stated was identical to that found in histoplasmosis.

Lodder and De Vries[4] injected intracardially five strains of T. glabrata from human sources into five rats each. Three of the five inoculated from one of the strains died in about three months. Two other rats died also, each having received injection of a different strain of yeast. The yeasts were isolated from the lungs of the dead rats. Lodder and De Minjer[5] injected T. glabrata into a number of mice and rats intraperitoneally and subcutaneously. No pathological changes could be observed in these animals, and yeast cells were never found in any of their organs. Lodder and De Minjer concluded that this strain was not pathogenic. There are good reasons for believing that all of the preceding papers were based on studies of authentic strains.

The results of tests in animals are certainly not the final indication of a strain's pathogenicity in humans when the results are weak and variable, but the recurrence of characteristic pathology after injection with some strains is strongly suggestive. The repeated isolation of the yeast in cases of septicemia in humans is strongly indicative, and over 60 positive cultures have been made from the blood of one patient. Just as the common use of antibiotics has increased the incidence and seriousness of infection by the very commonly carried C. albicans, so an increased incidence of human infection by the more marginally pathogenic species, T. glabrata and C. tropicalis, might be anticipated. Stovall and Pessin[6] have demonstrated that 5 to 15 times as many cells of C. tropicalis as of C. albicans are required to cause death in rabbits; and Seligmann[7] showed that a strain of C. albicans which was nonpathogenic for mice became lethal when cells were accompanied by 2 mg. of aureomycin. It should be of interest for someone to test the pathogenicity of T. glabrata and C. tropicalis accompanied by antibiotics.

Differentiation of Yeast Species

The following notations regarding the identification of fermentative yeasts that are more or less commonly found on or in the human body are given from the viewpoint of one who has worked with pathogens to a considerable extent but who has been concerned with the taxonomy of all yeasts to a greater extent. Three of the species in the table are of special interest: C. albicans, which is definitely known to cause disease, and T. glabrata and C. tropicalis, which are thought to be marginal pathogens. Sufficient information will be given concerning these three to permit their separation from all other species that might be expected on or in the human body.

I routinely use 38 carbon sources for the identification of yeasts, of which five were selected for the table. As few of the yeasts studied are pathogens, an incubation temperature of 25 C is used for a period of 20 to 24 days. The assimilation reactions are less variable than fermentation reactions, and only 0.5% of carbohydrate is required as compared with 2% for all fermentation tests except with the sugar raffinose, which requires 4%. Cornmeal agar or other mediums used for enhancing the development of hyphae may be used for colonies or dalmau preparations. The latter

---

permit the direct microscopic observation of cultures growing in plates or on agar-coated slides. I have described the morphologic and physiological procedures mentioned here elsewhere.[8]

C. krusei at four to six days' incubation on commonly used mediums produces colonies which usually show hyphal tips in the moderately crowded portion of the Petri plate when the plate is held to the light with the bottom of the plate toward the observer. Large cells are present microscopically. This species ferments glucose strongly but has no action on trehalose. C. krusei is a very common saprophyte.

T. glabrata produces colonies which are smooth and show no hyphal tips. It causes gaseous fermentation of glucose and trehalose. No other species of yeast is known which ferments these sugars and does not assimilate maltose, sucrose, and cellobiose. T. glabrata is very rarely isolated from sources other than the human body. It is most commonly found in the urinary, intestinal, and respiratory systems but it is not found in the central nervous system. It is much more closely related to the Candida species discussed immediately below than to Cryptococcus.

*Diagnostic Reaction of Yeasts Which Produce Gaseous Fermentation of One or More Sugars and Are More or Less Commonly Associated with Human Body**

	Carbon Assimilation					Fermentation

* + Means growth where it refers to assimilation, gas where is refers to fermentation; V means variable;—means no growth where reference is to assimilation, no gas where reference is to fermentation.

† Raffinose ⅓ indicated that hydrolysis proceeds only to the melibiose stage.

C. parapsilosis, C. (Endomycopsis) guilliermondii, C. albicans, and C. tropicalis occur close together taxonomically in the same phylogenetic line of species. C. albicans and C. tropicalis strains generally produce hyphae quite noticeably, C. parapsilosis and C. guilliermondii to a lesser extent. C. albicans and C. tropicalis are immediately distinguished by their fermentation reactions. C. albicans and its variety stellatoidea is the only species associated with the animal body that produces a gaseous fermentation of maltose and not of sucrose; it also is the only yeast found there which produces chlamydospores. C. tropicalis is almost unique in producing a gaseous fermentation of sucrose and an alkaline reaction in raffinose. Rare strains of Saccharomyces also have this combination of reactions on sucrose and raffinose, but they are very different from C. tropicalis in carbon assimilation reactions and they have not been reported from the animal body.

C. parapsilosis and C. guilliermondii show no defini difference in the table presented here, but nearly a strains of C. guilliermondii ferment sucrose, wherea no strains of C. parapsilosis do. The two species diffe in their ability to assimilate cellobiose and raffinose, C. parapsilosis assimilating neither and C. guilliermondi assimilating both. C. guilliermondii has a rather wid range of variation. It is possible that a further stud of mating type reactions[9] and biochemistry will sho that C. guilliermondii is presently composed of mor than one species. C. guilliermondii and C. parapsilosi are most commonly found in association with trees and in soil; C. tropicalis is common in soil and occasionall occurs in the respiratory tract, and C. albicans is almost exclusively found in the animal body.

C. (Torulopsis) utilis is a rare yeast usually found associated with the animal body or in plants producing bakers' yeast. It is readily differentiated from the other fermentative species in the table by its carbon assimilation reactions and by its ability to assimilat nitrate. Saccharomyces cerevisiae has been isolate from the vagina of diabetics and from lungs an mouths of patients. S. fragilis and its imperfect form C. pseudotropicalis, are occasionally isolated from th body and are the only lactose-fermenting species foun there. Cryptococcus neoformans and related specie are differentiated from all of the preceding by thei ability to synthesize starch and inability to cause gaseous fermentation of sugars.

Summary

There is some indication that Torulopsis glabrat previously considered to be slightly pathogenic (nonpathogenic, is now becoming more common an may in some cases cause serious infections. This pape is written to alert physicians to its occurrence and t inform technicians regarding its identification.

COUNCIL ON FOODS AND NUTRITION

SYMPOSIUM ON NUTRITION IN PREGNANCY

The following announcement has been authorized by the Council on Foods and Nutrition.

Philip L. White, Sc.D., *Secretary.*

A symposium "Nutrition in Pregnancy" will be held in Columbia, Mo., Oct. 11, 1957. This symposium will be sponsored by the Council on Foods and Nutrition with the cooperation of Boone County Medical Society; School of Medicine, University of Missouri; and Adult Education and Extension Service, University of Missouri.

The program, which will begin at 8 a.m. Friday, Oct. 11, will be held in the auditorium of the University of Missouri Medical Center. The meeting will be open to all interested persons, and there will be no registration fee.

The following program has been arranged:

Morning Session

8:00 a.m. Registration.

9:00 a.m. Influence of Maternal Nutritional Level on the Fetus and Infant. Dr. Ray Hepner, Associate Professor of Pediatrics, University of Missouri Medical Center.

9:30 a.m. Metabolic and Biochemical Changes in Normal Pregnancy. Dr. Icie Macy Hoobler, Consultant, Merrill-Palmer School, Detroit; Former Director, Research Laboratory, Children's Fund of Michigan.

10:30 a.m. Importance of Nutritional State of Mother Prior to Conception. Dr. Genevieve Stearns, Research Professor of Orthopedics, State University of Iowa.

11:15 a.m. Nutrition Experiments as an Instrument of Teratologic Research. Dr. Joseph Warkany, Professor of Pediatrics, University of Cincinnati.

Discussion: Dr. Albert G. Hogan, Professor Emeritus of Animal Nutrition, University of Missouri.

Afternoon Session

2:00 p.m. The Effect of the Reproductive Cycle on Nutritional Status and Requirements. Dr. William J. McGanity, Associate Professor of Obstetrics and Gynecology, Vanderbilt University, Nashville, Tenn.

2:45 p.m. Dietary Habits During Pregnancy. Miss Dorothy Vorhies, Associate Professor of Dietetics; Mrs. Barbara Birmingham, Nutritionist, Outpatient Department, University of Missouri Medical Center.

3:30 p.m. Panel Discussion to Review Epidemiologic Studies.

Moderator: Dr. Icie Macy Hoobler.

Participants: Dr. Samuel B. Kirkwood, Clinical Professor of Obstetrics, Department of Maternal and Child Health, Harvard University School of Public Health; Commissioner, Department of Public Health, Commonwealth of Massachusetts. Dr. William J. Darby, Professor of Biochemistry, Vanderbilt University School of Medicine. Miss Marjorie Heseltine, Chief, Nutrition Section, Division of Health Services, Department of Health, Education, and Welfare. Drs. Hepner, McGanity, and Stearns.

MEDICINE AT WORK

WORLD MEDICINE COMES OF AGE

FEARLESS CONCERN FOR PATIENT IS HIGH POINT OF HARMONY IN VOICES OF 700,000 DOCTORS

Milton Golin

Cuban police seize physicians as hostages. A "flu" epidemic finds the Philippine Medical Association in desperate need of drugs. Maltese doctors are threatened when they resist a move to limit patients' free choice of physician. . . .

These recent crises carry a direct threat to the general public, not to the medical profession alone. Ten years ago, doctors of each nation usually had to slug out such problems themselves. More likely than not, there was no place outside their borders to turn for help—no voice to bespeak their troubles or to forewarn their colleagues in other lands. Massive danger to health and medical practice was only part of the handicap to physicians and their patients 10 years ago. Doctors needed to know what scientific developments in Berne, Switzerland, could benefit clinical knowledge in Kansas City, or what new medical education precept discussed in Vienna might raise the proficiency level of an intern or a budding specialist in Melbourne.

Today medicine has an international voice, the World Medical Association, a confederation of 53 national medical associations representing more than 700,000 physicians around the globe. It is sounding an alarm against those who would oppress the doctor and his patient. It is telling the story of far-flung advances in medical science. It is rallying help for brother physicians who are in need.

Help was needed urgently last Memorial Day as Asian (Far Eastern) influenza was striking hundreds of thousands of Filipinos. Physicians were running out of antipyretics. Off went a frantic cable from the Philippine Medical Association to the World Medical

Association headquarters in New York City: "Request immediate airlifting of antipyretics, analgesics and if available polyvalent flu vaccine." The cable could not have arrived at a more difficult time. A long holiday week end loomed ahead, and many pharmaceutical firms either were closed or were operating with only stand-by staffs. Air transportation companies had their own priority problems. There was the prospect, too, of governmental red tape in an international drug shipment.

But WMA's secretary-general, Dr. Louis H. Bauer, and his staff tackled the problem with know-how. First they notified the Civil Aeronautics Board, and the red tape began disappearing. Then they found that officials of the Borroughs Wellcome & Company, Inc., of Tuckahoe, N. Y., were able to prepare a 300-lb. shipment of an antipyretic analgesic for delivery to Newark airport before 5 p. m. that day. From there, a Flying Tiger cargo plane rushed the supply to San Francisco, where a Pan American Airways plane was waiting to carry it the rest of the way. On Sunday morning, before the end of the holiday week end, the drugs were delivered to eager medical hands in Manila. The accomplishment was speedy, spontaneous, and completely voluntary.

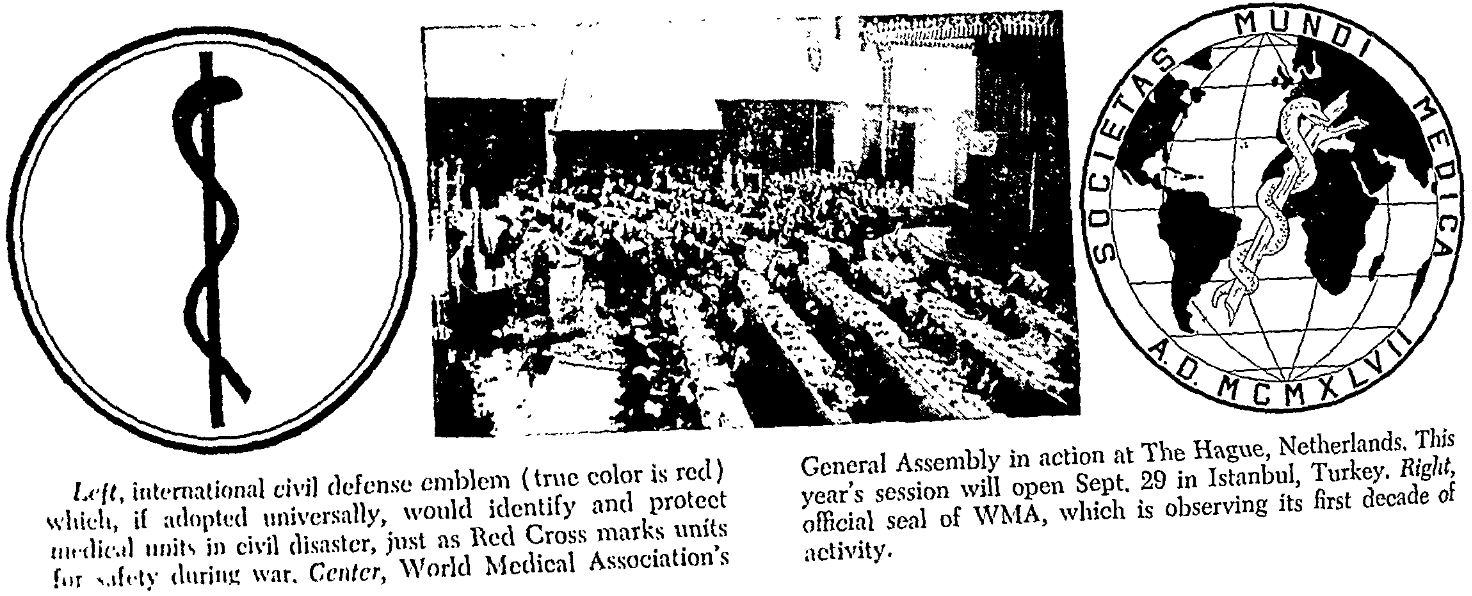
Within hours, other pharmaceutical firms were responding: A 600-lb. air shipment of analgesic from McNeil Laboratories; similar supplies arranged by E. R. Squibb & Sons; antibiotics and tranquilizers from Charles Pfizer & Company, Inc. Eli Lilly & Company launched a "crash" week-end project in their Indianapolis laboratories, in hopes of more quickly proving the effectiveness of their influenza vaccine. And Parke, Davis & Company authorized the Philippine Medical Association to obtain all necessary drugs from the company's Manila office. Said Dr. Bauer: "It is in the unity of purpose in such emergencies that the strength of the members of the health profession is tested—and proved equal to the task. It gives and does not count the cost; toils without resting; and asks no reward for its labor than a better and happier world for all people."

Help for Hungarians

Scores of Hungarian physicians certainly were asking no reward when they fled Communist butchery last fall. Many of them escaped so hurriedly that they left behind the vital papers which could show their accreditation. One of them reported: "I treated the children and youths injured in the rebellion. There was no time to fill in and file the numerous reports that the government required—nor did I feel justified in revealing the names, addresses, and conditions of the patients who came to me. . . . I was still in my clinic after midnight when a patient's mother came to warn me that the police were on their way to arrest me for treason. I fled. . . . I have no papers to prove who I am or what my education and experience has been—life, security, and freedom for my family were my only thought."

This doctor's plight illustrates a major project of the World Medical Association: A central repository for medical credentials (carrying the registrant's dated photograph, fingerprints, and notarized signature) so that physicians everywhere can prove their qualifications in case disaster strikes at their home country. "Success in this one program alone," says Dr. Bauer, "would justify the existence of WMA." For lack of such a repository, meanwhile, the WMA has been trying to establish new credentials for, and otherwise rehabilitate, Hungarian refugee physicians in the free medical world.

The WMA first spoke out against the Hungarian outrage last November in a telegram to the United Nations, strongly urging "that every necessary step be taken to prevent further butchery and deportation of Hungarian citizens and that the actions of those responsible for these atrocities be strongly condemned." Soon afterward, the U. N. did just that—censured perpetrators of the terrorism. Next came WMA's appeal to member associations and individual physicians that "all possible aid to Hungary through your organization . . . will be another proof of the importance the doctors of the world place on human dignity and freedom."



Left, international civil defense emblem (true color is red) which, if adopted universally, would identify and protect medical units in civil disaster, just as Red Cross marks units for safety during war. *Center*, World Medical Association's General Assembly in action at The Hague, Netherlands. This year's session will open Sept. 29 in Istanbul, Turkey. *Right*, official seal of WMA, which is observing its first decade of activity.

Mature Voice of Medicine

This is the voice of world medicine, come of age, a voice with authoritative tone. WMA's cry against oppression in Hungary is the mature call of a young adult born out of the ferment of World War II. Doctors from many nations were thrown together in the common missions of that great conflict over a decade ago. Their wartime brotherhood in arms suggested the values of a permanent international alliance of organized medicine. These physicians also felt the need to restate medicine's universality, and to express their independence of political compulsions. There was a need, too, to assert a solidarity in repudiating the perverted medical practices which were forced against some physicians in Nazi concentration camps. (Based on a 1948 "Declaration of Geneva," WMA physicians pledge: "I will retain the utmost respect for human life from the time of conception; even under threat I will not use my knowledge contrary to the laws of humanity.")

In this background will the World Medical Association observe its 10th birthday on Sept. 18. When the WMA speaks today, it is heard as the official voice of the practicing profession, listened to by such diverse global agencies as the International Labour Office, International Social Security Association, and World Health Organization. And when WMA spoke out for help for Hungary's refugee doctors (sending 500 Swiss francs as a starter) it spawned offers of additional funds, medical supplies and aid, housing accommodations, and resettlement facilities from medical associations in the United States, Austria, Chile, Finland, Denmark, Cuba, and other nations.

Crisis in Cuba

The Cuban contribution, particularly, carries an ironic note. Even today, less than a year after the last WMA general assembly in Havana, Cuban physicians are being persecuted because they, like their Hungarian colleagues, gave medical treatment to those demonstrating against the government. Last June the Cuban Medical Association offices were raided during a regular business session. Physicians who care for sick and wounded "street rebels" still are being beaten, imprisoned and held as hostages. It is a criminal offense for the medical association to hold meetings.

The crisis in Cuba is scheduled for discussion at Istanbul, Turkey, starting Sept. 29 when WMA President J. A. Bustamante, himself a Cuban physician, opens the next general assembly under a theme of "Solidarity—the Key to Medical Advance." The WMA already has pointed out that, while doctors must fulfill their duties as citizens, they are pledged to serve humanity—without regard to religion, nationality, race, social standing, or party politics. Not long ago the WMA announced that while it cannot "within the framework of its constitution engage in political conflicts . . . the doctors of Cuba need the moral support of every freedom-loving medical association." Since then, letters of encouragement have been arriving daily in Havana, Santiago, and other Cuban communities, reminding the doctors that colleagues in other lands are supporting them in all humanitarian efforts.

Belgium and Malta

Repeatedly, humanitarianism has shown its power in the climate of world medical opinion. In Belgium, the government time and again has tried to create a state medical service which would force doctors to abide by all past and future ministerial regulations, and would require patients to obtain a permit before seeking medical care. So the Belgian medical profession organized its own medical insurance plan to assure free choice of physician. Not only are Belgian doctors and patients satisfied, but physicians from other countries have acclaimed the plan. This spring, WMA Delegate Pierre Glorieux reported: "My [Belgian] government, recognizing that it could not control the medical profession, sent a new bill to the parliament which . . . would remove all aspects of social security from the legislative power of parliament. The prime minister has officially stated that he will respect all the conventions of the medical profession."

Not long ago the territorial government of Malta embarked on a campaign of threat, insult, and harassment in an effort to limit the private practice of medicine in favor of a salaried service. When the nearly 200 Maltese physicians resisted, the prime minister hinted that he would import physicians from abroad to carry out his plan. The WMA promptly alerted the profession in neighboring countries, and the result was a governmental agreement to put aside its plans. Again, international solidarity among physicians had upheld a measure of freedom for them and their patients. (Says the WMA: "Confidence in one's doctor is essential for good therapeutics, and a patient does not ordinarily have confidence in a doctor whom he is compelled to consult.")

In scattered regions of the world other physicians are gaining strength and moral support from the World Medical Association:

—The Venezuelan government revamps its social security bill in order to include a free choice of doctor for the patient, after the Venezuelan Medical Association points out that "the best interests of the people and the profession can only be served when the legislation conforms to the Twelve Principles of social security established by the World Medical Association."

—The Japanese Medical Association arouses physicians in scores of nations when it reports in the trilingual (English, Spanish, and French) *World Medical Journal*, official publication of the WMA, that government medicine methods threaten to restrict visits of Japanese patients to their doctors "in complete disregard of public opinion."

—Bolstered by WMA principles, the Chile medical profession has achieved a new unity in its three-year battle against restrictive government pressures.

Other Programs

It would be a mistake, judging from these events alone, to regard WMA as a lobby bent only on fighting the evils of socialized medicine. Other efforts outshine its role as an alarm-ringer and fighter for unfettered medical practice. One is the drive for a central repository for medical credentials. Another is sponsorship of the first World Conference on Medical Education, in London in 1953 (the second is set for 1959 in Chicago). The WMA also has adopted a modernized Hippocratic Oath, as well as an International Code of Ethics. Already successful in some South American countries, WMA is continuing to help in the establishment of national medical associations elsewhere throughout the world. Currently, it is:

—Promoting a freer international flow of proved therapeutic agents.

—Formulating principles of cooperation between practicing physicians and public health officers.

—Promoting medical research.

—Observing and reporting on the activities of more than 23 other international organizations as they affect the practice of medicine.

Another WMA project is universal adoption of a special emblem that will identify and protect medical units in civil defense—just as the Red Cross symbol protects units during armed conflict. The civil defense design (see figure) has been agreed upon by a joint committee of International Medicine and Pharmacy, the WMA, and the International Red Cross; it already is ratified by several nations.

Do Not Confuse WMA with WHO

WMA makes a point of distinguishing itself from the World Health Organization. WHO is strictly intergovernmental public health agency created by the United Nations and supported this year by member nations to the tune of $13,500,000. The World Medical Association, on the other hand, is completely nongovernmental in its origin of national medical associations. Operating this year on a budget of only $165,000 (little more than 1% of WHO's whopping expenditures), WMA is the voice of the practicing profession and the individual patient. During its first five years, WMA was pledged $250,000 by joint action of the American Medical Association Board of Trustees and representatives of the pharmaceutical industry. This placed the fledgling organization on sound footing. Since then, a United States Committee, and supporting groups of other nations—comprising individual physicians, laymen, and corporate members—have provided backbone support to WMA through dues ($10 annually per person in the U. S.) and voluntary activity.

One result of this individual participation is a stark awareness that what happens to the freedoms of 200 doctors and their patients on the Island of Malta, or in another part of the world, can affect the futures of doctors and patients everywhere. The U. S. Committee, approaching this year's membership goal of 10,000, thus is made up of physicians who have taken the lead in realizing that there is just as much need for boosting WMA as for taking part in county, state, and national medical society activities. They know that health is a language that can be spoken everywhere. Last spring, for example, some 3,000 physicians from 48 nations including the Soviet Union kicked over all barriers of communication when they took part in an annual International Congress of Otolaryngology in Washington, D. C. The atmosphere was amicable because they had a common interest.

Similar rapport in the health field is taking place this week in Rome, where an estimated attendance of 1,000 American dentists at the Federation Dentaire Internationale is furthering President Eisenhower's People-to-People Program. That program is being pursued not only by the U. S. Committee of the WMA but also by:

—Thousands of U. S. armed forces medical personnel who care for local populations overseas.

—American doctors who take part in demonstrations of new techniques during visits to hospitals and clinics abroad, as a means of stressing the desire of the United States to share its scientific progress.

—Pharmaceutical companies which emphasize international good will in their world-wide contacts. One—Smith, Kline & French—now has television production crews assigned to film activities of American physicians abroad in private, missionary, military, foundation, and government practice. Next February the firm will present the story as a documentary, portraying doctors as U. S. ambassadors of good will in Japan, Korea, Hong Kong, India, Indonesia, Iran, Turkey, Ethiopia, France, and Guatemala.

Instrument of Peace

As Dr. Albert C. Holt says in his hospital office in Bombay: "We are representing the whole medical profession in America to these people. . . . If we fail, American medicine has failed in their eyes."

Dr. Gunnar Gunderson, who is President-elect of the A. M. A., and also a director of WMA's United States Committee, puts it this way: "We can add new meaning to the M.D. degree—Medical Diplomacy. World peace cannot be attained until we build peace into the hearts and minds of men. Since physicians are the most intimately acquainted with the physical and mental needs of their patients, they are the most logical engineers for this great moral reconstruction project. If we more than half million physicians assume this task on an individual, personal basis we may yet succeed where soldiers, statesmen and politicians have previously failed."

ANTIBIOTICS IN VIRUS DISEASES

The threat of widespread virus disease in the form of Asian influenza makes it highly desirable to clarify thinking on the treatment of virus diseases. The Council on Drugs has prepared a statment, which appears elsewhere in this issue of THE JOURNAL, page 58, explaining the limitations of antibiotics in influenza and pointing out that their use in the primary treatment of this disease would be contrary to good medical practice. The principles involved, however, also apply to other virus diseases.

Evidence that thinking on the treatment of virus diseases has been confused can easily be gathered from conversations in public places, where it is not unusual to hear a person say, "I have a virus cold, and my doctor is giving me penicillin." There is also evidence to indicate that the misuse of antibiotics is not limited to the United States. Hennessen in Düsseldorf[1] reports that "the use of broad-spectrum antibiotics often begins before a diagnosis has been established." He shows that the action of antibiotics in disease differs radically from that of antiserums. An antiserum acts on a particular pathogenic organism or it does not act at all. If one excepts sensitization phenomena, it can be said that an antiserum which does no good at least does no harm.

Antibiotics, however, act differently. If the antibiotic in a given case encounters a resistant organism, its side-effects become in fact its only effects. This, says Hennessen, is the situation with all true virus diseases. With the exceptions of the large-particle viruses like trachoma and psittacosis, the viruses are resistant to the known antibiotics. As a result, medication with antibiotics in virus diseases violates the principle of *nil nocere*, for it is likely to result in substantial damage. A virus disease is a systemic infection. Its manifestations in various individual organs follow an actual viremia during which a patient's defense mechanisms must be considered as being under serious strain even if his symptoms are not alarming. At this stage the administration of chemotherapeutic drugs and antibiotics inevitably disturbs the physiological flora of his body, possibly to a grave extent.

Most of the organisms that normally populate the orifices and cavities of the body are sensitive to antibiotics; while these organisms tend to vanish under treatment with antibiotics, the orifices and cavities tend to become populated by organisms that are resistant and frequently pathogenic. There is hardly a clinic or hospital today, says Hennessen, that is not inhabited by therapy-resistant, pathogenic organisms. A superinfection by such nosocomial organisms therefore is actually favored whenever an antibiotic is used where it is not called for.

Various other circumstances conspire to increase this danger. Jensen[2] has reported the successive appearance of strains resistant to penicillin, to streptomycin, and to chlortetracycline when these antibiotics were being used preoperatively as prophylaxis against infections in thoracic surgery. Mikkelsen[3] reported similarly on attempts to use powerful antibiotics prophylactically before gastrointestinal surgery, especially in cancer patients. Micrococcic infections increased to an alarming extent. Whitlows and furuncles afflicted the nonmedical personnel of the hospital, and a 12-bed ward had to be evacuated because its occupants all developed abscesses. Kapp[4] similarly, after studying the effects of antibiotic prophylaxis in 250 patients undergoing so-called clean surgical procedures, found that such prophylaxis actually predisposed the patient to postoperative infectious complications. Hennessen points out that side-effects of antibiotics which are merely annoying in healthy people can be disastrous in the critically ill.

A real danger exists in the use of antibiotics in virus diseases, whether patients take antibiotic-containing remedies sold over the counter or whether physicians prescribe them before the proper diagnosis is made. The Special Committee on Influenza appointed by the Board of Trustees has stated that there is some degree of justification for using antibiotics when secondary bacterial infections follow the primary influenza infection, as they often do. The principles that should be followed in that case are outlined in the statement by the Council on Drugs. As regards the primary viral infection, however, experience indicates that the logical procedure is the development of a specific, preventive vaccine.

FITNESS OF AMERICAN YOUTH

In June, 1956, the President of the United States called a conference to deal with the fitness of American youth, a matter which had been called to his attention through publicity given to research based on certain alleged tests of physical fitness. This conference was held at the United States Naval Academy, Annapolis, Md., and was attended by approximately 150 invited participants, including physicians, athletes, coaches, educators, public health personnel, representatives of organizations interested in amateur and professional sports, representatives of mass publicity media and persons interested in recreation, the outdoors, and the general topic for which the conference was called. Dr. Elmer Hess and Dr. W. W. Bauer attended, invited as individuals. The proceedings of this conference have been published and single free copies are available from the American Medical Association, Bureau of Health Education (for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C., price 25 cents).

These proceedings reflect a broad, constructive, and sane attitude toward total fitness, embracing not only its physical but its mental, emotional, moral, and social aspects. They commend the work already being done and recommend that good work be encouraged and that no new agencies be established, particularly at the federal level. Where serious gaps exist, community cooperation is recommended with a maximum of encouragement to existing agencies for the expansion and enrichment of programs already in action.

The presiding officer of the conference, the Vice-President of the United States, stated in effect that the American people are not a nation of "softies" but that considerable improvement in fitness can and should be expected.

The medical profession welcomes this renewed interest in fitness stimulated by the President's conference and the subsequent actions of the President as recommended by the conference. By executive order on the same day that the conference met and reported, the President created at cabinet level a council on youth fitness, consisting of the Vice-President of the United States, chairman, and six cabinet officers (the Secretaries of Defense, Interior, Agriculture, Labor, and Health, Education and Welfare, and the Attorney General). He also implemented a second recommendation of the conference, namely that there be an advisory committee to the President's Council and that this committee be composed of outstanding citizens. Five doctors are included in its membership (Philip S. Barba, W. W. Bauer, Daniel Bergsma, Martha M. Eliot, Hans Kraus). The Committee is meeting at West Point, N. Y., September 9 and 10, 1957.

Almost immediately, a director was appointed for the President's Council on Youth Fitness; he is Shane MacCarthy, J.D., a political scientist and lecturer identified with the Central Intelligence Agency. His functions are to coordinate the work of the council and to encourage activities in youth fitness.

All this has a familiar sound to the medical profession. The early proceedings of the House of Delegates of the American Medical Association have shown an interest in the fitness of American youth since the Association's organization in 1847. This interest took concrete form with the organization in 1911 of a Joint Committee on Health Problems in Education in cooperation with the National Education Association. This committee remains active and influential to this date and has to its credit a large number of publications which have influenced child health, including three books which constitute a trilogy in school health (Health Education, School Health Services, Healthful School Living).

During World War II, the American Medical Association, at the invitation of the United States government, participated in a Joint Committee on Fitness. The activities of this committee were in high gear when the war came to an end and the government withdrew its membership on the committee, leaving an American Medical Association contingent of five members. The then President of the American Medical Association, Dr. R. L. Sensenich, requested the Bureau of Health Education to make suggestions for a continuation of the Association's interest in health and fitness of American youth. The bureau proposed a plan for concentrating on the health of the school-age child as a key population group through which the greatest impact on the fitness of American youth could be made with the smallest amount of expense and largely through existing organization channels. This service was established experimentally in 1947, and an educator and a physician were added to the staff of the bureau to initiate the work.

For 12 years, the consultants in school health, augmented in 1956 by a woman physical educator, have ranged the highways and the byways of the

United States giving aid, counsel, and cooperation in the development of statewide and local school health projects. Extensive improvements in measures for the protection and promotion of the health of school-age children have resulted and there is a ground swell of interest which promises to project this progress consistently into the future. The Association never presented a plan of its own, but was ready at all times to act as an exchange of information and a cooperating and counseling agency.

This fall, there will be held the sixth Biennial Conference on Physicians and Schools, which has become a traditional Highland Park Conference whose veteran participants belong to the "School Bell Club," having attended all conferences to date.

The Association also has had many other activities looking to the better health and fitness of American youth, including a broad program of health education, campaigns against quackery and charlatanism, the extension of rural health facilities, and medical service plans. Health and fitness aims are nothing new to the medical profession.

Physicians see in the renewed interest stimulated by the President of the United States an opportunity and a challenge. Fitness, according to the medical concept, must be based on essential fundamentals of which the first is good physical and emotional health.

To achieve this end, we must have good nutrition, periodic evaluation of health needs, follow-through efforts to meet these needs, intelligent attention to healthful living at home and in the school; adequate recreation and activity, the development of personal sports, and emotional adjustment to circumstances as they arise. A broad concept of fitness must not exclude the handicapped, who within their limitations must be helped to attain such measures of fitness as are available for them. Indeed, many a handicapped person stands as a luminous example to his fellows, through his achievements in the face of obstacles and discouragement.

Interest by the President of the United States has naturally stimulated great publicity. Everyone, with the remotest interest in fitness, has presented his viewpoint. This is the essence of a democracy and no one should wish that any of these voices be silenced. By the same token, however, the medical profession now faces a challenge to let its own voice be heard. The position of medicine with regard to the fitness of American youth should be clear and unequivocal.

Medicine stands for a broad concept of fitness, as indicated above. Medicine does not discourage activity, sports, competition, or even a reasonable risk of injury. Medicine recognizes that a fractured ankle may leave less of a scar than a personality frustrated by reason of parental timidity over participation in contact sports. Medicine does recognize, however, that there are contact sports which have for their main purpose, rather than competition and victory, injury to the opponent. Medicine recognizes also that there are contact sports and degrees of competition which are too severe for the immature. In standing out against the abuse of highly desirable exercise and highly necessary competition, medicine in no way objects to activity, competition, and risk, in its proper place. All life is a risk and without courage life is not worth living.

Medicine does deplore the fallacious use of the examination statistics from draft registration as a measure of health. These statistics do not take into account the voluntary enlistments nor do they consider deferments or exemptions from military service for reasons other than health; especially industrial, educational, and religious deferments. The statistics are based on fluctuating values and on essential military standards. They are a measure of military availability only and should not be quoted as indexes of the health of the nation's youth.

Medicine agrees with the Vice-President of the United States that American youth is not soft and decadent; it may be out of training but it has the basic health essentials for the quick acquisition of the necessary military skills. Height and weight figures show that our young people are stronger and heavier than any previous generation; the chances of a baby living to attend school are 96 in 100; the chances of a school child finishing his elementary and secondary education are 99 out of 100 on the basis of life and health, exclusive of economic and other considerations. Average length of life and life expectancy at birth are both at a high level. The conquest of diseases and disabilities affecting youth has brought into focus as our principal problem the conditions in the geriatric ages.

The medical profession may be counted upon as always to give its wholehearted cooperation to any worthy project embraced in the President's broad program for the fitness of American youth. By the same token, the medical profession will speak out without fear against any unsound proposals or against any movements which are wasteful, duplicating, and competitive to sound existing programs. The President's program conceived on a national level will be implemented largely on the local level. Physicians will be kept informed of developments through the columns of The Journal and other channels of communication. State and local medical societies have an opportunity and an obligation to make known to their communities their interest and willingness to participate in community action toward the greater fitness of American youth.

ORGANIZATION SECTION

DOCTORS, BROADCASTERS TO SPONSOR CONFERENCE

Representatives of medical societies, radio and television stations, voluntary health organizations, medical schools, and other allied groups are invited to attend a national conference on "How to Use Local Television and Radio in the Health Field" Nov. 7-8 at Chicago's Sheraton-Blackstone Hotel. The two-day conference is being sponsored jointly by the American Medical Association and the National Association of Radio and Television Broadcasters.

In announcing the meeting, Dr. David B. Allman, president of the A. M. A., and Harold E. Fellows, president of the N. A. R. T. B., said: "Public interest programs involving medical subjects are appearing more and more frequently on radio and television. Both broadcasters and physicians want to be sure that such programs are interesting, informative and factually correct. We hope that this meeting will enable those concerned to do a better job."

The fall conference will consist of a morning of general sessions on such topics as "Mutual Obligations in Public Interest Programming" and "How Accuracy and Good Taste Can Be Assured" and two half-days of section meetings. The sections, set up according to size of community, will discuss specific problems and offer broadcasters and medical representatives an opportunity to exchange ideas.

Only a limited number can be accommodated at the conference, so advance registration is advisable. Register by writing the American Medical Association, Department of Public Relations, 535 North Dearborn, Chicago 10, Illinois. No fee for the conference will be charged, but luncheon tickets will be sold.

HONOR FOUR DOCTORS AS ARTISTS

Four physicians, ranking among America's leading amateur artists, have been honored by the selection of their works for the first major national exhibition of professional-quality paintings by business and professional men.

Included in 38 selections by directors of seven major art museums are paintings by Drs. Joseph A. Falzone Jr. and Gustav Highstein, both of Baltimore; Frank Hinman Jr. of San Francisco, and W. Carl Lindstrom of Tulsa, Okla. Their works were previewed in Milwaukee and then placed on exhibit last June 15 in the Merchandise Mart in Chicago before being circulated by the American Federation of Arts on a two-year tour of art museums, leading universities, and civic centers.

Dr. Falzone is a research physician who has been painting for 12 years without benefit of formal art training. He has had award-winning paintings exhibited by the Society of Independent Artists and by the City Art Museum in St. Louis, the Pennsylvania Academy of the Fine Arts, and the Baltimore Museum of Art. Dr. Highstein, a pediatrician, has won two awards in annual exhibitions of the American Physicians Art Association and has been honored also in exhibits for Friends of the Museum, the Sweat Memorial Museum, the Baltimore Museum of Art, and the Corcoran Gallery of Art. Dr. Hinman started painting during World War II while he was a surgeon aboard an aircraft carrier. One of his prize-winning pictures was reproduced in color in *Life* in 1948. He is associate clinical professor of urology at the California School of Medicine. Dr. Lindstrom is an obstetrician and gynecologist who began taking color photographs, and then turned to painting, while serving as a surgeon in Italy during the last World War. For the past year he has been host to classes of professional men who paint as a hobby.

The current art show, entitled "From the Executive's Easel," is sponsored by Manpower, Inc., a nationwide temporary help service. The exhibition is described as "proof that business and professional people are producing exceptional work while utilizing painting as an escape from the strain of business activities."

NEW A. M. A. COMMITTEE ON AVIATION

The Council on Industrial Health of the American Medical Association is forming a permanent Committee to look into aviation medical problems. A decision to create such a body from an *ad hoc* special committee was implemented late in July by the Board of Trustees. It is hoped that members of the original group, headed by Dr. Jan Tillisch of the Mayo Clinic, will serve on the permanent committee. Investigations of the *ad hoc* committee had brought out: 1. There is an acute shortage of qualified air crew medical examiners. Two-thirds of the 180,000 examinations performed each year are done by family doctors. 2. Pilots disqualified for serious medical conditions—including coronary disorders, epilepsy, diabetes, psychoneurosis, and psychosis—have continued to fly. (One medical witness alleged that less than 1% of pilot medical certification is turned down for physical standards which would disqualify 25% of the general population.) 3. Although the five-member Civil Aeronautics Board proposes rules concerned with medical examinations, its organization has no doctor or medical staff.

Formation of the new A. M. A. permanent Committee on Civil Aviation Medical Problems was expected to be accomplished well before the next meeting of the parent Council on Industrial Health, to be held on Oct. 17, according to Council Secretary, B. Dixon Holland.

RURAL HEALTH MEETING IN OCTOBER

How to develop more effective rural health programs will be the chief topic of concern at the A. M. A.'s second study conference to be held on Oct. 4 and 5 for members of state rural health committees. Sponsored by the A. M. A. Council on Rural Health, the conference will again be held at Purdue University.

The opening session will be devoted to a discussion of organizational techniques of statewide rural health committees. Another session will feature representatives of leading farm organizations outlining their health programs. Following this latter presentation will be a discussion of ways that the medical profession and agricultural groups can best work together in developing better health programs. Reservations for this conference should be sent directly to the Student Union, Purdue University, Lafayette, Ind.

SIXTH NATIONAL SCHOOL HEALTH CONFERENCE

The theme of the sixth National Conference on Physicians and Schools to be held Oct. 30–Nov. 2 at the Moraine Hotel, Highland Park, Ill., will be entitled "A Decade of Progress in Fitness." Sponsored by the A. M. A. Bureau of Health Education, the program will emphasize a continuing interest in the health and fitness of children and youth.

More than 60 consultants and resource persons have been selected from the fields of medicine, education, and public health to lead the discussion groups on the physician's role in youth fitness; community coordination; mental and emotional aspects of fitness; dramatizing basic fitness procedures; medical guidance in girls' recreation programs; special health problems in athletics; fitness of school personnel; optimum fitness for youth with special health problems; home and family relations; and food factors in fitness.

As in previous conferences, state medical societies, state health and education departments, and national agencies concerned with school health and health education have been invited to send representatives. State societies should select their delegates and notify the Bureau as soon as possible. In addition, medical associations should encourage state health and education departments to send representatives so that a nucleus of well-informed persons from several professions can lend interprofessional leadership to school health activities within each state.

HOTEL RESERVATIONS FOR THE ANNUAL MEETING

SAN FRANCISCO, JUNE 23-27, 1958

For the convenience and protection of members of the American Medical Association, exhibitors, and guests, there will appear in the advertising section of THE JOURNAL as early as January, 1958, a list of San Francisco hotels, convention rates, and a room reservation form. The Housing Bureau has been instructed to give this form preference in the allocation of rooms that are reserved under contract with the San Francisco hotels, the Convention Bureau, and the American Medical Association.

Physicians attending the several pre-A. M. A. conventions (which are held during the prior week) are also expected to use this form to secure accommodations for the period of these respective pre-A. M. A. meetings.

CONFERENCE ON NUTRITION IN PREGNANCY

The A. M. A. Council on Foods and Nutrition has selected "Nutrition in Pregnancy" as the title of its 1957 symposium to be held Oct. 11 at the University of Missouri Medical Center, Columbia, Mo. Joint sponsors with the A. M. A. are the University of Missouri Medical School and Adult Education and Extension Service and the Boone County Medical Society. The symposium will provide an excellent opportunity for physicians, nutritionists, dietitians, nurses, and others to acquaint themselves with current findings in nutrition and the practical application of these findings to the management of obstetric patients.

Topics to be discussed include the influence of maternal nutritional level on the fetus and infant; metabolic and biochemical changes in normal pregnancy; importance of nutritional state of mother prior to conception; nutrition experiments as an instrument of teratologic research; the effect of the reproductive cycle on nutritional status and requirements; and dietary habits during pregnancy. Epidemiologic studies will be reviewed in a panel discussion.

SPECIAL COMMITTEE ON INFLUENZA

Report of the Council

The following report, prepared by the Council on Drugs at the request of the Special Committee on Influenza, is presented as a matter of scientific information for the medical profession.

Harold C. Lueth, *Chairman.*

ANTIBIOTICS AND INFLUENZA

The explosive outbreak of influenza during the past spring in the Orient, together with its erratic spread to Europe and the Western hemisphere, has recalled to the minds of many physicians the pandemic of influenza of 1918-1919. In the spring of 1918, a mild but widespread and explosive epidemic of influenza broke out in Europe. In many military units on the Western Front, the incidence of influenza reached a rate of 50% within a period of 10 days to 2 weeks. Certain civilian communities in Europe had comparable incidences of this mild type of influenza. The disease, in the spring of 1918, had a very low mortality rate and practically disappeared from the fighting forces and civilian communities by July 1, 1918. However, in September and in succeeding months influenza returned, and all communities in the world except those that were completely isolated (Tristan da Cunha, for example) were stricken by the infection. In its waves in 1918 and 1919, the disease was characterized by (1) a high morbidity rate, (2) an ability to injure the lungs, thus facilitating the invasion of micro-organisms which produced pneumonia, and (3) a high case fatality rate among those patients who developed pneumonia. It has been estimated that 20 to 30 million people died during this pandemic.

The influenza viral infection in the fall and winter of 1918-1919, while prostrating in effect, did not kill in itself except rarely. Pneumonia and its complications produced by beta-hemolytic streptococci, micrococci (staphylococci), pneumococci, influenza bacilli, and rarely by certain other organisms were responsible for the deaths.

There has been a close and disturbing parallel between the outbreaks of influenza which have been observed in Asia during the past spring and which spread to the Western world and the vernal appearance of what was called Spanish influenza in 1918. The question which is agitating the minds of many physicians at the moment is whether they will witness this fall a recrudescence of influenza throughout the world comparable in incidence and severity (as far as secondary infection is concerned) with that which occurred in the winter of 1918-1919.

Should this occur, what policies should guide the physician relative to the prophylaxis and treatment of secondary bacterial infection in patients suffering from influenza? After a careful consideration of this whole problem, the Council on Drugs makes the following suggestions:

1. Since sulfonamides and antibiotics have no therapeutic effect on the viruses of influenza, their use in the primary treatment of influenza would be contrary to good medical practice.

2. Antibacterial compounds such as sulfonamides or antibiotics should not be generally used in the prophylaxis of bacterial infection in patients ill with influenza. The prime reason for this recommendation is to prevent the development of disease-producing strains of micro-organisms which would be resistant to sulfonamide or antibiotic therapy. The secondary reason is to obviate the development of reactions of sensitivity or of direct toxicity to antibiotics or sulfonamides. The possible exceptions to this injunction are (*a*) pregnant women, debilitated infants, and older individuals, (*b*) patients being treated for other bacterial infections with sulfonamides or antibiotics who develop influenza, and (*c*) patients suffering from chronic, nonallergic respiratory tract disease.

3. All patients ill with influenza in whom it has been demonstrated that secondary bacterial infections have developed should be treated with a sulfonamide or antibiotic of choice. In general, the following recommendations can be made as to the choice of sulfonamides and antibiotics: (*a*) pneumococcic pneumonia: penicillin, broad-spectrum antibiotic, sulfonamide; (*b*) beta-hemolytic streptococcic pneumonia: penicillin, broad-spectrum antibiotic, sulfonamide; (*c*) influenzal bacillary pneumonia: broad-spectrum antibiotic; (*d*) micrococcic pneumonia: this will be a real problem because of the resistance of strains of these organisms to sulfonamides and antibiotics. Careful testing of the sensitivity to the various antibiotics of micrococci isolated from patients ill with pneumonia should be done and the choice of the antibiotic made upon data garnered from these tests. If the condition of the patient is so grave as to necessitate immediate therapy, massive intravenous doses of penicillin plus 1 Gm. of streptomycin per day may be administered while the results of antibiotic sensitivity tests are being awaited.

Finally, a word of caution should be raised relative to the hospitalization of patients ill with influenza. It is the carefully considered opinion of the Council on Drugs that patients ill with uncomplicated influenza should be treated at home. It is a well-demonstrated fact that in many hospitals a high percentage of personnel such as doctors, nurses, and attendants may be carriers of micrococci which are resistant to antibiotic or sulfonamide therapy. A patient ill with primary influenza who is introduced into such an environment would certainly be in jeopardy of contracting a micrococcic pneumonia which could not be cured by antibiotic or sulfonamide therapy.

CURRENT STATUS OF ASIAN INFLUENZA

The following report has been compiled from late data furnished to the American Medical Association's Special Committee on Influenza by the Communicable Disease Center of the Public Health Service, U. S. Department of Health, Education, and Welfare. Progress reports on Asian influenza will be transmitted to the profession regularly as long as there is a possibility of an epidemic.

Harold C. Lueth, *Chairman.*

There appears to be an increase of influenza-like illness in further civilian groups. A school-centered outbreak has occurred in Mississippi and a housing development has been affected in California. A Florida community also appears to have experienced an increased incidence of influenza-like illness in the past week.

Outbreaks and cases of influenza due to Asian strains were confirmed during the period June 1-Aug. 22 in the following locations: California (San Francisco, San Diego, Monterey, Davis, San Mateo, Los Angeles), Virginia (Norfolk), Rhode Island (Newport), Hawaii, Ohio (Cleveland), Iowa (Grinnell), Utah (Salt Lake City), Kansas, (Topeka), Maryland, Kentucky (Louisville, Morris Fork), Pennsylvania (Valley Forge, Lancaster, Old Forge), Texas (Corpus Christi, Bexar County), Washington (Seattle), Nebraska (Omaha), Florida (Jacksonville, Miami, St. Petersburg), Michigan (Calhoun County, Bay County, Coldwater), Louisiana (Grant Parish, Tangipahoa Parish, New Orleans), New Jersey (Burlington County), New York (Cayuga County, New York City), Oregon.

Reactions to Influenza Vaccine Containing Asian Strain Virus

Of 239 volunteers vaccinated with monovalent Asian strain influenza vaccine, 158 were examined and questioned, for the purposes of this report, concerning postvaccination reactions. Injections were given intramuscularly over the deltoid area, and subjects were approached two or three days later. Vaccination groups included one each at 50, 100, and 200 CCA (chick cell agglutination) units and an equal number of saline and aluminum phosphate adjuvant subjects at each dosage level.

The volunteers were examined or questioned for evidence of local erythema and pain or swelling and any other postvaccination symptoms. *Any* affirmative reply was considered a positive reaction regardless of whether mild or severe. Care was taken to differentiate immediate injection pain and venipuncture discomfort from postvaccination signs and symptoms.

Reaction to Monovalent Asian Strain Influenza Vaccine

Reaction	% of 48 People Questioned After Dose of 50 CCA Units	% of 53 People Questioned After Dose of 100 CCA Units	% of 57 People Questioned After Dose of 200 CCA Units
Fever	6	8	14
Generalized pain in extremity*	21	23	54
Local swelling*	2	11	18
Local pain at injection site*	17	19	42

* Includes mild through severe reactions.

With the one exception noted below no severe reactions occurred. Symptoms were primarily those noted in the table and, with rare exceptions, lasted no longer than 12 to 24 hours. An increase in reactions was seen as the dosage of vaccine increased. Among those who had febrile reactions, only three were concerned enough to actually record their temperatures. Other symptoms mentioned in a few instances included malaise, myalgia, and headache. These were unrelated to dosage of vaccine. Differences in reaction to saline and adjuvant vaccines were not significant.

A single subject experienced sufficient fever, malaise, and myalgia to lose one-half day of working time. Otherwise, the symptoms noted were so mild that normal clerical activities were not interfered with or the subjects made unduly uncomfortable.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

In order to furnish the medical profession with a brief historical résumé of the factors underlying the development of Residency Review and Conference Committees as well as the significance of their role in the evaluation of graduate medical education, the Council has authorized publication of the following statement. Edward L. Turner, M.D., *Secretary.*

BACKGROUND AND DEVELOPMENT OF RESIDENCY REVIEW AND CONFERENCE COMMITTEES

During the first two decades of the current century the Council on Medical Education and Hospitals of the American Medical Association was primarily concerned with the improvement of undergraduate medical education. Although it was apparent that this area would be a constant field of interest and concern, the Council recognized during the second and subsequent decades the need for increased emphasis on and improvement of advanced education and training beyond medical school. There was growing conviction in medicine that the learning process must continue throughout life and, as Ray Lyman Wilbur stated, "The doctor who stops learning goes backward."

Those concerned with undergraduate education during the earlier decades of the century were so deeply involved in its improvement that the medical schools themselves for many years evidenced little or no interest in graduate and continuing education. However, the terms "resident" and "resident physician" have been utilized in the United States for well over a hundred years, although at first they were more or less interchangeable with the term "intern." In 1889 Johns Hopkins Hospital instituted the use of the term "resident" to identify the young physician who, having completed an "internship," continued his training in a hospital so as to perfect himself in a special field of medicine. Thus at that time the educational aspect of graduate experience differentiated the resident from that of the salaried house officer whose function was to aid the medical staff in the care of patients, with little or no emphasis on graduate education.

During the 10 years following the Flexner Report, which appeared in 1910, along with the significant advances that took place in undergraduate medical education, increased attention was focused on education beyond medical school. The first major step in this direction was taken by the Council on Medical Education in the initial listing of hospitals approved for internship in 1914 and the survey of graduate medical schools and graduate education which it conducted in 1913-1915. As Johnson has stated, this survey and a subsequent one in 1919 indicated that the existing facilities for advanced training at that time were entirely inadequate. The demand by physicians for advanced training of high quality was not being met, proprietary schools and postgraduate schools of doubtful character were too plentiful, and there was little index of medical school interest in these fields.

Development of Specialty Boards

In 1917, to aid in insuring against the dangers of shortcuts to specialization, the ophthalmologists created the first of the specialty boards. This represented the first effort on the part of a specialty group to determine and uphold the basic requirements in education and experience needed to qualify as an acceptable candidate for examination and certification.

Wilbur reported that in 1919 there existed two large groups of physicians seeking study beyond medical school: those desiring continuing study for short periods and others who desired longer and more exacting preparation to fit themselves for special practice. Both groups involved a total of 10,000 physicians at that time. Approximately 6,000 were seeking short-term study and about 4,000 were engaged in prolonged training directed toward specialization. The Council became especially concerned with the latter group seeking to prepare for specialization, as it was felt that both the public and the profession should be protected against shortcuts to specialization, particularly in surgery, where abbreviated preparation was already being condemned.

Consequently, in 1920 the Council organized 15 committees of nine members each to study and "to recommend what preparation was deemed essential to secure expertness in each of the specialties." It is of interest to note that at that time 11 clinical and 4 basic science areas were included in the committee assignments. The clinical fields included: (1) internal medicine, (2) pediatrics, (3) neuropsychiatry, (4) dermatology and syphilology, (5) surgery, (6) ophthalmology, (7) otolaryngology, (8) orthopedic surgery, (9) urology, (10) obstetrics and gynecology, and (11) public health and hygiene. The basic medical science committees included: (1) anatomy, (2) physiology, (3) pharmacology and therapeutics, and (4) pathology-bacteriology. The 11 clinical fields and one of the original basic science areas subsequently have been included in the 19 American Specialty Boards which exist today.

The organization of these committees by the Council in 1920, therefore, essentially created the pattern underlying the establishment of the specialty boards in medicine and represented the forerunners of the American Boards. Initially the committees submitted widely divergent recommendations in regard to the minimum time requirements for specialization in the different areas. This varied from six months to three years, in contrast to the usual present-day requirements of three or more years beyond the internship. By 1923, the House of Delegates of the American Medical Association, on recommendation of the Council, adopted standards of specialty training referable to eligibility, program supervision, qualifications of instructional staff, and such factors as hospital, dispensary, laboratory, library, and museum facilities. The original statement in regard to the nature of instruction is of interest, for it included: "a) Review courses in anatomy, pathology and the other basic preclinical sciences which apply to the respective specialties; b) clinics in which students can have the opportunity personally to examine patients in hospital wards and outpatient departments and in which various therapeutic and operative procedures can be demonstrated; c) courses of operative and laboratory technic, and d)—to be assigned when the student's previous training will warrant—assistantship in which, *under the supervision of a physician who is recognized as an expert in the particular specialty, he can gradually assume responsibility in the diagnosis and therapeutic or operative treatment of the sick.* Opportunity should be provided also for research work in the chosen specialty bearing on both the fundamental sciences and clinical fields."

One of the most important features of this original statement is still the core of all sound programs of graduate education and training today, namely, the gradual upgrading of responsibility under competent supervision to the point where the physician on completion of his residency should be able to assume full professional responsibility in the diagnosis and in the determination of proper therapeutic procedures.

By 1928 these basic standards, after elaboration and redefinition, were incorporated into the documents of the Council and approved by the House of Delegates under the title of Essentials of Approved Residencies and Fellowships. The year previously (1927) the Council presented its first listing of hospitals approved by it for residency training in the various specialties. In that year. 278 hospitals provided 1,776 residencies. The significance and rapidity of development of specialty training is supported by the rapid growth of residency training since that time as summarized in table 1.

In 1933 the House of Delegates of the American Medical Association adopted a resolution authorizing the Council on Medical Education and Hospitals "to express its approval of such special examining boards as conform to the standards of administration formulated by the Council" and providing for the employment of the "Machinery of the American Medical Association, including the publication of its Directory, in furthering the works of such examining boards as may be accredited by the Council." The Council, therefore, was delegated the responsibility of approving on behalf of the American Medical Association those boards whose organization and administration meet with its approval. This responsibility was not limited to initial approval of an examining board but also to its continued approval by the Council as implied in the listing of such boards in the Directory of Approved Internships and Residencies and other official American Medical Association publications.

During 1933-1934 the Advisory Board for Medical Specialties was organized. From the beginning it has included representatives from each of the approved boards, to "act in an advisory capacity to such organizations as may seek its advice concerning the coordination of the education and certification of medical specialists." The Council on Medical Education and Hospitals has maintained close liaison with the Advisory Board for Medical Specialties through joint meetings and frequent conferences. During the past few years the Council and the Advisory Board have co-sponsored one of the major sessions at the Annual Congress on Medical Education and Licensure.

TABLE 1.—*Data Showing Rapid Growth of Residency Training Programs*

Year	No. of Hospitals	No. of Residency Positions
1927	278	1,776
1930	338	2,028
1935	392	2,564
1940	587	5,120
1945	736	7,666
1950	1,079	18,669
1955	1,201	25,841
1956	1,211	27,835

The "Essentials for Approved Examining Boards in Specialties" originally adopted by the House of Delegates in 1934, and as subsequently revised in keeping with developments indicates that the purposes and functions of a specialty board are: "a) To assist in improving the quality of graduate education in that field, b) to establish minimal educational and training standards in the specialty, in conformity with the general provisions of the 'Essentials,' c) to determine whether candidates have received adequate preparation as defined by the Board, d) to provide comprehensive examinations to determine the ability and fitness of such candidates, and e) to certify to the competence of those physicians who have satisfied the requirements of the board, as a protection to the public and profession."

The "Essentials" then outlined the general organization of a specialty board and the desirability of incorporation of specialty segments or subspecialties within the framework of major boards rather than developing independent boards. The "Essentials" also outlined the general qualifications of candidates for admission to specialty board examination and the mechanisms of establishing an acceptable specialty board, rendering approval in the specialties and basis for withdrawal of approval of a specialty board.

By 1949 there were 19 Approved Examining Boards in Medical Specialties as indicated in table 2. The American Boards of Internal Medicine, Pediatrics, and Surgery, in addition, certify in certain subspecialties and the American Boards of Obstetrics and Gynecology, Otolaryngology, Pathology, Preventive Medicine, Psychiatry and Neurology, and Radiology offer special certification in various areas of their respective fields. Table 2 indicates the names of the present approved examining boards in the medical specialties (1956), the date of their activation, total certificates awarded to June 30, 1956, and the various areas of special certification which have developed.

TABLE 2.—*Approved Examining Boards in Medical Specialties—1956*

Name of Board	Yr. of Activation	Total Certificates Awarded to June 30, 1956
American Board of Anesthesiology	1937	1,503
American Board of Dermatology	1932	1,713
American Board of Internal Medicine	1936	10,470
American Board of Neurological Surgery	1940	666

* Independent Board established in 1949.

Since the American Boards, as well as the Council were concerned with the development of high-grade educational services, it was recommended in 1939 that a cooperative plan be developed for the joint study and appraisal of residencies and fellowships in the various specialties. This plan provided (*a*) that, after conference with the respective specialty board, a suitable application blank be prepared in triplicate so that one copy would be available to the Council, one to the specialty board, and one for the hospital files, (*b*) that an inspection be carried out by the Council's staff to confirm and amplify the information submitted by application, (*c*) that an inspection report be prepared emphasizing objective data that could subsequently be utilized in the evaluation of the educational program, (*d*) that copies of the application and inspection report be forwarded to the secretary of the board for further evaluation, and (*e*) that subsequently the application be submitted to the Council with the recommendation of the Board.

Most of the specialty boards soon entered into cooperation with the Council. In a short time all existing boards except ophthalmology were taking an active part in the study and evaluation of residency training programs. The American Board of Ophthalmology cooperated in supplying information to the Council but did not consider itself an evaluating or approving agency.

It is important, in connection with background information leading to the establishment of residency review and conference committees on graduate education, that the respective roles of the College of Surgeons and the College of Physicians, as well as the role of the Council on Medical Education and Hospitals in improving and evaluating residency education and training be summarized.

Development of Conference Committee on Graduate Training in Surgery

Almost from its foundation in 1913 the American College of Surgeons evidenced interest and concern in the evaluation and approval of hospitals and in 1918 began its hospital standardization program. It employed a hospital inspection staff and pursued an application of more strict compliance with requirements pertaining to staff organization, hospital records, and staff meetings than was required by the Council for hospital registration at that time. The American College of Surgeons did not participate in the evaluations and approval of intern training programs. In 1928 the Board of Regents of the College of Surgeons indicated its interest and concern in graduate training in surgery from the standpoint of its relation to Requirements for Fellowship in the College as well as in relation to the provision of facilities to enable surgeons to achieve competency in surgery and the surgical specialties

In 1937 the College of Surgeons instituted a survey of selected hospitals, and in January, 1939, it published a list of hospitals in the United States and Canada approved for graduate training in surgery. At the same time, a minimum standard was prepared which became known as "Fundamental Requirements for Graduate Training in Surgery." These "Fundamental Requirements" were oriented toward acceptable programs providing three or more years of organized, institutional graduate training—except in ophthalmology and otolaryngology in which two years were accepted if separate training programs were maintained. They also outlined the staff organization, educational committee, supervisory responsibilities, provision for basic medical science instruction, clinical facilities for both inpatient and outpatient activities, library, staff meetings, and conferences, etc.

The main differences between the Council's "Essentials of Approved Residencies and Fellowships" and the College of Surgeons' "Fundamental Requirements for Graduate Training in Surgery" at that time resided in the facts that (1) the American College of Surgeons approved only hospitals offering the full three-year program of residency training (except for ophthalmology and otolaryngology) and (2) in program evaluation the College placed greater emphasis on provisions for formal training in the basic medical sciences. During the period from 1937, the Council and the College conducted their respective programs and it was not until February, 1948, that a Joint Committee representing the American College of Surgeons and the American Medical Association met to discuss problems of mutual interest in this field of hospital surveys and the evaluation of graduate medical education and training. Representatives of some of the American Boards, the Advisory Board of Medical Specialties, and the Council on Medical Education and Hospitals of the American Medical Association were also present.

It was the sense of this general meeting that desirable economies of effort, time, and money could be accomplished if the American College of Surgeons and the Council on Medical Education and Hospitals of the American Medical Association would organize a single acceptable survey service which both organizations could support and be guided by and that, in addition, the joint procedure should be concerned chiefly with educational and organization programs of hospitals for residency training which should be supplemented by professional evaluation by the boards concerned. A subcommittee of the Joint Committee on Hospital Problems was appointed with representatives from the American College of Surgeons, the American Medical Association, the Specialty Boards (Orthopedic Surgery and Surgery), and the Advisory Board for Medical Specialties, which met in April, 1948. This subcommittee, in effect, became the forerunner of the Conference Committee on Graduate Training in Surgery.

Minutes of the Joint Committee on Hospital Problems held in July, 1949, include the following resolutions:

> Resolved, That mutually acceptable standards of residency training in surgery and the surgical specialties be drafted by a committee appointed by the Chairman of the Subcommittee on Hospital Problems and representing the Council on Medical Education and Hospitals and the American College of Surgeons; *the standards so formulated to be referred to the appropriate bodies of the parent organizations for ratification.*
>
> Be it further resolved, That a single uniform list of institutions approved for residency or graduate training in surgery and the surgical specialties be published by the Council on Medical Education and Hospitals and the American College of Surgeons. The Committee authorized in the previous resolution is also charged with formulating recommendations as to the specific procedures to be followed in preparing and publishing such a list.
>
> Be it further Resolved, That the Chairman of the Subcommittee on Hospital Problems be authorized to appoint a committee to study ways and means of effecting a single survey service and that this committee report back to the Subcommittee on Hospital Problems at the earliest possible date.

After a series of committee meetings, conferences, and discussions, a meeting was held in May, 1950, attended by representatives of the American Medical Association, the American College of Surgeons, and the American Board of Surgery. The purpose of this meeting was to initiate the actions that had been given approval by the American Board of Surgery, the American College of Surgeons, and provisional approval of the Board of Trustees of the American Medical Association, as it was believed essential to get the coordinated residency approval program under way.

The minutes of this meeting clearly state that *it is the purpose of this conference to encourage the adoption by the sponsoring agencies of uniform standards for residency training in surgery, to sponsor a single inspection service for hospitals offering such training, and to approve and publish a list of acceptable residency programs.*

During the same meeting it was determined that the committee representing the American Board of Surgery, the American College of Surgeons, and the Council on Medical Education and Hospitals of the American Medical Association be called the Conference Committee on Graduate Training in Surgery.

The development of tripartite committees for the surgical specialties has been supported by both the Council and the College.

After further study and negotiation between the Council on Medical Education and Hospitals, the American College of Surgeons, and the American Board of Surgery, a "Joint Commission on Accreditation of Residencies in (General Surgery, Otolaryngology, etc.)" was recommended in 1953. Because of possible confusion from the use of the appellation "Joint Commission" the name reverted to the "Conference Committee on Graduate Training in Surgery." The Conference Committee on Graduate Training in Surgery is a tripartite committee with equal representation from the Council on Medical Education and Hospitals, the American College of Surgeons, and the American Board of Surgery. As currently agreed, the chairman and vice-chairman are representatives of the American College of Surgeons and the American Board of Surgery, with the provision that both of them should not be from the same body and that the chairmanship should alternate between the organizations at intervals of two years. The secretary of the committee is a representative of the American Medical Association (currently a member of the staff of the Council on Medical Education and Hospitals as ex officio member).

Development of Residency Review Committee in Internal Medicine

In internal medicine the original movement to initiate a cooperative effort in graduate education and training stemmed from a meeting of the Board of Trustees of the American Medical Association and the Board of Regents of the American College of Physicians in April, 1939. Subsequently, plans for the formation of a Conference Committee on Graduate Training in Internal Medicine (now the Residency Review Committee in Internal Medicine) were developed in May, 1939, at a meeting attended by representatives of the Council on Medical Education and Hospitals, the American Board of Internal Medicine, and the American College of Physicians. The first organizational meeting was held in February, 1940. This Conference Committee appraised residencies through joint evaluation of hospital educational programs in internal medicine, meeting two or three times annually and functioning effectively and to mutual advantage until World War II interrupted its activities. During World War II the Council continued the approval of residencies in Internal Medicine in cooperation with the American Board of Internal Medicine.

A movement to reactivate the Conference Committee on Graduate Training in Internal Medicine originated with the American College of Physicians in 1947. At its meeting in June, 1947, and on two subsequent occasions, the Council on Medical Education and Hospitals voted to reactivate the Committee. In June, 1948, at the suggestion of the Board of Regents of the American College of Physicians and on invitation of the Council, a joint meeting was held in Chicago, at which time all three organizations (the Council, the College, and the American Board) agreed to reactivate the Conference Committee. The organizational meeting for Reactivation was held in February, 1949.

It is important to note that the two primary functions of this committee were indicated to be (1) the evaluation of residency programs in internal medicine, including new applications and reevaluation of approved programs, and (2) the establishment of standards for residency training in internal medicine. With regard to the latter, *the Committee's function was indicated to be recommendation to the sponsoring organizations.* Both Council and College agreed to these basic functions and the American Board of Internal Medicine in October, 1949, indicated its concurrence in granting authority to the Conference Committee to act also for it in the matter of residency approval and in the assignment of time credit for each residency.

In 1953 the Conference Committee on Graduate Training in Medicine officially changed its name to Residency Review Committee in Internal Medicine, in keeping with the belief that this name more adequately described its activities. This committee functions as a tripartite organization.

Residency Review Committees in Other Specialties

Obviously as an outcome of the development of the Conference Committee on Graduate Training in Surgery and the Residency Review Committee in Internal Medicine, there was increasing interest in the establishment of Residency Review Committees in each of the specialties with which the Council was collaborating. In the fall of 1952, therefore, a proposal was made to the Council that such committees or boards be developed in cooperation with each of the specialty boards, so that they could act for both groups in the approval of hospitals for residency training. It was proposed that each organization (the Council and the specific specialty board) would appoint representatives to the Residency Review Committee who would not necessarily be members of either organization but who would be specialists in the field concerned who were interested and experienced in residency training. The proposal suggested that administrative procedures for such committees be established in the office of the Council, which would have the secretarial representative, and that the chairman be selected from the Board representation in each instance. The proposal was endorsed by the Council and authority given to communicate with the Advisory Board for Medical Specialties and also with the respective boards (other than Surgery and Internal Medicine) as to their interest in such a development.

By May, 1953, five specialty boards had expressed their interest in establishing Residency Review Committees (orthopedic surgery, otolaryngology, pediatrics, proctology, and radiology), and subsequently committees have been established in all areas except obstetrics and gynecology, pathology and thoracic surgery. Although most of the Residency Review Committees are bipartite groups with representatives from the Council on Medical Education and Hospitals and the Specialty Board concerned, Internal Medicine, Surgery, and the Surgical Specialties of Otolaryngology and Plastic Surgery function as tripartite committees. Thus the Surgical Specialty Committees referred to also include representatives of the American College of Surgeons. The Council, in cooperation with the American Academy of General Practice, has established a Residency Review Committee in General Practice in an effort to assist in the elevation of graduate education and training in this field outside of the specialty areas.

The Residency Review and Conference Committees thus essentially represent cooperative partnerships through which the Council on Medical Education and Hospitals and the various specialty boards, the American College of Surgeons, and the American College of Physicians are endeavoring to conduct an objective and constructive program of accreditation in graduate medical education.

MEDICINE AND THE LAW

FOREWORD

This is the first in a series of six articles dealing with the necessity for and proper format of certain medicolegal forms. The subjects to be covered are (1) consent to operations and other medical procedures; (2) patient's right to privacy; (3) confidential communications and records; (4) artificial insemination; (5) the physician-patient relationship; and (6) autopsy.

This material has been prepared and will be published in book form by the Law Department of the American Medical Association under the title "Medicolegal Forms with Legal Analysis." The book will include extensive legal citations and a substantial number of additional forms which have not been included in this series of articles.—ED.

Many physicians and hospitals throughout the United States do not follow the practice of requiring the signing of appropriate medicolegal forms in situations where experience has shown that the signing of such forms might have prevented a law suit. In other instances, inadequate medicolegal forms are in daily use. For example, "blanket" consent forms which purport to give the physician unlimited authority and discretion without specifying the particular operation contemplated are used extensively. The use of such forms has given rise to professional liability claims charging the performance of an operation different than the one for which consent was obtained. The courts have construed blanket consent forms to permit only the procedures which were orally agreed upon. In the absence of a consent form that describes within reasonable latitude the nature of the operation or treatment to be performed, a jury can very easily choose to believe the "forgetful" patient whose recollection regarding the treatment he authorized has been dimmed by time or circumstances.

In 1936, an article entitled "Authorization of Physical Examinations, Treatment, Operations, and Autopsies" by Dr. William C. Woodward was published in THE JOURNAL (106:33-40 [Jan. 4]). The present article and the five to follow have a twofold objective: (1) to expand and bring up to date the subject matter covered by Dr. Woodward and (2) to provide miscellaneous medicolegal forms of authorization and consent which physicians and their attorneys may adapt to their own needs.

In preparing these forms for publication, no effort has been made to provide complete uniformity, even with respect to details or format. Generally, the variations which exist do not have any particular legal significance. For example, some of the forms call for the addresses of the signer and the witnesses. Dependent upon local preference and circumstance, it may be preferable to include such addresses in a consent form. On the other hand, where the physician or the hospital already has this information in its records, it would be unessential. It may not be necessary to include the address of an employee witness since this information is usually available elsewhere. When the patient is accompanied by a friend or relative, it is a good policy to have this person sign as a witness and furnish his address, which may be stated either in the form or elsewhere in the patient's record. In these instances it is also desirable that an employee of the physician or hospital sign as a second witness.

If the patient is a minor, and someone else signs the form on his behalf, the relationship, if not apparent, should be stated in the consent form.

In our opinion, revised and up-to-date medicolegal forms should be available to physicians and should be executed by the patient in the physician's office, whenever circumstances permit, even though the hospital may also require the patient to sign similar consent forms. Local legal counsel should be consulted to make such changes in the suggested forms as are necessary to satisfy the laws of the jurisdiction.

Although the text and forms have been prepared to help physicians and hospitals, they are, at best, a poor substitute for competent local legal advice.

CONSENT TO OPERATIONS AND OTHER PROCEDURES

Assault and Battery.—Authority is necessary before a physician may legally examine or treat a patient. A physician who operates upon a patient without having authority to do so commits an assault and battery for which he may be prosecuted criminally or held civilly liable in damages. If the patient upon whom the unauthorized operation was performed is unable to prove that any actual damage was caused by the operation, he will usually be able to recover only nominal damages. However, the fact that the medical profession has not yet discovered the purpose served by the organ removed will not necessarily limit the patient's recovery to nominal damages; pain and suffering is an element of damages in assault and battery and some pain may be presumed to occur in the course of any operation or in the course of recovering therefrom. It is no defense that the unauthorized operation was performed with due skill and care inasmuch as negligence is not an element of this cause of action. Authority for the performance of an operation may arise out of a legal duty or out of the consent of the patient or some one authorized to act in his behalf. In an emergency, authority is implied on the basis that it would probably have been granted.

Authority Provided by Law.—Some states provide, by statute, for the eugenic sterilization of feebleminded persons and habitual criminals. If the law under which the operation has been authorized is a valid, constitutional law, and if the procedure leading up to the order for sterilization has been in conformity with that law, and if the operation is performed in accordance with the law and without negligence, the physician authorized to perform the operation incurs no personal liability in performing it even over the objection of the person upon whom he operates. Similarly, statutory authority protects physicians in charge of state mental institutions, prison physicians, and health officers charged with the enforcement of vaccination and quarantine laws. The conduct of all such officers is subject to review by the courts. If they act beyond the scope of their authority, or if they act in an unlawful manner, they are liable for the payment of damages and may be subject to criminal prosecution.

Authority Provided by Consent.—Usually authority to operate arises from the valid consent of the patient or some one legally authorized to act in his behalf. It should be noted that even a valid consent is no defense in an action for professional negligence. The consent given may be either express or implied and, if express, it may be either written or oral. The consent given must be an informed consent with an understanding of what is to be done and of the risks involved. The procedure involved and its attendant risks should be explained to the patient in understandable nontechnical terms. The consent given may be invalid (*a*) because the act consented to is unlawful, or contrary to public policy, or (*b*) because the consent was given by one who had no legal right to give it, or (*c*) because it was obtained by misrepresentation or fraud.

In order for a consent to an operation to be valid, it must be the rational act of a qualified mind. The consent of the patient to the operation is sufficient, if he (*a*) has attained his majority and (*b*) is, at the time of giving consent, competent to understand the nature and purpose of the operation proposed and the risks involved. The consent of the husband to an operation on his wife is not necessary; the consent of the wife is sufficient authority. Nevertheless, it is advisable to have the spouse join in the consent whenever practicable. It is particularly desirable to do so if the operation involves danger to life, may destroy or limit sex functions, or may result in the death of an unborn child. A person who has attained his majority and is of sound mind is presumptively qualified to give or withhold consent. The presumption may be rebutted, however, by evidence showing that when the consent was given the party was drunk, or under the influence of drugs, or delirious, or comatose or otherwise incapable of exercising rational judgment. Under such circumstances the law will infer consent if the patient's life was at stake and there was no one present to give consent in his behalf. The fact that a patient is being treated free or at the expense of some one else does not do away with the necessity for obtaining his consent.

In agreeing to perform the operation, the physician does not, in the absence of a special contract, guarantee particular results or to cure. The physician warrants only that he possesses the degree of knowledge and skill ordinarily possessed by a member of the profession in good standing in the community and that he will use that knowledge and skill in the performance of the operation. Although admittedly an unsound practice, a physician may expressly agree to accomplish a particular result or effect a cure. If the physician enters into such a contract and fails to bring about the result or to effect a cure, he is liable for breach of contract even though he used the highest possible professional skill.

Invalid Consent.—Consent to a criminal abortion is void because such an operation is unlawful. Consent to an experimental operation that will greatly endanger the life of the patient and which is not intended to relieve or cure his illness or injury, but solely to advance the science and art of medicine, is usually regarded as contrary to public policy and therefore void. In theory, at least, the harm that might be done to society by such experimentation outweighs its possible benefits. Treatment involving an element of experimentation may properly be administered only with the full knowledge and consent of the patient or those legally responsible for him, and then only if the treatment does not vary too radically from the accepted methods of medical practice.

With reference to human experimentation, the House of Delegates of the American Medical Association in 1946 adopted the following statement set forth by the Judicial Council: "In order to conform to the Ethics of the American Medical Association, three requirements must be satisfied in human experimentation (1) the voluntary consent of the person on whom the experiment is to be performed; (2) the danger of each experiment must be previously investigated by animal experimentation, and (3) the experiment must be performed under proper medical protection and management." This statement, of course, assumes the legal prerequisite of therapeutic justification for the treatment undertaken.

An operation for sexual sterilization when such sterilization is not necessary for the cure or prevention of disease or antisocial conduct is generally regarded as contrary to public policy. This view finds strong support in the widespread legislation forbidding the indiscriminate dissemination of information as to how conception may be prevented and the indiscriminate distribution of devices and preparations designed for that purpose. Consent to a sterilizing operation is therefore probably void unless the operation is intended to cure or prevent disease or antisocial conduct or prevent a pregnancy that would endanger life.

Consent Obtained by Fraud.—Purported authority for an operation obtained by misrepresentation or fraud on the part of a physician is not valid authority and affords no protection to the physician. To represent to a patient that an operation is necessary to save life or to preserve health when that is not the case, or that it will give greater relief than there is any reasonable prospect of obtaining, is to perpetrate a fraud on the patient which vitiates his consent. Tactful honesty and frankness on the part of the physician are generally essential.

Minors.—Operations on minors, at least on those who have not attained years of discretion, may be lawfully authorized by the parents or, if there is no parent, by a guardian. If the minor has parents, consent should be obtained from them even though the minor is in temporary charge of some other person. In the instance where the parents are legally separated or divorced, consent on behalf of the child should be obtained from the parent who has legal custody. It is particularly important that consent be obtained when the procedure to which the child is to be subjected is for the benefit of some other person, such as a blood or skin donor.

It is not clear whether valid consent to an operation can be given by a child who has not attained his majority, although he is of sound mind and has attained the age of discretion. The fact that such a child is legally qualified to make a contract for medical services as one of the necessities of life may be construed as authorizing him to consent to an operation, at least when the cost is to be paid by him from his own funds. There may be a conflict, however, between the authority of the parent and the authority of the child, especially if a child is under treatment at the expense of his parents. Such conflicts seldom occur, but when they do they must be settled according to the circumstances of the case and the law of the community. In such cases, it is best that the physician refrain from action until the question of authority is settled, unless immediate medical attention is necessary to preserve the health or life of the child.

A man, and in many states a woman also, attains his or her majority on the day before the 21st anniversary day of his or her birth. In some states the age of majority for women is 18. Presumably, a woman would be regarded, in such states, as having reached her majority on the day before the 18th anniversary day of her birth. In some states the marriage of a minor "emancipates" the minor from parental control and may raise a legal question as to the relative rights of the parents or the emancipated minor where one or the other opposes the operation. In such a case the physician should not act without having first obtained the advice of competent legal counsel.

Consent is sometimes withheld by the parents on the ground that such treatment would be contrary to their religious beliefs or because of ignorance. Where the life or health of the child is in jeopardy, it is suggested that the physician or those interested in the child's welfare report the case to the local prosecuting attorney and to any available child welfare agency, with a view to having them initiate immediate legal action. There are statutes in some states which authorize the juvenile court to order necessary medical and surgical care for a minor whose parent or guardian, when able to do so, refuses to provide it. Pursuant to such statutory authority the courts have issued orders authorizing needed surgical operations and psychiatric examinations, despite the lack of consent on the part of the child's parents. In other states, courts, acting under the general statutes with respect to neglected and dependent children, have deprived the parents of custody and have appointed guardians authorized to provide necessary attention. Some courts have, however, refused to deprive parents of custody when they have refused to provide attention or treatment deemed by some to be necessary.

In determining whether to interfere with the parents' right to the custody and control of their child, the courts weigh the danger of the child's condition against the danger of the operation. Blood transfusions have been ordered, over the objections of the parents, for infants afflicted with an Rh complication. The basis for such court action is that there is only negligible danger in the transfusion while, without it, the child will almost surely die or, if it should live, its mental abilities will be greatly impaired. The court refused to order the amputation of a minor's abnormally large arm which was endangering her general health because the operation involved a serious threat to her life.

Incompetents.—Where the patient is of unsound mind and incompetent to understand the nature, the purpose, and the risks incident to a proposed operation, authority must come, (*a*) if he is a minor, from one or both of his parents, unless a guardian has been appointed for him by the court, in which case it must come from his guardian; or (*b*) if he has attained his majority, from his spouse or legally appointed guardian. An adult not under guardianship who is partially incompetent but sufficiently capable mentally of understanding his need for an operation and the possible consequences may be considered capable of assenting, especially in view of the fact that he is, despite his mental condition, considered in law to be capable of entering into a contract for medical services as a necessity of life. It is, nevertheless, desirable under such circumstances that a relative, or if there is none, some person who has demonstrated a genuine interest in his care and welfare, approve or join in executing the consent.

When an immediate operation is imperative and the patient is unable to consent rationally to the proposed operation, and when delay incident to the obtaining of the consent of some one legally authorized to consent on behalf of the patient involves serious risk to the patient, an operation may be performed on the legal theory of implied consent. The law implies that the patient would, if competent, consent to whatever may be necessary in his own interests. When a surgeon operates under such circumstances he should be prepared to show (*a*) that an immediate operation was necessary; and (*b*) that a lawful express consent could not be obtained from the patient or from any person authorized to act for him, without endangering the health or life of the patient.

Limits of Authority.—Ordinarily, an operation must be performed within the limits of the authority that has been given. The physician may not perform an operation different from that for which consent has been given. The operation must be performed in the manner which has been agreed upon. A consent must be obtained for each individual operation performed. A consent to one operation will not authorize another or later operation, even though the second operation is for the same condition as the first one. Authority may be given, however, for the operating physician to use his own judgment within certain reasonable limitations. It is usually mutually desirable for the physician to request the patient to allow him a reasonable amount of discretion in the performance of an operation. Even in the case of a limited operation, the operating physician must do whatever may be reasonably necessary for the safety of the patient. The ordinary legal implication is that if the patient under anesthesia had known beforehand of the circumstances that make a modification or extension of the operation necessary, or if at the moment he could exercise rational judgment, he would give his consent. Since it is assumed that the patient would consent to that which is for his benefit, the law implies consent in such cases. However, a physician may not, in the course of an authorized operation, perform a different operation or unauthorized supplementary surgery unless a true emergency exists; there must be a condition which if not corrected would be an imminent threat to life or could result in grave and irreparable injury to the health of the patient. It is not enough that the physician thinks that certain procedures will be beneficial to the patient. Also the physician must remember at all times that the patient's consent in no way relieves the physician of his duty to exercise due care in all that he does. Consent to the operation does not authorize any deviation from prevailing standards of care and caution.

Implied and Oral Consent.—An adult patient of sound mind, who knows that he can agree or refuse to submit to an operation, and who knows or has been fully and fairly informed by his physician as to what is to be done, and who then cooperates with the physician, has impliedly consented even though he has not consented in words. Such implied consent is the consent customarily given in routine office practice. Implied consent to operations always involves the possibility of misunderstanding as to the purpose and scope of the undertaking and the difficulty of obtaining proof in the event of a controversy. It is under the legal concept of implied consent that a physician is permitted, in an emergency, to operate on or extend the scope of surgery performed on an unconscious or delirious person who is unable to make his own decision. This situation frequently arises in connection with serious accidents when the patient is unable to act for himself. Of course, if some one is present who has authority to act for the patient or if, without jeopardizing the welfare of the patient, such person can be communicated with before operating, his consent should be obtained.

Oral consent to an operation is ordinarily supplemented by implied consent. For instance, a patient, after orally consenting to an operation, cooperates with the physician in its performance. Like implied consent, oral consent is open to misunderstanding and may be difficult of proof.

Written Consent.—While written consent to an operation is not required by law, it is desirable in order to avoid the misunderstandings that lead to lawsuits and also to facilitate proof when necessary. The prudent physician will demand a written consent or authorization with respect to any operation which involves an element of recognized danger to the patient or which requires hospitalization. No particular form is necessary to give validity to a written consent. The essential requirements are that it state clearly the nature and extent of the operation authorized and that it be signed by a person legally qualified to give consent. The authorization should state who is to be responsible for the administering of the anesthetic and the postoperative care of the patient if these services are to be performed by a physician other than the operating surgeon. The inclusion of the place and date of execution and the signature of a witness are desirable, but only because they tend to facilitate proof. Generally, the more vague and indefinite the terms of the consent, the more specifically it will be construed by the court. Care should be taken to spell out precisely and in the least technical language possible the exact procedure which the physician intends to perform or the particular condition which he seeks to relieve.

Authorizations and consents should be preserved at least for a sufficient period after the operation to cover the entire time within which, under the statute of limitations, a suit may be instituted. The length of the period of limitations varies from state to state.

Although the performance of an unauthorized operation is technically an assault and battery, it appears that an action for such an operation is sometimes governed by the statute of limitations as to malpractice or personal injury rather than by that as to assault and battery.

The physician would be wise to retain the authorizations and consents even after the expiration of the limitation period because the holdings of the courts are not uniform on the question of whether the statute begins to run at the time of the doing of the alleged wrongful act or at the time of its discovery. For minors the limitation period does not commence, generally, until the minor has reached his majority.

If a physician requests a written consent to surgery from the patient at the time the arrangements for surgery are made, the patient will be inclined to inquire as to his condition, the nature of the procedure contemplated, and the attendant risks. Under these conditions there can be no reasonable allegation by the patient later that he was under sedation when he signed the consent form, or that a hospital attendant had stated that the signing of the consent form was a "mere formality." Legally, the physician may rely for his authority upon a consent obtained by the hospital for his benefit, but it is readily apparent that the physician may protect himself best by attending to the details of having the consent form completed, signed, and witnessed in his presence. The use of business methods in dealing with this phase of medicine may reduce the number of liability claims that arise from misunderstandings, from the use of poorly drawn or antiquated medicolegal forms or from failure to use written forms.

Form 1.—*Consent to Operation*

PATIENT .... AGE ....

A. M.
DATE.................................TIME........P. M. PLACE...............

1. I hereby authorize Dr. ....
and whomever he may designate as his assistants, to perform upon ...., the following opera-
(State name of patient or "myself")
tion: ....,
(State nature of procedure(s) to be performed)
and if any unforeseen condition arises in the course of the operation calling in his judgment for procedures in addition to or different from those now contemplated, I further request and authorize him to do whatever he deems advisable.

2. The nature and purpose of the operation, possible alternative methods of treatment, the risks involved, and the possibility of complications have been fully explained to me. I acknowledge that no guarantee or assurance has been made as to the results that may be obtained.

3. I consent to the administration of anesthesia to be applied by or under the direction of Dr. ...., and to the use of such anesthetics as he may deem advisable, with the exception of ....
(State "none", "spinal anesthesia", etc.)

4. I am aware that sterility may result from this operation although such result has not been guaranteed. I know that a sterile person is incapable of parenthood.

5. I consent to the disposal by authorities of the .... Hospital of any tissues or parts which may be removed.

6. I consent to the taking and publication of any photographs in the course of this operation for the purpose of advancing medical education.

7. For the purpose of advancing medical education, I also consent to the admittance of observers to the operating room.

I CERTIFY THAT I HAVE READ AND FULLY UNDERSTAND THE ABOVE CONSENT TO OPERATION, THAT THE EXPLANATIONS THEREIN REFERRED TO WERE MADE, AND THAT ALL BLANKS OR STATEMENTS REQUIRING INSERTION OR COMPLETION WERE FILLED IN AND INAPPLICABLE PARAGRAPHS, IF ANY, WERE STRICKEN BEFORE I SIGNED.

Signature of patient ....
Signature of patient's
husband or wife ....
When patient is a minor or
incompetent to give consent:
Signature of person authorized
to consent for patient ....
Relationship to patient ....
Witness: ....

Note. This is a general form of consent which will apply to various surgical cases by striking out the portions which are inapplicable. Where the anesthesia is to be administered by a nurse anesthetist, the name of the attending surgeon should be inserted in paragraph 3.

Form 2.—*Consent to Disposal of Amputated Part or Organ*

I hereby authorize ....
to preserve for scientific purposes, or for use in grafts upon living persons, or to otherwise dispose of the following named tissues, parts, or organ, ..., of ...., in a proper and suitable
(Name of patient)
manner.

Signed ....
Date ....
Witness ....

Form 3.—*Consent to Treatment*

I, having been fully informed by Dr. ....
of the risks and possible consequences involved in treatment by means of .... for the relief of ...., nevertheless hereby authorize Dr. .... to administer such treatment to me, and agree to hold him free and harmless for any claims, or suits for damages for any injury or complications whatever which may result from this treatment.

Signed ....
Date ....
Witness ....

Note. This is a general form of consent that is intended for use, primarily, in connection with the administration of hazardous drugs and treatment normally provided in the physician's office.

Form 4.—*Consent to Diagnostic Procedure*

PATIENT.. AGE........

A. M.
DATE.......................TIME..........P. M. PLACE.......................

I hereby request and authorize Dr...
and whomever he may designate to assist him to perform upon .... the following
(Name of patient or "myself")
diagnostic procedure: ....
I have been fully informed of the risks and possible consequences involved and that unforeseen results may occur.

Signed ....

The foregoing consent was read, discussed, and signed in my presence, and in my opinion the person so signing did so freely and with full knowledge and understanding.

Witness ....

Form 5.—*Agreement for Blood Transfusion*

To: Dr. ....
(Attending physician)
and.......................................Hospital. Date............19......

1. I hereby request and authorize the administration of a blood transfusion to ....
(Insert "myself" or name of patient)
and such additional transfusions as may be deemed advisable in the judgment of Dr..., the attending physician, or those he may designate to assist him.

2. It is understood and agreed that the attending physician or his assistants will be responsible only for the performance of their own individual professional acts, and that the blood typing and the selection of compatible blood are the responsibilities of those who actually perform the necessary laboratory tests.

3. It has been fully explained that blood transfusions are not always successful in producing a desirable result and that there is a possibility of ill-effects such as the transmission of infectious hepatitis or other diseases or blood impairments.

4. Also, it has been explained that emergencies may arise when it may not be possible to make adequate cross-matching tests, and that immediate need may make it necessary to use existing stocks of blood which may not include the most compatible blood types.

5. It is understood and expressly agreed that the blood supplied in accordance with this agreement is incidental to the rendition of services and that no requirement, guarantee, or warranty of fitness or quality shall apply.

Signature of patient ....

When patient is a minor or incompetent to give consent:

Signature of person authorized to consent for patient ....

Address ....

Relationship to patient ....

Witness: Signature ....

Address ....

City and State ....

COUNCIL ON MEDICAL SERVICE

THE ROLE OF EXERCISE IN THE AGING

Paul D. White, M.D., Boston

This is the third of a series of papers on various aspects of aging. Each paper has been prepared for the Committee on Aging by an authority in the field. When completed, the series will be published in booklet form.

As I sit down to write about the role of exercise in the aging, I am conscious of the pleasant and relaxing effect of a brisk walk in the clear cold air of Santa Fe and the hills around. As a senior member of society, I can vouch for this particular positive effect of exercise; for many aging persons this may be its chief value. However, there are other physiological results of exercise which deserve as much emphasis in the aging as they do in the young, and possibly even more.

Though such effects of exercise are frequently referred to in the presentation of health programs, they are but little discussed in planning for the health and happiness of older persons. To be sure, no hard and fast rules about exercise can be laid down for everyone of a certain age, in the first place, because no two persons have exactly the same physical needs or psychological preferences and, secondly, because chronological age is not the same as physiological age. Also it is true that some individuals live to be old and free from disease despite the fact that the only exercise they get is in breathing, eating, talking, and in tending to their minimal physiological processes of other nature; what percentage of healthy older persons belong in this category has not been determined, but it appears to be considerably in the minority.

Naturally, in extreme old age, when physical strength and mental ability steadily decline, there comes a time when exercise beyond that of the simplest acts of living is no longer possible, but in the early and middle ye of old age exercise can be very beneficial. It is i portant to recognize that there is a difference betwe positive health and the mere absence of disease.

At any age, physical exercise, more or less plann though not as a burdensome or boring program, l certain beneficial effects which can be helpfully viewed in our discussion of the problems of aging. T kind of exercise is not very important except tha should suit the strength, aptitude, and liking of particular person. It may vary in strenuousness fr that involved in simple deep breathing in short peri several times a day to that involved in heavy wo cutting or snow shoveling or fast tennis.

There should be no age set at which a person lo accustomed to vigorous exercise should cease ex cising, although it is usually wise to tone down t energy expenditure and the amount of time per d or week with each passing decade. If a man or wom is in good health and enjoys exercise in the open (or perhaps even if not) the beneficial effects can c tinue to a very advanced age. I have known of Mai guides and lumbermen, gardeners, sailors, labore and sportsmen who have kept up a vigorous progr both enjoyably and beneficially well into the 80's.

There are very few adequate statistics concerni the health and longevity of athletes. Some articles a books have been published on the subject; one of thes entitled "University Oars," was written many yea ago (1873) by Dr. John E. Morgan, who was oarsman himself. Dr. Morgan, of Oxford Universit made a follow-up study of members of the crews wh took part in the annual races between Cambridge an Oxford from 1829 to 1869. His conclusion was th the effect of the rowing was a favorable one, that th type of exercise (some of which was continued years afterward) had no unfavorable effect on heal

---

Consultant in Medicine, Massachusetts General Hospital, and President, International Society of Cardiology.

Members of the Committee on Aging are Drs. H. B. Mulholland, Chairman, Charlottesville, Va.; Edward L. Bortz, Philadelphia; Henry A. Holle, Austin, Texas; Wingate M. Johnson, Winston-Salem, N. C.; Theodore G. Klumpp, New York; Frederick C. Swartz, Lansing, Mich.; and Cecil Wittson, Omaha. Committee Staff: Mr. George W. Cooley, Secretary, and Mr. Herbert B. Norton, Research Assistant.

ut rather the reverse, and that the longevity of the arsmen was slightly greater than that of the average opulation.

A study not yet reported, which my associates and made, was a follow-up of Harvard football players vho earned their letters between the years 1900 and 930. This study showed a longevity close to that exected in the population at large. It had been hoped o compare those who continued vigorous exercise hroughout their lives with those who took no particuar exercise after graduation from college and also hose who had gained very much weight with those vho had gained practically no weight at all. Evidence on these two points was definitely favorable for those vho continued vigorous exercise and who did not gain veight, but the numbers in these extreme groups were ardly adequate for statistical conclusions. One of the difficulties in such a study is that the majority of American males live a standard existence, that is, they eat much the same diet, drink and smoke moderately, get some exercise but not of any considerable degree, and gain a moderate amount of weight through the years (10 to 25 lb. or more in the course of 30 years).

Benefits of Exercise

Exercise has positive effects on the health. In the first place, there is the benefit of establishing or maintaining the general muscular tone throughout the body, including that of the heart itself. Some muscles, of course, become stronger if they are more involved in the exercise, for example, the leg muscles in long walks, golfing, cycling, or tennis, or the arm muscles in wood cutting, gardening, fishing, or housework. One of the muscles that it is important to keep in good tone is the diaphragm; almost any vigorous exercise or even repeated programs of deep breathing will help here.

There are several values that are derived from good muscle tone. One is that which concerns the circulation of the blood itself. Sometimes one forgets that the heart, although the most important factor of course, is not the sole supporter of the circulation. The elasticity of the aorta and other great arteries is of importance in maintaining an even flow of blood. The vasomotor function of the smaller vessels is vital for the selective distribution of the blood to the organs as needed. The peripheral veins with their valves act as local pumps for the return of blood to the heart when they are compressed by the muscles that surround them. The better the tone of the muscles the better is this support to the heart afforded by the veins. For the same reason, peripheral venous stasis of high degree with the development of varicosities, the pooling of blood, and phlebothrombosis is counteracted, to a certain degree at least, by good muscle tone. Finally, good tone of the diaphragm with wide respiratory excursions (aided by the avoidance of obesity) not only greatly helps respiration but also improves the pumping action of the diaphragm in its suction of blood back to the chambers of the right side of the heart.

A second benefit from exercise is that already referred to, namely, its effect on the psyche. Most individuals, old as well as young, are much helped by the relaxation which comes from exercise of the right degree, usually midway in amount and intensity between the extremes of triviality and of exhaustion. For many of us, exercise is a delightful antidote for nervous tension and strains, anxiety, and mental concentration. A pleasant fatigue of the skeletal muscles has time and time again given me mental repose, peaceful sleep, and a sense of equanimity.

A third benefit has been on digestion, partly, in all probability, by reducing nervous tension, which is a common factor in cases of esophageal irritability (cardiospasm) and peptic ulcer, and partly by its favorable effect on the bowel function.

A fourth benefit of exercise at any age, and therefore applicable to the "aging," is its favorable effect in helping to control obesity, a condition widely regarded as inimical to the best of health and longevity. Although it is true that obesity is due to the combined effects of heredity and overnutrition, nevertheless, with the same caloric intake, the increased metabolic requirement resulting from exercise does help to control body weight. It is not the fat deposited under the skin here and there throughout the body or in the omentum that is of most importance but rather a few grams of fat in the wrong places, particularly in the walls of the coronary and other important arteries.

Finally, the deepening of respiration which comes with exercise favors the function of the lungs in gaseous exchange and in the state of the lung tissue itself. Although chronic bronchitis and emphysema are common in old age and limit the amount of exercise possible, they are not a bar in themselves to mild exercise within the reserve of the person affected.

Even in the presence of disease other than in the lungs, suitable exercise can be beneficial. I have seen many patients with heart diseases of various kinds and degree and, except for the most severe cases, slight to moderate exercise can and should be prescribed. Of course, angina pectoris too easily induced or myocardial weakness of considerable degree will demand pro tem absolute rest, but with recovery or in the presence of well-healed myocardial infarction, as in the President's case, a careful program of regular exercise may not only be an important health measure but it may conceivably be helpful, in the absence of important symptoms, in retarding the further progress or increase of coronary atherosclerosis. Further research as to this possibility is in order.

Thus, in conclusion, it may be said that exercise of almost any kind, suitable in degree and duration for the particular individual concerned, can and does play a useful role in the maintenance of both physical and mental health of the aging individual but that no hard and fast rules can be set, because each person requires individual appraisal.

MEDICAL NEWS

ARKANSAS

State Medical Election.—The Arkansas Medical Society has recently installed Dr. T. Duel Brown, Little Rock, president; Dr. Louis K. Hundley, Pine Bluff, president-elect; Dr. John W. Smith, Little Rock, treasurer; and Dr. John J. Monfort, Batesville, secretary.

CALIFORNIA

Personal.—Dr. Frederick M. Kriete, assistant chief of preventive medical services with the State Health Department, has been appointed deputy state health director. The position was created at the last session of the Legislature. Dr. Kriete has been with the department since 1947.

Grants for Heart Disease Research.—Allocations totaling $221,669 for heart disease research have been announced by the Los Angeles County Heart Association. The grants are for support of 34 projects at Southern California School of Medicine, University of California Medical Center, College of Medical Evangelists, the Veterans Administration Center, and Cedars of Lebanon, Children's, and Los Angeles County hospitals. The majority of the studies are concerned with the cause and prevention of heart disease. Grants to University of California investigators working at the Medical Center, the VA Center, and Cedars of Lebanon Hospital total $112,927, including a $50,000 grant for the Heart Association Laboratory, where Wilfried Mommaerts, Ph.D., is studying the basic chemistry of the heart muscle.

Psychiatric Society Founded.—Twenty psychiatrists from Santa Clara and Monterey counties met at the Santa Clara County Hospital recently to officially form the Santa Clara–Monterey Counties Psychiatric Society. The purpose of this group will be to promote psychiatry in these two counties by sponsoring scientific-educational programs, by representing psychiatry in the community, and by encouraging fellowship between psychiatrists and workers in related fields. The society plans to become an affiliate society to the American Psychiatric Association. At the founding meeting a constitution was accepted and the following officers were elected: Dr. Robert A. Hall, San Jose, president; Dr. Fred Tempey, Agnews State Hospital, vice-president; Dr. Alan M. Clarke, Los Gatos, secretary-treasurer; and Drs. Raymond L. Hack, Salinas, Norman Rogers, Agnews State Hospital, and Walter J. Freeman, Los Altos, councillors.

COLORADO

Automobile Crash Injury Study.—A unique study of automobile accidents has been initiated in Colorado primarily concerned with determining the nature and specific causes of injury to occupants of passenger cars. This program, known as Automotive Crash Injury Research, has been endorsed by the House of Delegates of the Colorado State Medical Society and will constitute a coordinated effort on the part of the society and the Colorado State Patrol. The study will function for a year as part of a 15-state program coordinated by the Automotive Crash Injury Research project of the Department of Public Health and Preventive Medicine, Cornell University Medical College, New York City. The Colorado study will help to evaluate the effectiveness of specific design changes in 1956, 1957, and 1958 model automobiles, energy-absorbing steering wheels, seat belts, and interior padding. Medical and accident data-collecting methods operate in the following way: all 1956, 1957, and 1958 passenger cars involved in injury-producing accidents outside the limits of municipalities come within the scope of the study. Immediately following an accident, the Colorado State Patrol officer in charge submits to the physician or emergency room chief or coroner a special medical report form furnished by Cornell which includes a description of the extent and nature of all injuries. Completed forms are mailed to the Colorado State Medical Society. These studies are sponsored by the Armed Forces Epidemiological Board through its Commission on Accidental Trauma, with funds supplied by the Surgeon-General of the Army, by the Division of Research Grants of the United States Public Health Service and by grants to Cornell University Medical College of unrestricted funds by the Ford Motor Company and the Chrysler Corporation.

CONNECTICUT

Dr. Paul Receives Lyman Medal.—The David Russell Lyman gold medal for "outstanding productiveness and service to public welfare" was awarded to Dr. John R. Paul on May 25. The presentation was made at the 55th annual meeting of the Gaylord Farm Association in Wallingford. Dr. Paul is professor of preventive medicine in the Yale Medical School, New Haven. In 1938 he and the Yale Med-

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

ical School received the first research grant issued by the National Foundation for Infantile Paralysis. In making the presentation, Dr. Gustaf E. Lindskog, professor of surgery at Yale, said "Dr. Paul's interest in poliomyelitis and other neurotropic diseases, his outstanding accomplishments in rheumatic heart disease, appears to us to appropriately symbolize the changes and broadening emphasis now occurring at Gaylord Farm."

ILLINOIS

Chicago

Personal.—Dr. Joseph T. Meyer has received a Loyola University Alumni Citation, an engraved plaque, awarded to those whose "careers exemplify the ideals of Jesuit education." Dr. Meyer served in the Army Medical Corps, attaining the rank of captain, and after World War I he joined with his brothers, Dr. Raymond Meyer and the late Dr. Edwin Meyer, to establish a clinic on the south side. Dr. Meyer is president and chief surgeon of St. George Hospital.

New Chairman of Radiology Department.—Dr. Earl E. Barth, professor of radiology, Northwestern University Medical School, has been named chairman of the department of radiology, effective Sept. 1, to succeed Dr. Edward L. Jenkinson, who is retiring. Dr. Barth, a graduate of Northwestern Medical School, joined the faculty in 1931 as a fellow in radiology. In 1953 he was named a full professor. He is also chief consultant in radiology at the Veterans Administration Research Hospital, Chicago, a past-president of the Chicago Roentgen Society and a past-chairman of the executive council of the American Roentgen Ray Society, and now is chairman of the board of chancellors of the American College of Radiology.

Institute for Study of Congenital Heart Disease.—A Congenital Heart Institute sponsored by the Chicago Heart Association was started Sept. 1 and will continue for a minimum of 10 years. Dr. Maurice Lev has been hired as full-time investigator to devote all his time to a study of the life history and pathology of the defects of the heart. Dr. Lev will perform his investigative work in laboratory and working space provided for him in the Hektoen Institute of Chicago and the work will be done under the cooperation of the five Chicago medical schools, the Chicago Heart Center, and the health agencies of city and state. Dr. Lev plans to assemble clinical, laboratory, and pathologic data on cases of children who die of congenital heart defects. Cost of the institute will be about $50,000 a year.

Medical Associates of Chicago.—A medical facility, the Medical Associates of Chicago, has been organized by Dr. Nathaniel Calloway, professor of internal medicine, University of Illinois Medical School. This group, which has offices in the Lake Meadowbrook development, involves a collective investment of $700,000 and represents the first established group practice started by Negroes in the city with complete diagnostic facilities. The group has 14 physicians, three dentists, technicians, nurses, and office personnel, in all about 40 persons. The new offices house a pharmacy, medical diagnostic and dental laboratories. From 1951 to 1953, Dr. Calloway served as associate chief of medicine at Percy Jones Army Hospital, Battle Creek, Mich. He has served as a medical consultant to the U. S. public health service and the naval research project at the University of Illinois, and is a member of the Tuberculosis Institute of Chicago and Cook County.

KENTUCKY

State Medical Association Meeting.—The R. W. Gaines Memorial Meeting of the Kentucky State Medical Association will be held Sept. 16-19 at the Columbia Auditorium, Louisville. A panel discussion, "Hypothyroidism—Diagnosis and Management," will be moderated by Dr. Alton Ochsner, New Orleans, on Sept. 19. Color television sessions will include two symposiums: duodenal ulcer and congenital heart disease. The program includes the following topics by out-of-state speakers:

Tuberculosis in Childhood: Some Aspects of Prevention, Diagnosis and Treatment, Dr. Gardner Middlebrook, Denver.
Obstetrical Anesthesia and Analgesia, Dr. Ralph A. Reis, Chicago.
Pain as an Emotional Problem, Dr. Lawrence C. Kolb, New York City.
Role and Function of the National Eye Bank, Dr. Donald M. Shafer, New York City.
Modern Concepts in the Management of Hepatic Failure, Dr. John M. Rumball, Coral Gables, Fla.
Carcinoma of the Stomach, Dr. Alton Ochsner, New Orleans.
Preventable Errors in the Care of Orthopedic Injuries, Dr. Robert A. Knight, Memphis, Tenn.

Twelve specialty groups will present scientific programs simultaneously the afternoon of Sept. 18. Entertainment includes the President's Luncheon, at which Dr. Kenneth McFarland, Topeka, Kan., will speak on "Ropes of Gold." A special ladies' program is planned. For information write Mr. J. P. Sanford, 620 S. Third St., Louisville 2, Ky.

LOUISIANA

Graduate Medical Assembly.—The Southwest Louisiana Graduate Medical Assembly will hold its eleventh annual meeting at the Majestic Hotel, Lake Charles, Sept. 13-14. All physicians are invited to attend this meeting which is approved for category I by the American Academy of General Practice. The program includes the following topics by out-of-state speakers:

Outpatient Management of Hypertension, Dr. John Moyer, chairman, department of medicine, Hahnemann Medical College, Philadelphia.
Anxiety Heart Disease, Dr. Don Chapman, professor of medicine, Baylor University, Houston, Texas.

Common Duct Stone, Dr. Robert M. Moore, chairman, department of surgery, University of Texas, Medical Branch, Galveston.

The Interpretation of Chest Films in Pediatrics, Dr. Vincent P. Collins, professor of radiology, Baylor University College of Medicine.

The Practical Diagnosis of Bleeding Disorders, Dr. Jack Abbott, pathologist and director of laboratories, Methodist Hospital and Baylor University College of Medicine, Houston.

A panel discussion, "Diagnosis and Management of Thyroid Diseases," will be presented by Drs. Don Chapman, John Moyer, Jack Abbott, Vincent P. Collins, and Robert M. Moore. A clinico-pathologic conference and a round-table luncheon discussion also are scheduled. For information write Dr. Janie M. Topp, P. O. Box 568, Lake Charles 1, La.

MICHIGAN

Society News.—The following officers of the Michigan Allergy Society have been elected: Dr. Ernst O. Schreiber, Flint, president; Dr. Bernard Dickstein, Flint, vice-president; and Dr. Milton J. Steinhardt, Detroit, secretary-treasurer.

State Medical Society Meeting.—The 92nd annual session of the Michigan State Medical Society will be held Sept. 25-27 at the Pantlind Hotel, Grand Rapids. The annual presidential address will be given by Dr. Arch Walls, at the officers' night, after which Governor G. Mennen Williams will also present an address. The program includes special discussion conferences and the following panel discussions: Treatment of Polyps of the Rectum and Colon; The Problem of the Destructive Impulse in the Practice of Medicine; What's New in Heart Disease; and Patient-Centered Medical Care. The fifth Beaumont Lecture, "Cancer of the Lower Bowel: The Adenoma Carcinoma Sequence," will be presented by Dr. Raymond J. Jackman, head, section of proctology, Mayo Clinic, Rochester, Minn. Technical and scientific exhibits are scheduled. Entertainment includes the officers' night dinner-dance Sept. 25. Mr. Walter P. Reuther, Detroit, will speak on "Medicine and Labor in These Changing Times" the afternoon of Sept. 25. For information write Dr. L. F. Foster, 606 Townsend Street, Box 539, Lansing 15, Mich.

MISSOURI

Society News.—The following officers were elected by the members of the St. Louis Society of Anesthesiologists: president, Dr. Thomas Culkin; vice-president, Dr. Harry Sammons; secretary, Dr. Richard E. Hanna; and treasurer, Dr. Jean Merz.

Personal.—Dr. Walter J. Burdette professor of clinical surgery, St. Louis University School of Medicine, and director, St. Louis University Surgical Service at Veterans Hospital, has gone to Tokyo to visit medical and research institutions in Japan. One objective of the trip is in connection with the studies he has been conducting at the university on a hormone in relation to cancer. Following his stop in Japan Dr. Burdette will visit and lecture at medical and research centers in Thailand, India, Lebanon, Germany, France, Greece, and Turkey.—Dr. Norman Tobias, dermatologist of St. Louis, has returned from an extended trip to the Far East, where he lectured before the Tokyo, Bangkok, and Manila Medical Societies under the auspices of the World Medical Association.

NEBRASKA

General Practice Meeting in Omaha.—The annual meeting of the Nebraska Chapter of the American Academy of General Practice will be held Sept. 13-14 at the Fontenelle Hotel, Omaha. The presidential address will be given by Dr. Thomas D. Fitzgerald. A panel discussion with live television interviews on a closed-circuit direct from the Nebraska Psychiatric Institute on "Psychiatric Aspects of Surgical Practice" will be held on the morning of Sept. 13, with Dr. L. C. Strough serving as moderator. A luncheon program Sept. 13 includes addresses by Drs. Paul Read, president, Douglas County Medical Society; R. R. Best, president, Nebraska State Medical Society; and M. E. Phelps, president, American Academy of General Practice. Guest speaker at the banquet to be held the evening of Sept. 14 will be Dr. H. E. Campbell, Denver, member of the American Medical Association's Traffic Committee, whose topic is "Safety on Our Highways." A special ladies' program is planned. For information write Dr. C. R. Brott, Chairman, Program Committee, 2124 Elk St., Beatrice, Neb.

NORTH CAROLINA

Grant for Pituitary Study.—A grant of $31,050 from the U. S. Public Health Service has been made to Dr. Gordon Dugger, assistant professor of surgery, University of North Carolina School of Medicine, Chapel Hill, to be used for the study of the effects of pituitary gland operations on patients with cancer. Associated with Dr. Dugger in the research are Drs. James Newsome and Judson Van Wyk. Dr. Dugger was trained in neurosurgery at the Montreal Neurological Institute of Montreal, Canada.

GENERAL

Pediatricians Meeting in Chicago.—The 26th annual meeting of the American Academy of Pediatricians will be held Oct. 5-10 at the Palmer House, Chicago. Two symposiums are scheduled for the general sessions: current developments in infant nutrition, and animals and diseases. Three panel discussions are also scheduled: problems of the hospitalized child, iatrogenic disease, and congenital metabolic disease. Round-table discussions will be held Oct. 7 and 8. The Mead Johnson award presentation "Steroid Biogenesis in the Adrenal Cortex of Man" and "Some

Studies on the Biochemistry of Connective Tissue," will be given by Drs. Alfred M. Bongiovanni and Walter R. Eberlein, of Philadelphia, and Dr. Albert Dorfman, Chicago, respectively. The Borden award presentation will be given by Dr. Arild E. Hansen, Galveston, Texas, on "Essential Fatty Acids in Infant Nutrition." A special quiz session will be held Oct. 8 under the direction of Dr. Robert B. Lawson, Miami, Fla. Scientific and commercial exhibits will be shown. A ladies' program is planned. Entertainment includes the annual banquet. For information write the Executive Officer, American Academy of Pediatricians, 1801 Hinman Ave., Evanston, Ill.

International Postgraduate Medical Association Meeting.—The 42nd International Scientific Assembly of the Interstate Postgraduate Medical Association will be held Sept. 30-Oct. 3 at the Palmer House, Chicago. Forty papers are scheduled for presentation. Three symposiums will be held on the following topics: what's new in obstetrics, surgery, and steroids; trauma; and the proper selection of cases for heart surgery. The following presentations will be made by Canadian speakers:

Abnormal Vaginal Bleeding in the Menopause, Dr. Newell Philpott, professor of obstetrics and gynecology, McGill University Faculty of Medicine, Montreal, Canada.

Clinical Management of the Allergic States, with Special Reference to Long-Term Steroid Therapy, Dr. Bram Rose, professor of medicine, McGill University Faculty of Medicine, Montreal.

A Neuro-Surgeon Looks at "Strokes," Dr. E. Henry Botterell, associate professor of surgery, University of Toronto, Canada.

The guest speaker at the annual dinner will be Kenneth McFarland, Ph.D., Topeka, Kansas, whose topic will be "Ropes of Gold." For information write Interstate Postgraduate Medical Association, Box 1109, Madison 1, Wis.

Radiological Research Awards.—The James Picker Foundation has announced two awards in the field of radiological research, in addition to those made public in June. As a part of its efforts in advancing the science of radiology, the foundation supports research grants, fellowships, and grants for scholars. These awards are made on recommendation of the National Academy of Sciences–National Research Council.

A research grant has been made to the University of Saskatchewan, Saskatoon, Canada, to permit continuation for a third year of Dr. Sidney P. Traub's studies on x-ray changes produced by increased pressure from within the skull. Dr. Traub is assistant professor of diagnostic radiology at the university College of Medicine.

The reappointment of Dr. Hans Ludin, of New York City, as a James Picker Foundation Fellow in Radiological Research is also announced. Under his fellowship, which began in 1956, Dr. Ludin has been studying the use of special techniques to visualize the pancreas on x-ray examination. This work is being carried out in the department of radiology, New York Hospital, New York City, under the guidance of Dr. John A. Evans.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Society News.—The following officers of the **American College of Physicians** have been installed: president, Dr. Richard A. Kern, Philadelphia; president-elect, Dr. Dwight L. Wilbur, San Francisco; first vice-president, Dr. Herbert K. Detweiler, Toronto; second vice-president, Dr. Charles A. Doan, Columbus, Ohio; third vice-president, Dr. Lemuel C. McGee, Wilmington, Del.——The newly elected officers of the **World Federation of Neurosurgical Societies** are: Dr. Paul C. Bucy, Chicago, president; Dr. E. Harry Botterell, Toronto, Canada, vice-president; Dr. Bronson S. Ray, New York, secretary-general; Dr. William B. Scoville, Hartford, Conn., assistant secretary-general; Dr. Barnes Woodhall, Durham, N. C., treasurer; Dr. Wallace B. Hamby, Buffalo, N. Y., assistant treasurer; and Dr. David L. Reeves, Santa Barbara, Calif., editor of the transactions. Dr. Percival Bailey, of Chicago, Dr. Wilder Penfield, of Montreal, Canada, Dr. H. Olivecrona, of Stockholm, Sweden, Dr. Paul Martin, of Brussels, Belgium, Dr. D. Petit-dutaillis, of Paris, France, and Sir Geoffrey Jefferson, of Manchester, England, are honorary presidents.——At the 67th annual meeting of the **American Pediatric Society** the following officers were elected for 1958: president, Dr. A. Ashley Weech, Cincinnati; vice-president, Dr. Alton Goldbloom, Montreal, Canada; secretary-treasurer, Dr. Aims C. McGuinness, Washington, D. C.; recorder-editor, Dr. Stewart H. Clifford, Brookline, Mass.——The following officers of the **Pacific Northwest Society of Plastic and Reconstructive Surgery** have been installed: Dr. Ernest E. Banfield, Tacoma, president; Dr. Carl E. Chism, Seattle, president-elect; Dr. Verner V. Lindgren, Portland, vice-president, and Dr. Willard D. Rowland, Portland, secretary-treasurer.

EXAMINATIONS AND LICENSURE

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Part I.* Various Centers, Sept. 3-4. Sec., Dr. John B. Hubbard, 133 South 36th St., Philadelphia 4.

MEDICAL SPECIALTY BOARDS

American Board of Anesthesiology: *Oral.* Washington, Oct. 28-Nov. 1. Various locations in the United States and Canada, July 18. Final date for filing application is Jan. 18. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15.

American Board of Dermatology: *Oral.* Baltimore, Oct. 11-13. Final date for filing application was April 1. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written.* Oct. 21. *Oral.* Los Angeles, Sept. 11-14. Final date for filing applications was Feb. 1. Exec. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Chicago, Jan. 2. *Part II.* Chicago, May 7-17. Final date for filing application is Spetember 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6.

American Board of Ophthalmology: *Oral.* Chicago, Oct. 7-11. *Written.* January 1958. Final date for filing application was July 1. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: Parts I and II, New York City, Jan. 29-31, 1958. Final date for filing application is August 15. Sec., Dr. Sam W. Banks, 116 South Michigan Avenue, Chicago 3.

American Board of Otolaryngology: Chicago, Oct. 7-11. Final date for filing application was in April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Oral and Written. Pathologic Anatomy and Clinical Pathology.* New Orleans, Sept. 26-28. Final date for filing application is August 15. Sec., Dr. Edward B. Smith, Indiana University Medical Center, Indianapolis 7.

American Board of Pediatrics: *Oral.* Chicago, Oct. 11-13. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Plastic Surgery: *Oral and Written Examination.* San Francisco, Oct. 31-Nov. 2. Final date for filing case reports was July 1. Corresponding Sec., Miss Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *In Public Health. Oral and Written.* Cleveland, Nov. 7-9. Sec., Dr. Thomas F. Whayne, 3438 Walnut St., Philadelphia.

American Board of Proctology: *Oral and Written. Parts I and II. September.* Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: New York, Dec. 16-17. San Francisco, March 17-18. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S. W., Rochester Minn.

American Board of Radiology: Washington, Sept. 23-28. Final date for filing application was June 1. Chicago, May 20-24. Final date for filing application is Jan. 1, 1958. Sec., Dr. H. Dabney Kerr, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part II.* Buffalo, Sept. 23-24; New Haven, Oct. 21-23; Indianapolis, Nov. 18-19; Cincinnati, Dec. 16-17; New Orleans, Jan. 13-14; Durham, N. Car., Feb. 10-11; Baltimore, March 10-11; Chicago, May 12-13; Los Angeles, June 16-17 and Portland, Oregon, June 20-21. Sec., Dr. John B. Flick, 225 So. 15th St., Philadelphia 2.

American Board of Urology: *Written examination.* Various cities throughout the country. *Pathology and Oral Clinical.* February 1958. Location not decided. Exec. Secretary, Mrs. Ruby L. Griggs, 30 Westwood Road, Minneapolis 16.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, Sept. 6, and the closing date for registration was July 1, 1957. Sec., Dr. William H. Tuttle, 1151 Taylor Ave., Detroit 2.

GOVERNMENT SERVICES

AIR FORCE

Consultants Visit Medical Installations.—The following four consultants to the surgeon general recently visited Air Force medical installations in Europe, the Far East, and Alaska. They rendered services on problem cases in their specialties and conducted lectures and teaching sessions at various medical installations.

Dr. Francis M. Forster, dean, Georgetown University School of Medicine, and consulant in neurology, visited installations in England, France, Germany, Morocco, and Libya.

Dr. Jasper Lamar Callaway, professor of dermatology and syphilology, Duke University School of Medicine, and consultant in dermatology, visited installations in Japan, Korea, Okinawa, the Philippine Islands, and Taiwan.

Dr. Sidney S. Chipman, professor of maternal and child health, University of North Carolina School of Public Health, and consultant in pediatrics, and Dr. Marvin E. Chapin, professor of oral surgery, University of North Carolina, and consultant in oral surgery, both visited installations in Alaska.

Personal.—At the School of Aviation Medicine in Texas, Dr. Lawrence E. Lamb has been appointed chief of the department of internal medicine. Dr. Lamb did research in Switzerland in 1954 on electrocardiography as a fellow of the American Heart Association. He is the author of a forthcoming book. "Fundamentals of Electrocardiography and Vectorcardiography."

Conduct Awards Made.—The following Air Force medical officers have been awarded the Legion of Merit for exceptionally meritorious conduct in the performance of outstanding service: Col. Manah R. Halbouty, commander, 3605th U. S. A. F. Hospital, Ellington Air Force Base, Texas; Col. Robert A. Patterson, surgeon, Eastern Air Defense Force, Stewart Air Force Base, New York; Col. Philip P. Pease, commander, 7272nd U. S. A. F. Hospital, Wheelus Air Force Base, Libya.

ARMY

Wings for Army Aviation Medical Officers.—First award of silver Army aviation wings to 50 Army Medical Corps officers marks the newest development in the Army aviation medicine program according to Major Gen. Silas B. Hays, surgeon general of the Army. The new badge has the caduceus superimposed on the shield of the Seal of the United States centering the wings.

Officers designated to wear these wings already have non-crew-member flying status and pay, and they also perform clinical duties for non-flying personnel. They are officially recognized as being qualified to conduct medical examinations for flying, to exercise supervision over the health of flying personnel, and to furnish medical advice related to Army aviation. They receive their aviation medical training at the Air Force School of Aviation Medicine, Randolph Air Force Base, Texas, or at the Navy School of Aviation Medicine, Pensacola, Fla. On completion of either of these courses, the Army graduates are sent to the Army Aviation School, Fort Rucker, Ala., for applicatory instruction in Army aviation medical practice.

The 50 medical officers awaiting their wings are to be found with infantry, armored, and airborne divisions, with station medical complements responsible for the care of significant concentrations of Army aviators, and with a variety of special Army aviation activities. They are stationed in Germany, Japan, Korea, the Territory of Hawaii, and the Canal Zone. They are serving at installations across the United States from Fort Lewis, Wash., to Fort Benning, Ga., from the Army Medical Research Laboratory, Fort Knox, Ky., to the Walter Reed Army Medical Center.

Personal.—Col. Joseph P. Russell has been named Post Surgeon and Commanding Officer of the Army Hospital at Fort Leavenworth, Kan., succeeding Col. Norman Anderson.

VETERANS ADMINISTRATION

Study of Sarcoidosis.—The project sponsored by the Veterans Administration to investigate the etiology of sarcoidosis will be carried on in five hospitals which will contribute information on the environment, occupation, eating habits, and self-medication of patients affected by this disease. The central office research team is composed of Dr. Martin M. Cummings, director of research service; Dr. Edward Dunner, secretary of the Veterans Administration–armed forces committee on chemotherapy of tuberculosis; Dr. Richard H. Schmidt Jr., tuberculosis service; and J. H. Williams of research statistics. Seventeen hundred cases of sarcoidosis were diagnosed in these hospitals between the years 1949 and 1956.

Personal.—Dr. Thomas J. Ready, director, professional services, VA Hospital, Providence, R. I., was transferred as manager of the VA Hospital at Washington, D. C., to fill the vacancy created by the retirement of Dr. Edwin J. Rose on June 30.——Dr. Kenneth W. Brown, director, professional services, VA Hospital, Omaha, has been appointed to the combined position of manager and director of professional services at the VA Hospital, Clarksburg, W. Va., to fill the vacancy created by the retirement of Dr. Louis M. Hohman on June 26.——Dr. Abraham M. Kleinman, director of professional services, VA Hospital, Brooklyn, N. Y., has been appointed manager of the VA Hospital in the Bronx, New York City, a 1,372-bed general medical and surgical facility.——Dr. Richard B. Bean, area director of professional services, VA Area Medical Office, Boston, had become manager of the VA Hospital at Boston, replacing Dr. George P. Denny who retired June 30, 1957. The hospital is a 920-bed general medical and surgical facility.

Mental Hospital as a Therapeutic Community.—The Veterans Administration is trying to develop the mental hospital into a therapeutic community that will prepare recovering patients for the life they will lead outside the hospital. A pilot program is under way at the VA Hospital in St. Cloud, Minn.

Dr. Jesse F. Casey, VA director of psychiatry and neurology, said the nub of the St. Cloud program is a "motivation unit," directed by Dr. W. R. Coutant. This unit consists of a ward with 80 patients selected from the entire hospital and a foster home program under which 55 patients live outside the hospital on a trial basis. Patients living in the ward are encouraged to become friends, to work at jobs in the hospital, to attend recreational activities together, and to live much as they would outside the hospital. Once a week they gather in groups of 10 to talk about their feelings and fears of returning to the community, Dr. Casey said, and efforts are made by the staff to allay the fears and build up the patients' trust and confidence. When the ward patients are ready, they are placed with families in the St. Cloud area.

Only about 10% of those in foster homes have returned for further hospitalization, and in the two years since the motivation unit was established the number of discharges from the hospital has risen from less than 300 a year to about 600. The staff of the unit includes also a social worker, a psychiatric nurse, a clinical psychologist, and the hospital's vocational counselor.

Former Long-term Patients Now at Work.—Increasing numbers of long term patients are able to leave VA hospitals to take paying jobs under a new vocational guidance program. During the first three months of 1957, a total of 2,825 patients were placed in jobs outside the hospital by the VA's vocational counseling service and through state and local agencies. The figure includes veterans who have recovered from mental illness, tuberculosis, and other seriously disabling illnesses.

Study of Fungus Pulmonary Diseases.—Comprehensive studies of two lung diseases (histoplasmosis and coccidioidomycosis), which simulate tuberculosis, have been started by the VA in cooperation with the Armed Forces, the VA announced July 23. The studies are aimed at testing the effectiveness of new drugs which show promise in treatment.

Tentative case registries of some 500 patients with histoplasmosis or coccidioidomycosis in VA hospitals during the past two years have been established for study. Diagnoses are being substantiated by laboratory tests.

The histoplasmosis study is being carried out at seven VA hospitals, and at the Naval Hospital, St. Albans, N. Y., and Fitzsimons Army Hospital, Denver.

Central laboratories for the study have been established at the Kennedy Division of the VA's Memphis Hospital, and at Walter Reed Army Hospital in Washington, D. C.

Fourteen VA and Armed Forces hospitals are making the study of coccidioidomycosis. The central laboratory for the coccidioidomycosis study is at the VA's San Fernando, Calif., Hospital.

PUBLIC HEALTH SERVICE

Program to Encourage Research on Aging.—A new research approach to the health problems of older persons was launched on Aug. 1, as Surgeon General Leroy Burney announced a $306,922 award to Duke University in a special ceremony on the university campu at Durham, N. C. The award is the first grant in th Public Health Service's new program to encourage establishment of research centers in which many departments of a university, and the health and relate agencies of a community will cooperate in studyin various aspects of aging.

The program at Duke University has four main objectives: (1) To develop a Center for Aging Researc based on a university-wide effort. (2) To suppo fundamental research concerned with health problen of aging and to include relevant research contributio from the social and behavioral sciences and relate fields. (3) To train investigators interested in th problems of aging. (4) To foster a regional resour for the dissemination of scientific knowledge in th field of aging.

The Public Health Service program to encoura such research is sponsored by the Center for Researc on Aging at the National Institutes of Health, Bethesda, Md., established in October, 1956, under th direction of Dr. G. Halsey Hunt.

Research on Cerebral Vascular Disease.—The launching of a nationwide cooperative research program o cerebral vascular disease has been announced by th surgeon general. Ten medical research centers in nin states have already joined in the program, and it expected that many more institutions will ultimatel participate. The program, which is expected to ru several years, is under the auspices of the Nation Institute of Neurological Diseases and Blindness the National Institutes of Health. The program w made possible by grants to the participating orga zations, recommended by the National Advisor Neurological Diseases and Blindness Council. Th program is concerned specifically with patients suffe ing from cerebral vascular disease involving hemo rhage, blood clots, aneurysms, and malformations the arteries or veins of the brain. It has been estimate that as many as 1,800,000 living Americans have su fered cerebral strokes at one time or another and th deaths due to such strokes number about 175,000 annually. This research is expected to shed new light o the nature and causes of strokes and to open the wa to more effective treatment.

DEATHS

Moorhead, John Joseph, Millbrook, N. Y.; born in New York City July 15, 1874; New York University Medical College, New York City, 1897; professor emeritus of surgery at the New York University Post-Graduate Medical School in New York City; an associate member of the American Medical Association; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; decorated for his service in France in World War I; received the Croix de Guerre and the Cross of the Legion of Honor; his own country awarded him the Gold Medal of Honor, the Distinguished Service Cross, and the Distinguished Service Medal; presented with a medal by the Honolulu County (Hawaii) Medical Society for helping care for the wounded following the Japanese attack on Pearl Harbor Dec. 7, 1941, when he was in Honolulu as the guest of the society; in 1944 retired as medical director of the New York City Transit Company; consultant, New York Post-Graduate Medical School and Hospital, Mother Cabrini Memorial and Harlem hospitals in New York City, Yonkers (N. Y.) General Hospital, Nyack (N. Y.) Hospital, Caledonian Hospital, Brooklyn, New Rochelle (N. Y.) Hospital, Mary Immaculate Hospital, Jamaica, Rockland State Hospital in Orangeburg, Rahway (N. J.) Hospital, Fitkin Memorial Hospital, Neptune, N. J., and the All Souls Hospital, Morristown, N. J.; in 1941 received the honorary degree of doctor of science from New York University; author of "Clinical Traumatic Surgery"; died July 1, aged 82, of acute dilatation of the heart.

Larsen, Reuben Leonard, Lieut. Commander, U. S. Navy, retired, Seattle; born on Jan. 25, 1890; Northwestern University Medical School, Chicago, 1916; service member of the American Medical Association; veteran of World War I; commissioned in the regular Navy in 1917; placed on the retired list November, 1920, due to physical disability; at the outbreak of World War II requested recall to active duty and on Dec. 26, 1941, reported to the Naval Air Station, Corpus Christi, Texas, for active duty; released to inactive duty on Oct. 20, 1945; during his more than seven years active service, served with Naval medical department facilities throughout the United States and abroad and in ships of the fleet; died in the U. S. Naval Hospital, Bremerton, June 21, aged 67, of hemopericardium and myocardial infarction.

Comfort, Charles Williams Jr. ⊕ New Haven, Conn.; born in Philadelphia in 1885; Yale University School of Medicine, New Haven, 1911; served in World War I, and was awarded the Distinguished Service Cross and the French Croix de Guerre; during World War II was division surgeon and commanded the 118th Medical Regiment of the 43rd division, National Guard; retired with the rank of colonel in 1946; formerly secretary of the Connecticut State Medical Society; member of the city welfare board; on the staff of the Grace-New Haven Community Hospital; died in the Veterans Administration Hospital, Rocky Hill, May 6, aged 71, of coronary thrombosis.

Higgins, William Harrison ⊕ Richmond, Va.; born in Stanford, Ky., in 1883; Johns Hopkins University School of Medicine, Baltimore, 1908; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Clinical and Climatological Association; past-president of the Richmond Heart Association, Richmond Academy of Medicine, and the Richmond Board of Health; formerly on the faculty of the Medical College of Virginia; on the staff of the Medical College of Virginia, Hospital Division; consultant, St. Elizabeth's Hospital; died June 8, aged 73, of cerebral hemorrhage.

Jesberg, Simon, Los Angeles; born in Franklin, Iowa, Sept. 16, 1886; College of Physicians and Surgeons, Los Angeles, 1913; an associate member of the American Medical Association; member of the American Broncho-Esophagological Association; member and formerly vice-president of the American Laryngological, Rhinological and Otological Society; specialist certified by the American Board of Otolaryngology; formerly on the faculty of the University of Southern California School of Medicine; served in France during World War I; associated with the Eye and Ear Hospital; died June 24, aged 70, of cerebral hemorrhage.

Alley, Ralph Martin ⊕ Orofino, Idaho; born in Benwood, W. Va., Feb. 9, 1901; Jefferson Medical College of Philadelphia, 1927; member of the American College of Chest Physicians and the American Trudeau Society; veteran of World War II; at one time associated with the Indian Service; served as superintendent of the State Tuberculosis Sanatorium in Socorro, N. M., and the Shawnee (Okla.) Indian Sanatorium, and as chief of the student health service, University of Idaho in Moscow; on the staff of the State Hospital, where he died May 10, aged 56, of coronary occlusion.

Christenberry, Henry Eddie ⊕ Knoxville, Tenn.; born in Oliver Springs, Tenn., Sept. 12, 1884; University of Tennessee Medical Department, Nashville, 1907; specialist certified by the American Board of Otolaryngolo-

---

⊕ Indicates Member of the American Medical Association.

gy; fellow of the International College of Surgeons; served as member and chairman of the city school board; at one time mayor of Lonsdale; the Christenberry Junior High was named for him; on the staff of the Knoxville General Hospital; medical director and owner of Dr. H. E. Christenberry Eye, Ear, Nose and Throat Infirmary; died in the East Tennessee Baptist Hospital May 20, aged 72.

Mellen, Richard Hager ⊕ Colorado Springs, Colo.; born in Middlebury, Vt., Oct. 23, 1909; Harvard Medical School, Boston, 1935; certified by the National Board of Medical Examiners; specialist certified by the American Board of Orthopedic Surgery; member of the Clinical Orthopaedic Society, American Academy of Orthopaedic Surgeons, and the American Society for Surgery of the Hand; veteran of World War II; chief of staff, Glockner Penrose Hospital; on the staffs of the Memorial and St. Francis hospitals; died June 8, aged 47, of coronary occlusion and myocardial infarction.

Robertson, Roy Lamar ⊕ Monroe, La.; born in Rayville, La., Dec. 14, 1918; Emory University School of Medicine, Atlanta, 1942; interned at the Peter Bent Brigham Hospital in Boston; served a residency at the Grady Memorial Hospital in Atlanta, Ga.; formerly on the faculty of the Emory University School of Medicine in Atlanta; specialist certified by the American Board of Surgery; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; veteran of World War II; on the staffs of the E. A. Conway Memorial and St. Francis hospitals; died in Shreveport May 29, aged 38.

Copeland, N. Newall, Pittsfield, Mass.; born in 1896; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1922; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; chief of surgical staff of Pittsfield General Hospital; an associate surgeon at St. Luke's and Hillcrest hospitals; veteran of the Canadian Army during World War I; past-president of the Berkshire District Medical Society and the Pittsfield Surgical Club; vice-president of the Union Federal Savings and Loan Association; died May 22, aged 60.

Hill, Robert Henry ⊕ Newark, N. J.; Columbia University College of Physicians and Surgeons, New York City, 1926; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; on the staffs of the Presbyterian Hospital and the Harrison S. Martland Medical Center; on the courtesy staffs, Hospital of St. Barnabas and for Women and Children, St. James and St. Michael's hospitals and Babies Hospital-Coit Memorial; consultant, Newark Eye and Ear Infirmary; died June 24, aged 63, of coronary arteriosclerosis.

Beebe, Linn Clair, Hamilton, N. Y.; Baltimore Medical College, 1895; veteran of World War I; during World War II a member of the County Medical Committee for Procurement and Assignment; served as cou coroner, postmaster, health officer, and head of department of health, Colgate University; died in *Community Memorial Hospital* June 12, aged 83, hiccoughs of three weeks duration, associated esophageal hernia and diverticulum of the term part of the esophagus.

Blair, William W., Pittsburgh; Hahnemann M College and Hospital of Philadelphia, 1889; profe emeritus of ophthalmology at the University of burgh School of Medicine; specialist certified by American Board of Ophthalmology; member of American Academy of Ophthalmology and Otol gology; fellow of the American College of Surg associated with the Eye and Ear Hospital an Margaret Memorial Hospital; died June 12, age of heart disease.

Bliss, Guy Luvergne, Claremont, Calif.; Rush Me College, Chicago, 1908; *an associate member o* American Medical Association; specialist certifie the American Board of Pediatrics; member o American Academy of Pediatrics; fellow of the A ican College of Physicians; formerly practiced in Beach, where he was associated with the Se Memorial, Long Beach Community, and St. M Long Beach hospitals; died June 2, aged 79, of nary disease.

Simon, Arthur R. ⊕ Sarasota, Fla.; Indiana Univ School of Medicine, Indianapolis, 1908; memb the *Radiological Society of North America* an Indiana State Medical Society; specialist certifie the American Board of Radiology; formerly prac in La Porte, Ind., where he was on the staffs o Holy Family Hospital and the *Fairview Hos* died in the *Memorial Hospital May* 1, aged 7 rupture of dissecting aneurism of the superior me teric artery.

Ahlbrandt, Charles G. C., Kirkwood, Mo.; Miss Medical College, St. Louis, 1895; died June aged 81.

Alford, Leland Barton ⊕ St. Louis; Washington versity School of Medicine, St. Louis, 1912; asso professor of neurology and psychiatry at St. University School of Medicine; served on the fa of his alma mater; member of the American Ps atric Association; veteran of World War I; assoc with St. Mary's Group of Hospitals, St. Louis Hospital, and the Barnes Hospital, where he died 14, aged 71, of acute myocardial infarction.

Ames, George Chester ⊕ Hollis, N. Y.; University Bellevue Hospital Medical College, New York 1924; on the staff of the Mary Immaculate Hos Jamaica; died in Amityville May 11, aged 6 coronary thrombosis.

Anderson, Edgar Walker ✠ Conroe, Texas; University of Arkansas School of Medicine, Little Rock, 1928; died in the Methodist Hospital, Houston, May 11, aged 55.

Anderson, Walter Marius ✠ Lompoc, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1929; member of the American Academy of General Practice; specialist certified by the American Board of Internal Medicine; on the staffs of the Santa Barbara (Calif.) Cottage Hospital and the Lompoc Hospital; died April 10, aged 53, of coronary disease.

Angus, Catherine Isabel, New York City; University of Wisconsin Medical School, Madison, 1934; on the staff of the St. Luke's Hospital; for many years physician in the Long Lines Department of the American Telephone and Telegraph Company; died in the University Hospital June 17, aged 48.

Arne, James A., Marion, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1922; member of the Massachusetts Medical Society; on the staff of the Lawrence Memorial Hospital in Medford; died in the Tobey Hospital, Wareham, May 5, aged 61, of coronary occlusion.

Ashworth, Robert Fraser ✠ Eclectic, Ala.; Hospital College of Medicine, Louisville, Ky., 1903; veteran of World War I; member of the American Urological Association; died in East Tallassee May 8, aged 74, of cerebral hemorrhage, arteriosclerosis and chronic myocarditis.

Babcock, Jay Blaine, Los Angeles; University of Nebraska College of Medicine, Omaha, 1925; veteran of World War I; at one time superintendent of the Hastings (Neb.) State Hospital; died May 25, aged 59, of peritonitis and cholecystitis.

Baber, James H., Huntington, W. Va.; University of Louisville (Ky.) Medical Department, 1895; an associate member of the American Medical Association; died June 11, aged 82.

Barcroft, John Woolverton, Waldport, Ore.; University of Oregon Medical School, Portland, 1919; also a graduate in pharmacy; died May 13, aged 68, of arteriosclerotic heart disease.

Barnwell, Columbus Hershel ✠ Chattanooga, Tenn.; Northwestern University Medical School, Chicago, 1933; specialist certified by the American Board of Urology; member of the American Urological Association; fellow of the American College of Surgeons, veteran of World War II; associated with the Baroness Erlanger and Memorial hospitals; accidentally drowned in a pond on his farm on Little Sand Mountain near Summerville, Ga., June 2, aged 52.

Bass, Farris Euestus, Lebanon, Tenn.; Meharry Medical College, Nashville, 1924; a veteran of World War I; died June 10, aged 65, of hypertension.

Beatty, Ernest Nutter ✠ Santa Barbara, Calif.; University of Cincinnati College of Medicine, 1920; member of the Ohio State Medical Association; formerly practiced in Cincinnati, where he served as president of the Cincinnati Obstetrical Society and as a member of the staffs of St. Francis and Deaconess hospitals; died in Louisville, Ky., June 8. aged 62.

Beck, Henry Walter ✠ Gray, Maine; University of Vermont College of Medicine, Burlington, 1927; veteran of World War I; on the courtesy staffs of the Central Maine General Hospital, Lewiston, and the Mercy Hospital and Maine Eye and Ear Infirmary in Portland; served two terms on the school board; died June 4, aged 63, of cancer of the liver.

Becker, Morris R., Cambridge, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1933; died June 10, aged 50.

Beckman, George Edwin ✠ Jacksonville, Fla.; Medical College of South Carolina, Charleston, 1909; specialist certified by the American Board of Anesthesiology; died in St. Vincent's Hospital March 27, aged 77, of cerebral hemorrhage, hypertension and chronic interstitial nephritis.

Benson, Iver Simeon, Portland, Ore.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; died May 23, aged 75.

Berrey, Ivan Columbus ✠ Birmingham, Ala.; Rush Medical College, Chicago, 1927; served on the faculty of Medical College of Alabama; on the staffs of the University and Baptist hospitals; died April 26, aged 58, of carcinoma of the pancreas.

Bickel, John Edward ✠ Fort Wayne, Ind.; Medical College of Indiana, Indianapolis, 1897; member of the staff, St. Joseph's Hospital, where he died June 23, aged 83, of coronary thrombosis and myocardial infarction.

Blair, Ezekiel Slaughter ✠ Gadsden, Ala.; University of Nashville (Tenn.) Medical Department, 1910; died May 28, aged 76, of bronchopneumonia.

Bockhorst, Arthur L., Milwaukee; Kansas City (Mo.) Medical College, 1899; died in the Milwaukee County Hospital June 24, aged 82, of diabetes mellitus.

Boddie, Julian Franklin, Milledgeville, Ga.; Meharry Medical College, Nashville, Tenn., 1913; associated with the Baldwin County Hospital, where he died June 18, aged 66, of cerebral hemorrhage.

Bondar, H. Kelliher, Brooklyn; McGill University Faculty of Medicine, Montreal, Quebec, Canada, 1932; member of the American Psychiatric Association: specialist certified by the American Board of Psychiatry and Neurology; associated with the Cumberland and St. John's Episcopal hospitals; died in the Queens General Hospital, Jamaica, May 25, aged 49.

Brady, Rolland Roy ⊛ Ainsworth, Neb.; University of Nebraska College of Medicine, Omaha, 1931; member of the American Academy of General Practice; on the staff of the Ainsworth Clinic and Hospital; died in Omaha June 28, aged 53.

Brady, Richard Randall, Miles City, Mont.; University of Nebraska College of Medicine, Omaha, 1925; lieutenant colonel in the medical corps, Army of the United States; surgeon of the U. S. Army's Neurnberg, Germany, sub-area; died in Berchtesgaden, Germany, May 1, aged 56, of coronary disease.

Breslin, Robert Henry, Warwick, R. I.; College of Physicians and Surgeons, Baltimore, 1915; member of the Rhode Island Medical Society; veteran of World War I; on the staffs of the Roger Williams General Hospital and St. Joseph's Hospital, where he died June 25, aged 68.

Bruninghaus, Charles Walter, Worcester, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1915; veteran of World War I; died May 29, aged 76, of coronary artery disease.

Burnes, Eugene Howard, Rochester, N. Y.; Albany Medical College, 1908; an associate member of the American Medical Association; member of the American Academy of General Practice; past-president of the Rochester Pathological Society; veteran of World War I; during World War II chairman of Draft Board number 550; served on the staffs of St. Mary's Hospital and the Highland Hospital, where he died May 20, aged 72, of acute cardiac dilatation.

Burt, Elmer Gordon ⊛ Magnolia, Ark.; University of Arkansas School of Medicine, Little Rock, 1932; member of the American Academy of General Practice; veteran of World War II; died in the City Hospital April 26, aged 49, of a heart attack.

Butler, John Culbertson ⊛ Laurel, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; veteran of World War I; died in the Veterans Administration Center, Biloxi, May 8, aged 79, of emphysema.

Butzow, Theodore Frederick, San Diego, Calif.; Rush Medical College, Chicago, 1897; veteran of World War I; died in the Mercy Hospital May 31, aged 86, of fracture of the hip and pneumonia.

Chaffin, Emory Franklin ⊛ Toccoa, Ga.; Atlanta Medical College, 1914; died in the Hall County Hospital, Gainesville, May 21, aged 71, of a heart attack.

Chambers, Dorsey Perry, Stilwell, Okla.; Barnes Medical College, St. Louis, 1896; died in the City Hospital May 6, aged 84, of cerebral hemorrhage.

Child, Florence Chapman, Deerfield Beach, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1909; died in the North Broward General Hospital, Fort Lauderdale, March 30, aged 71, of carcinoma of the breast with metastases.

Cohen, Emanuel Samuel ⊛ Redwood City, Calif.; C lumbia University College of Physicians and Surgeo New York City, 1943; certified by the National Bo of Medical Examiners; specialist certified by t American Board of Internal Medicine; served as a sistant clinical professor of medicine at the Univers of California School of Medicine in San Francisc veteran of World War II; on the staff of the Sequo Hospital; died May 31, aged 37.

Clark, Carl George, Burlington, Iowa; State Unive sity of Iowa College of Homeopathic Medicine, Io City, 1905; died in St. Francis Hospital April 17, ag 80, of cardiovascular renal disease.

Cleere, Reuel C., Danville, Ala.; Birmingham Medi College, 1909; died in the Bryce Hospital, Tuscaloo May 1, aged 72.

Conley, Byron Richard, Salyersville, Ky.; Univers of Louisville (Ky.) Medical Department, 1907; me ber of the Kentucky State Medical Association; d in Ashland May 3, aged 74, of nephritis.

Cooper, Thomas Logan ⊛ Logansport, Ind.; Univ sity of Pittsburgh School of Medicine, 1912; on staffs of St. Joseph's Hospital and the Memorial H pital, where he died May 20, aged 74.

Crawford, Lewis B., New Iberia, La.; Medical Dep ment of Tulane University of Louisiana, New Orle 1905; fellow of the American College of Surge associated with the Iberia General Hospital, where died May 17, aged 74.

Cretzmeyer, Charles Henry ⊛ Algona, Iowa; S University of Iowa College of Medicine, Iowa C 1901; on the staff of St. Ann Hospital, where he d May 6, aged 78, of a heart attack.

Cummings, Claude Wiggins, Colonel, U. S. Army, tired, San Francisco; Vanderbilt University School Medicine, Nashville, Tenn., 1912; service member the American Medical Association; veteran of Wo War I; entered the medical corps of the U. S. Army 1917; retired Sept. 30, 1944; died in the Lettern Army Hospital May 6, aged 76.

Finady, William Aaron, Bethlehem, Pa.; Medi Chirurgical College of Philadelphia, 1910; membe the Medical Society of the State of Pennsylva fellow of the American College of Surgeons; on staff of St. Luke's Hospital, where he died June aged 69.

Garrison, Amos Rule, Byington, Tenn.; University Louisville (Ky.) Medical Department, 1904; past-pr dent of the Knox County Medical Society; for m years member of the county school board; died in Fort Sanders Presbyterian Hospital, Knoxville, J 26, aged 78.

Hall, Henry Francis, Chicago; Meharry Medical C lege, Nashville, Tenn., 1909; died in the Manteno (State Hospital April 14, aged 80.

Hankins, Frances Cantrall, Alhambra, Calif.; Northwestern University Woman's Medical School, Chicago, 893; died July 6, aged 96, of coronary heart disease.

Harrelson, Rose Cranse Jr., Tabor City, N. C.; Jefferon Medical College of Philadelphia, 1945; veteran of World War II; on the staff of the Loris (S. C.) Community Hospital; accidentally drowned in Myrtle Beach, S. C., June 27, aged 36.

Hatcher, Martin Armstead, Hamlet, N. C.; Medical College of Virginia, Richmond, 1918; member of the Medical Society of the State of North Carolina; past-president of the Richmond County Medical Society; member of the Richmond Selective Service Board; veteran of World War I; on the staff of the Richmond County Memorial Hospital, Rockingham, and the Hamlet Hospital; died June 23, aged 66.

Hennell, Herman ⊕ New York City; Long Island College Hospital, Brooklyn, 1920; member of the American Trudeau Society; served on the faculty of Columbia University College of Physicians and Surgeons; on the staff of the Mount Sinai Hospital; died July 1, aged 68, of coronary disease.

Holtzhausser, George J., Philadelphia; University of the South Medical Department, Sewanee, Tenn., 1899; also a graduate in pharmacy; an associate member of the American Medical Association; died June 30, aged 84.

Hutchinson, James Thomas ⊕ Lubbock, Texas; Tulane University School of Medicine, New Orleans, 1909; veteran of World War I; past-president of the Lubbock-Crosby Counties Medical Society; member of the board of trustees of the Lubbock Independent School District for a 35-year period, 33 of which were spent as board chairman; formerly director of the First National Bank of Lubbock; associated with the Methodist Hospital, where he died June 22, aged 76.

Jellis, Walter, Somerville, Mass.; Tufts College Medical School, Boston, 1920; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the Massachusetts Medical Society; veteran of World War II; died May 12, aged 59, of heart failure.

Kauffmann, Louis John ⊕ Millville, N. J.; Jefferson Medical College of Philadelphia, 1910; on the staff of the Millville Hospital, where he died June 24, aged 68.

Koskela, Albert Leo ⊕ Santa Cruz, Calif.; University of Minnesota Medical School, Minneapolis, 1946; member of the American Academy of General Practice; died July 2, aged 37.

Leary, Maurice Thomas ⊕ Meadville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1917; on the staffs of the Meadville City Hospital and the Spencer Hospital, where he died June 27, aged 61, of heart disease and hypentension.

Leavitt, Harry Clayton, Long Beach, Calif.; Chicago Medical School, 1938; service member of the American Medical Association; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; veteran of World War II; associated with the Veterans Administration Hospital; died May 31, aged 45, of coronary thrombosis.

Leopold, Raymond Sylvester ⊕ Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1906; formerly executive vice-president and trustee, Hahnemann Medical College and Hospital; served on the state board of medical education and licensure; died in the Germantown Hospital June 30, aged 73.

Lesses, Max ⊕ Salem, Mass.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1905; on the staff of the J. B. Thomas Hospital in Peabody; formerly on the staff of the Union Hospital, Lynn; died in the Beth Israel Hospital, Boston, July 4, aged 75, of carcinoma of the pancreas.

Malley, George Calvert ⊕ Zanesville, Ohio; Long Island College of Medicine, Brooklyn, 1930; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; past-president of the Good Samaritan Hospital staff; served as chief of pediatrics at Bethesda Hospital; died June 12, aged 53.

Marks, Julian Barnett ⊕ Los Angeles; University of Illinois College of Medicine, Chicago, 1918; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; died in the Santa Monica (Calif.) Hospital April 5, aged 65, of coronary thrombosis.

Martin, Ruben Ferdinand, San Antonio, Texas; St. Louis University School of Medicine, 1910; veteran of World War I; died in the Veterans Administration Center, Temple, May 21, aged 72.

McFarland, George Edwin ⊕ Los Angeles; University of Minnesota Medical School, Minneapolis, 1942; veteran of World War II; at one time health officer of San Luis Obispo County; on the staff of the California Lutheran Hospital; died in the Centinela Valley Community Hospital, Inglewood, Calif., June 23, aged 45, of seminoma with metastasis.

Meharg, Shelton Theodore, Anniston, Ala.; Memphis (Tenn.) Hospital Medical College, 1900; during World War I served as acting assistant surgeon in the U. S. Public Health Service; served as director of Anniston National Bank; died June 19, aged 78.

Milligan, Edd Fitch ⊕ Geary, Okla.; Denver and Gross College of Medicine, Denver, 1905; veteran of World War I; died June 16, aged 81, of pneumonia.

Moore, Robert W., Memphis, Tenn.; Meharry Medical College, Nashville, 1914; died May 7, aged 71, of cerebral hemorrhage and hypertension.

FOREIGN LETTERS

AUSTRIA

Unusual Case of Pleurisy.—At the meeting of the Vienna Society of Physicians on June 21, A. Sattler reported the case of a 62-year-old physician who had had amebic dysentery in 1941. The patient fell seriously ill in December, 1956, with diarrhea, abdominal pains, and fever. Treatment with antibiotics was without result. The patient was admitted to the hospital where the diagnosis of sigmoiditis and diverticulitis and a hemorrhagic exudative pleurisy on the left was made. Thoracoscopy was requested because the patient's cachexia and the hemorrhagic exudate suggested cancer. The thoracoscopy was performed with difficulty because of the basal sacculation. Finally sufficient space for endoscopy was made by aspirating 300 cc. of exudate and replacing it with air. There was no evidence of pleurocarcinoma but rather of true pleurisy. The most remarkable findings were two cystoid formations of the dorsal part of the lungs, which were inflated at inspiration and retracted in a funnel-shaped form at expiration. A blood clot was observed on top of one of these formations. This finding ruled out a malignant exudation. The cystoid formations were believed to be residues of pulmonary abscesses. The cause of the disease could not be determined by inspection. Because of the patient's history of amebiasis, a parasitologist was called in and he was able to identify trophozoites of Entamoeba histolytica in the pleural fluid and rectal smears.

Chemotherapy of Malignant Tumors.—At the sixth Austrian Cancer Meeting held in Vienna in May, H. J. Wolf and N. Gerlich (Bielefeld) said that they had used ethyleneimine quinone (E-39) in treating 265 patients suffering from all kinds of malignant tumor. Only patients with inoperable tumors or with metastases were included in this series. Since it is important to have the cytostatic drug act on the tumor in a most concentrated form and as long as possible, the drug was injected directly into the tumor. A temporary disappearance of the tumor may thus be obtained and this without the formation of necrosis or abscess. Toxic manifestations are minimal when the drug is used in this way, but if it is given intravenously, not only is proliferation inhibited in the tissue of the tumor but also the formation of leukocytes, erythrocytes, and thrombocytes in the marrow and reproductive cells in the gonads is inhibited, and growth in children may be hindered. It appears, therefore, important to give large doses for a short time and to repeat the treatment at intervals after the restoration of the leukocytes.

E. Bauer (Vienna) said that in using E-39 it is important that this treatment be given at the optimum time. Autointoxication can be prevented by the removal of the already necrotic tumor masses This relieves the pain of tension and produces an improvement of the general condition. The leukocyte count is not a reliable guide to dosage. The bone-marrow inhibitory effect of the drug and the leukocytosis stimulated by the necrotic tumor ac antagonistically. A complete withdrawal of the drug or special therapeutic measures were never necessary, not even in patients with a marked leukopenia. Treatment with E-39 must be given intravenously for a long period (the exact duration is still undetermined), if one does not want to risk a widespread metastasis and an intractable loca recurrence.

A. Bucher (Vienna) said that seven patients with carcinoma of the bladder received local treatmen with the drug and in three others it was injected intravenously. The growth of the tumor appeared to be checked for a while in some patients, and in others the tumor became smaller. While this treatment was being given, tenesmus rapidly subsided and the patients felt better and gained weight.

F. Hesse reported that, for three years in Norderney, treatment with E-39 has been used in patients with cancer. The patients were given 5 mg. daily for several months and in one patient for over two years. In most patients the result was good. No damage to the myelopoietic system occurred, in spite of the prolonged treatment.

J. Kretz said that the toxicity of this drug as well as that of the disintegration products of the tumor should be kept in mind. Intravenous doses of 10 mg. of E-39 three times a week may quickly lead to an inhibition of growth. It is unwise to attempt to obtain a softening of the tumor in the shortest possible time. Impairment of the blood picture makes it imperative to stop intravenous injections and direct injection into the tumor may lead to bleeding or perforation. A rapid disintegration of the tumor may also stimulate its growth. A longer treatment with smaller doses is, therefore, preferable. Sudden withdrawal of the drug may also be disastrous. Capsules for oral use may be given for a slow withdrawal of the drug. Tolerance for and efficiency of this treatment are increased by simultaneous general treatment with vitamins and dietary and medicinal protection of the liver.

P. Wurnig (Vienna) said that since drugs do not cure patients with extensive or advanced carcinoma, they were used as postoperative treatment of carcinomas radically operated on. An efficient but harmless drug that is easy to apply is required. Nitromin, a derivative of nitrogen mustard, was therefore used. The experiment was carried out in selected patients with carcinoma of the bronchi, since these patients have the most rapid downhill course. During the experimental period, all these patients underwent preventive treatment with Nitromin. The treatment consisted of three series of injections, each with a total dose of 700 to 800 mg. administered at intervals of from 6 to 8 weeks. The drug was well tolerated. The results showed that six months after the operation the life expectancy was 20% longer than in the untreated control group; one year later the life expectancy was 10% longer.

Radiotherapy of Tumors.—At the same meeting, A. Kohler (Munich) said that the value of preoperative irradiation of patients with cancer of the breast is now established. Of 459 patients who had preoperative irradiation of carcinoma of the breast in every stage, 41% were still living 10 years later. Delays of operation of one and one-half to five months are therefore allowed. Each daily dose devitalizes or inactivates cells of the carcinoma that are just dividing. Healing of the wound and recovery are normal, since a general but also a local recovery takes place between irradiation and operation. Favorable results with preoperative irradiation of patients with cancer of the breast were also obtained by W. Zaunbauer (Vienna), F. Melnizky (Salzburg), and E. Scherer (Marburg-on-Lahn) who pointed out that the skin condition is better with preoperative irradiation and that local recurrences and pulmonary fibrosis are less frequent. Although Melnizky does not use the usual interval between irradiation and subsequent amputation of the breast, his results are equally satisfactory and healing occurs without complications.

H. Stech said that the body is divided into six fields and every day one field is irradiated with 15 r. Undesirable general reactions and changes in the blood findings are thus reduced to a minimum. Duration and intervals of the irradiation depend on the blood findings and the prothrombin level. The patients are given up to four treatments with a total dose of 720 r at longer and longer intervals for one year. Teleroentgen-ray therapy combined with local inflammatory irradiation is particularly desirable for patients with generalized carcinosis, for patients in poor general condition with inoperable bronchial carcinoma, and, as prophylactic postoperative follow-up, in patients with a special risk of metastasis. In patients in whom recurrence cannot be prevented, prolonged disability associated with pains and increasing cachexia may be avoided by using this treatment in small doses. Death occurs rapidly after there has been a period of relative well-being.

K. Fochem (Vienna) said that carcinomas, stages 1 and 2, of the cervix uteri, as well as the operable carcinoma of the corpus uteri, were operated on and intensively irradiated using two abdominal and two gluteal fields. Inoperable carcinomas, stages 3 and 4, of the uterus were treated with 15,000 r of radium in three treatments. Following radical excision of ovarian and tubal carcinomas, patients are given postoperative x-ray therapy and local applications of radioactive gold. A patient with ovarian carcinoma whose operation was palliative is given one irradiation with 2,400 r. In patients with vulvar carcinoma, operation and irradiation are combined. It is possible to give up to 20,000 r with the filtration method. Massive doses of irradiation are essential, since a recurrent carcinoma after small doses of x-ray is resistant to therapy.

Serum Iron, Copper, and Transferrin Levels in Malignant Diseases.—At the same meeting, E. Gisinger said that in most patients with malignant diseases a decrease of the serum iron and transferrin level and an increase of the serum copper level occur simultaneously. This is particularly true in patients with Hodgkin's disease. If bleeding and, therefore, iron deficiency occurs, an increase of the transferrin level occurs, in spite of the presence of a malignancy, as an unequivocal diagnostic symtom of the iron deficiency. The individual leukosis can be distinguished to a certain degree since in patients with chronic leukemia the iron level in the serum is decreased, in those with the lymphocytic form the serum copper level is increased, and in those with granulocytic leukemia the levels are normal. Acute granulocytic leukemia is characterized by increased levels of copper and iron. Decrease of the transferrin level is found in patients with every form of leukemia. Patients with beta-myeloma have a normal serum copper level, whereas those with gamma-myelomas have an increased serum copper level. In 18 of a series of 23 patients with Hodgkin's disease, good results were obtained by cytostatic treatment. The size of the tumor decreased, the manifestations of Hodgkin's disease subsided, subjective complaints disappeared, and in some there was a complete regression of the inflammatory glands. The serum iron, copper, and transferrin levels returned to normal in three of these patients after treatment. The patients remained without recurrence four or more months. In five other patients, who showed no clinical improvement, the serum iron, copper, and transferrin levels did not return to normal.

Melanoma.—At the same meeting, G. Eichelter (Vienna) said that even a test excision in patients with pigmented nevi and melanoma may lead, under certain circumstances, to metastasis, if malignancy is already present. No pigmented mole should be operated on without prophylactic irradiation. As far as is known r-ray contact irradiation does not produce metastasis. Up to 30,000 r may be applied if necessary. This therapy also gives excellent cosmetic results. Eventually additional irradiation of the regional lymph nodes may be given. If the skin disease is unchanged after the irradiation, excision may be performed more or less extensively under the protection of the previous irradiation with essentially less risk. Further treatment depends on the histological examination.

FINLAND

Deafness.—Siirala and Lahikainen (*Nordisk medicin*, July 4, 1957) examined the employees of a ship-building company, 185 of whom were exposed to loud noise while at work. They were classified in four groups according to the length of their employment. The first group included the workers whose exposure to industrial noise had lasted 10 years or less and the fourth group those whose exposure had lasted more than 30 years. It was found that the detrimental effect of noise continues as long as exposure to it lasts, and the worker does not get accustomed or inured to noise with the passage of time. After a person has been one year in a noisy occupation, his hearing has deteriorated as much as in three normal years. In other words, taking into account that these two types of deterioration of hearing are much alike, it may be claimed that the aging effect on hearing is three times as rapid in noisy as in quiet occupations.

Herpes Zoster Ophthalmicus.—The eye department of Mellersta Hospital, Jyväskylä, serves a population of about 250,000 inhabitants and in the last three years has had occasion to deal with five cases of herpes zoster ophthalmicus. In *Nordisk medicin* for June 13, Dr. A. Oksala points out that the variety of remedies for this disease reflects the want of any specific remedy for it. He has not obtained satisfactory results with salicylates, posterior pituitary injection (Pituitrin), or ergotamine tartrate, and he has found that the value of antibiotics depends only on the elimination of secondary infections. Cortisone and hydrocortisone have been used only locally, and the effects have been satisfactory. The combination of cortisone with mydriatics is an improvement on earlier methods. Good results have also been obtained with injections of a liver extract with the cessation of pain and fever occurring in 24 hours. Should a second injection fail to achieve this effect, the treatment should be discontinued. Such injections apparently promote healing of the skin eruption and prevent postherpetic neuralgia.

Postural Hypotensive Collapse Caused by Chlorpromazine.—Stenbäck and co-workers (*Nordisk medicin*, May 16, 1957) studied the effects of chlorpromazine on 28 patients with special reference to the development of postural hypotensive collapse. They were subjected to Schellong's test which provides for measurements of blood pressure when the patient is in bed, standing up, and lying down. It was found that orthostatic hypotensive reactions to chlorpromazine given by injection four times daily take place mainly within the first 48 hours, but such reactions may occur even after 10 to 13 days. It was hoped that these examinations would give a clue to the likelihood of postural hypotensive collapse in a given case before chlorpromazine treatment was instituted. The need for such a prognostic clue is great because such collapse may prove fatal.

PERU

Institute of Biochemistry.—On March 23 the Institute of Biochemistry of the Faculty of Medicine of Lima was dedicated. Albert Baird Hastings, professor of biochemistry of the Harvard University Medical School, and representatives of the Kellogg and the Rockefelle foundations, two institutions that have contribute technical and financial assistance, attended the ceremony. Prof. Alberto Guzmán Barron has been name director of this institute.

Council on Mental Health.—In March the Ministry Public Health created the Council of Mental Healt with Sebastián Lorente as president. Juvenile deli quency, a growing problem in Peru, will be studie intensively. Other pressing problems are the provisio of more mental hospitals and the increasing of th availability of outpatient psychiatric services.

Mobile Medical Units.—Three mobile medical uni have been purchased by the National Fund of Healt and Social Welfare for about $40,000 each. They wi be principally used for mass x-ray examination of th lungs, but they can also give minor medical, surgica and dental care. Most of their work is being carrie out in the poor suburbs of Lima.

Infectious Mononucleosis.—Dr. Castro Hoyos reporte on 15 patients with infectious mononucleosis, 11 whom were treated with prednisone or prednisolo (*Revista médica del Hospital Obrero*, vol. 5, no. 3- Dec., 1956). The age of the patients ranged from 2 14 years. The most prominent manifestations we fever, cervical or generalized adenopathy, sore throa bronchitis, and rash, in that order. In the 11 patien treated with hormones, dramatic and prompt relief symptoms was noted, the fever disappeared within to 8 hours of starting the therapy, the general malais and sore throat subsided completely, the hypertrophie lymph nodes became smaller, and pain and tenderne diminished or disappeared. The author called attention, however, to the absence of significant hematological changes after hormonal therapy. Furthermore when given early, both hormones failed to prevent the ppearance of the adenopathy and the rash. Cough was ot affected by the hormones. The theoretical ground or the use of these steroids in the treatment of infec- ious mononucleosis is the well-known lympholytic ffect accounted for by their glycocorticoid activity. The initial dose was 10 mg. four times daily. This was educed slowly until a daily maintenance dose of 5 ng. was reached by the 14th or 15th day.

Medical Women's Association.—The first Latin-Amer- can medical women's association has been organized n Peru. The installation ceremony took place on July 8 at the Faculty of Medicine of Lima and was attended by the president of the nation, Manuel Prado, the minister of public health, and many prominent physi- ians. The membership of the organization is about 00, and its president is Dr. Suzy Roedenbeck, auxili- ary professor of neuropathology at the Faculty of Medicine, San Marcos University. The purpose of the association will be to encourage and protect the medi- cal interests of the Peruvian woman.

Chlorpromazine and Chronic Psychoses.—Dr. Querol and co-workers (*Revista de neuro-psiquiatría*, vol. 19, no. 4, Dec., 1956) reported on the treatment of 26 pa- ients with chronic schizophrenia and 6 with chronic nanic-depressive psychosis with chlorpromazine. Most previous reports on the value of this drug in mental conditions have shown the following: 1. It has a tran- quilizing and sedative action on the patient's psycho- notor agitation regardless of the origin of the agita- ion. 2. In the confusional states it reduces both the confusion and the delirium, and patients become well oriented and attentive. 3. It causes hallucinations to disappear. 4. In depressed states it causes the anxiety, feelings of indignation, and suicidal impulses to dis- appear. 5. In many patients with schizophrenia unre- sponsive to conventional treatment it causes either mprovement or a social or complete remission of the disease. 6. Withdrawal of the drug is frequently fol- lowed by relapse, but good response is again obtained shortly after the therapy is resumed. The patients in the authors' series underwent chlorpromazine treat- nent alone or in combination with electroshock thera- py and sedative medication. All patients received from 100 to 600 mg. of chlorpromazine daily long enough to modify their symptoms or for at least three months. Twenty-two of the schizophrenic and all of the manic- depressive patients had suffered from the disease more than one year. The remaining four schizophrenic pa- tients had been ill from 6 to 12 months. In all the pa- tients other previous treatment had failed. In the schizophrenic group, six patients were improved and four gained social remission and seven complete re- nission. Of the rest, eight were unchanged and one died. Four complete remissions and two deaths were observed in the manic-depressive group. None of the patients who died showed any benefit from the treatment, but no death could be directly attributed to the drug.

Catatonic and paranoid schizophrenia responded better to the treatment than did the simple and the hebephrenic types, and, in general, the results tended to be better in patients whose disease was of short duration. Recurrences of the symptoms occurred in three patients, but resumption of the treatment brought about prompt improvement. The authors believe that in refractory cases it is advisable to give the drug for as long as six months. Parkinsonism was the most frequent untoward side-effect observed in the patients treated with chlorpromazine. It was noted in 13 of the schizophrenic group and disappeared when the dose was diminished. In only a few patients was it necessary to discontinue the treatment temporarily. Obstinate constipation was another frequent secondary effect. Neither hepatic nor dermal complications were noted. Bronze pigmentation of the face was observed in seven patients. This side-effect, not reported before, cleared up slowly after the treatment was finished. The authors concluded that chlorpromazine must be regarded as the drug of choice for patients with endogenous psychoses, even though chronic. On the other hand, they pointed out that the psychological modifications produced by chlorpromazine do not equal those elicited by leukotomy.

Sanatorium for Tuberculous Children.—Peru's one and only tuberculosis sanatorium for children under 14 years of age was opened in 1950. Because its capacity was small (100 beds), most tuberculous children still had to be treated in a general hospital, with the consequent overcrowding of the children's wards in the latter. In March a 200-bed addition to the sanatorium was started. The new building will also include additional x-ray and laboratory equipment and a new electric-power plant.

UNITED KINGDOM

Annual Cancer Review.—The two main features of the annual report of the British Empire Cancer Campaign for 1956 are the increasing amount of work being carried out on the association between smoking and lung cancer and the rapid extension of the clinical uses of isotopes. Professor R. D. Passey and co-workers have failed, in spite of persisting efforts, to demonstrate any carcinogenic properties in the tar from cigarettes when applied to the skin of mice. A group of rats has been injected subcutaneously with English cigarette tar, and several series of hamsters have had a similar tar instilled into the trachea. In no instance in either species has any tumor arisen as a result. In further experiments in which groups of hamsters were exposed to the smoke of cigarettes for long periods daily in smoking machines some of the animals survived for 20 months without any evidence of lung or other cancer. Although tracheitis, bronchitis, and bronchiectasis have been observed in rats subjected to the same condition, no tumors have arisen.

In other experiments, three groups of rats have been exposed, over a period of 10 months, to atmospheres containing cigarette and coal smoke and to a combination of the two. In none of these animals has any sign of neoplastic change occurred. The lyophilic, lyophobe, and phenolic fractions of tobacco tars have been painted on the interscapular region of 250 mice, and a crude tobacco tar has also been injected subcutaneously in 50 mice. Although the tests have been in progress for 21 months, no tumors have developed in either the painted or injected series. Professor Passey says: "During the last three years all those in Great Britain working on the effects of exposure to cigarette smoke or its tars have been consistent in reporting complete failure to demonstrate any carcinogenic action in a variety of laboratory animals, in spite of the proved presence of traces of the carcinogenic hydrocarbons in cigarette tars. This is in marked contrast to the reports from Wynder and his co-workers in America (1953, 1955). The difference in these results must be in the tars."

E. Boyland and D. C. Williams have continued their investigations of urinary beta-glucuronidase. Patients with cancer of the stomach, esophagus, rectum, breast, testis, and prostate have a higher than normal urinary beta-glucuronidase level, but those with cancer of the colon, thyroid, and kidney excrete normal amounts. A greatly increased urinary beta-glucuronidase activity is exhibited by patients with leukemia, Hodgkin's disease, cancer of the bronchus and prostate, and various types of cancer of the bladder (including those who have had their tumors removed and at the time of investigation have no active tumor). Prolonged treatment of patients with cancer of the prostate with diethylstilbestrol causes a great increase in beta-glucuronidase excretion. Since some nonmalignant diseases such as gastric ulcer, bronchitis, and coronary thrombosis also cause increase in beta-glucuronidase activity, the use of such activity as a diagnostic test for cancer is impracticable. Some evidence of therapeutic effect was obtained from the use of 2-chloro-ethyl methane sulfonate in 3 of 22 patients with terminal malignant disease. Forty-seven patients were treated with NN-di-(2-chloroethyl)-*p*-amino-L-phenyl alanine. In general, clinical results were disappointing, but there was recent evidence that intravenous administration may be much more effective. Three patients with chronic granulocytic leukemia have been treated with dimethyl busulfan. All have responded and are in remission.

The physics department of the Institute of Cancer Research reports the installation of the first British cesium unit, which was loaded in October with about 1,400 curies of cesium sulfate encapsulated in platinum. Preliminary studies were also made for a small cesium-137 unit suitable for treating lesions of the head and neck. It is apparent that, for this purpose, cesium-137 has several advantages over x-rays, radium, or cobalt-60. Yttrium-90 was used for radiation hypophysectomy, particularly in patients with mammary carcinoma. Two or three rods, 1.3 mm. in diameter and 4 mm. long, made of sintered yttrium oxide, each of activity of about 3 mc., are introduced into the pituitary under image amplifier control. Improved eye applicators of strontium-90 and yttrium-90 have been developed. These are satisfactory in clinical use, are durable, and have no constituents which may break down under irradiation. Work has continued on the applications in clinical radiography of low energy gamma-emitting isotopes, particularly radioactive xenon-133. Using high activity xenon sources, good radiographs of fractures of the wrist and ankle have been obtained with exposures of a few seconds. A technique of scintillation counting of alpha particles was developed for the measurement of low alpha activities in solid, liquid, or gaseous samples. This technique is proving remarkably simple, flexible, and consistent and is being used to estimate alpha activity in bones of persons who have lived in various environments and who have been exposed to special types of occupational hazard and in a variety of foodstuffs, soils, artificial fertilizers, and pharmaceutical substances.

New apparatus was designed and built for the intravesical administration of radioactive colloidal gold for the treatment of patients with multiple superficial papillary tumors of the bladder. A surface dose to the mucosa of 7,000 to 8,000 r (90% irradiation) is delivered over a period of 6 to 12 weeks in three separate treatment sessions lasting about three weeks each. In only a small proportion of patients so treated is the bladder rendered completely tumor free; in the remainder the tumor regression is usually of such an order that the small residual lesions can readily be treated by periurethral diathermy. Eighty patients with polycythemia were treated with phosphorus-32, the dose per injection ranging from 3 to 12 mc. The largest amount given to one patient was 47 mc. Ten of these patients died—five from intercurrent disease and five with leukemia or polycythemia present. In a program of research into calcium metabolism in malignant and nonmalignant bone disease, three patients have been studied so far. In one, radiostrontium was injected with the radiocalcium, and it was found that the 48-hour urinary excretion of strontium was five times as great as that of calcium.

At the Middlesex Hospital, 70 patients with cutaneous carcinoma induced by ionizing irradiations were studied. There were almost equal numbers of squamous and basal carcinomas which had arisen in patients previously treated by radiotherapy or exposed occupationally to ionizing irradiations. The most common disease so treated was lupus vulgaris, in which squamous cell tumors were found more often than rodent ulcers when malignant disease ensued. There were only 4 patients in whom squamous cell carcinoma developed in lesions of lupus vulgaris as compared to 16 in whom radiotherapy had been used in treating the lupus. Rodent ulcers were seldom seen after irradiation of lupus vulgaris lesions but appeared after depilation for ringworm of the scalp, sycosis barbae, or hypertrichosis of the face. In addition, four patients who were successfully treated by surgery and radiotherapy for mammary cancer developed rodent ulcers in areas of roentgen-ray dermatitis over the chest.

At St. Bartholomew's Hospital, intrapulmonary inoculations of known carcinogens and tobacco tar were made into the lungs of white rats, the material being injected directly around the root of the lung after the thorax had been opened. After methylcholanthrene had been injected, sarcoma occurred in 12 of 15 rats and after benzpyrene had been injected, sarcoma developed in 10 of 17, and in one an epidermoid carcinoma developed. In the series injected with methylcholanthrene, the average time between the inoculation and the death of the animals was 257 days, and in the series injected with benzpyrene, the time interval was 254 days. The same technique was used in investigating tobacco tar from a smoking machine and from a proprietary cartridge type of filter on sale in this country and believed to contain granules of silica-gel. About 10 cigarettes per filter were smoked by human subjects, the filters thereafter being washed out with acetone. Smoking-machine tar produced no tumors in a series of 10 rats, though the average time the rats lived was 464 days. Tar from the filters was injected into the lungs of eight rats; it produced one spindle-cell sarcoma in a rat that lived 607 days and one oat-cell cancer in a rat that lived 506 days.

Analyses of 39 brands of cigarettes from Austria, Bulgaria, Canada, Denmark, England, Finland, France, Germany, Greece, Italy, Norway, Poland, Rhodesia, Spain, Switzerland, United States, and Yugoslavia show that, as one passes eastwards in Europe, there is a fairly uniform decrease in the arsenic content of a cigarette weighing about 1 Gm. from as much as 100 mcg. to 1 mcg. or none. This is almost certainly due to the admixture of decreasing amounts of tobacco from the United States with increasing amounts of locally grown tobacco classed as "Turkish." Analysis of one of the most popular brands smoked in this country shows a fall in arsenic content from between 25 and 100 mcg. per cigarette in 1948-1949 to between 1 and 2 mcg. at present. This change appears to be due to the gradual abandonment of arsenical insecticidal sprays by tobacco growers in the United States.

At the Westminster Hospital, high-dosage pituitary seeding with gold radon seeds has been given up because of the poor results (average postoperative survival 3 months) and the number and severity of complications attending the procedure. As an adjunct to surgical hypophysectomy, however, radon seeds are left in the pituitary fossa. Sodium liothyronine combined with neomycin has been used, with encouraging results, as a local application in five patients with radiation necrosis. A new method of investigating the colloidal properties of urine has been evolved to study the protective action of such colloids. Preliminary results indicate that high concentrations of albumin or of mucoprotein are always associated with a high protective activity. This has been noted particularly in urines from patients with various malignant conditions, some of which have high mucoprotein levels. At lower mucoprotein levels, however, no correlation was present, and some pathological urines with normal protein and mucoprotein levels had a protective activity much above normal. The Marie Curie Hospital reported a 10-year follow-up of cancer of the cervix and of the body of the uterus treated by radium or a combination of radium and x-rays. Of 1.829 patients with cancer of the cervix, the 10-year survival rate was 30.2% of the patients treated, ranging from 69.7% for those in stage 1 to 4.4% for those in stage 4. The corresponding figures for the 308 patients with cancer of the body of the uterus were 36.4%, ranging from 86.4% to 13.4%. The records of this hospital showed that carcinoma of the vagina is a disease of later life, the greatest incidence being in the seventh and eighth decades. Thus, of the 79 patients treated in the hospital, 32 were in the seventh decade and 25 in the eighth decade.

St. Mark's Hospital reported that in a series of 4,500 patients with cancer of the rectum and colon, the operability rate was 75.6%, but in the first five years (1928-1932) it was 47.7% and reached 93% in the years 1953-1955. This steady increase in the proportion of patients operated on was attributed to the growing conviction that surgery not only prolongs life but also improves it. In a series of 120 colectomies undertaken for the treatment of ulcerative colitis, unsuspected cancer was found in seven cases, an incidence of 5.8%. A study of the relationship of carcinoma of the rectum and pregnancy indicated that pregnancy does not adversely affect the course of carcinoma of the rectum and that there is no indication for therapeutic abortion except when infection is anticipated and in some inoperable cases. Patients with carcinoma of the rectum diagnosed during pregnancy should be treated in the same way as those who are not pregnant, except that, when the diagnosis is made in the last two months of pregnancy, operative treatment must be delayed until after delivery, which may be performed before term by cesarean section.

At the Hospital for Sick Children, 28 patients with histologically verified neuroblastoma were treated with vitamin B_{12}, the dosage in most cases consisting of 1 mg. given intramuscularly on alternate days for a period of two years when possible. Most of these children were selected for this treatment because no other mode of therapy offered any prospect of arresting the disease. Of these 28 children, 13 died without showing any significant response. The rest all showed definite evidence of tumor arrest or regression. In nine patients this was maintained for periods of from seven months to six years from the inception of treatment and all nine were alive when last seen. The observation of regressive phenomena in 50% of the patients treated in this series is greatly in excess of that occurring spontaneously (probably 1 to 3%). Regression was observed only in those with a clinical onset in infancy. There were only two instances of remission in the older age-group, despite the fact that the latter represented 50% of the total series.

P. M. F. Bishop is investigating the alleged carcinogenic effect of prolonged administration of estrogens by following up a series of 840 patients who, between 1937 and 1953, had a minimum of six months' treatment with estrogen. Of the 420 patients so far traced, only one had adenocarcinoma of the uterine body, and one had carcinoma of the breast. Ten women have died, and in none of these was there either a mammary or genital carcinoma. A further 220 patients with a definite history of metropathy or menorrhagia, i. e., patients with an excessive amount of endogenous estrogen, are being studied. Of the 120 so far traced, 38 (30%) have undergone hysterectomy; 8 showed definite evidence of cystic glandular hyperplasia; and 8 showed some evidence of hyperplasia. None had any evidence of malignancy. Another approach to the problem was through a study of 88 unselected patients with carcinoma of the uterine body. Only three of these had received estrogen therapy for more than a year preceding the diagnosis of malignancy.

Preliminary results of investigations into the smoking habits of women with lung cancer living in urban and rural areas of North Wales, Cheshire, and Lancashire, according to Percy Stocks, support the previous findings for men that both smoking and urbanization are independently related to lung cancer mortality.

A report on the conference on estrogen methodology, organized by the British Empire Cancer Campaign, stresses that any satisfactory quantitative estrogen methods must be very complex and technically difficult and that therefore they should not be lightly undertaken with inadequate facilities. The two currently used methods critically examined at the conference are unsuitable for routine use in a hospital laboratory. They were designed for use in specially equipped and staffed laboratories, as the precision and accuracy of which they are capable can only be attained under these conditions. The publication of results obtained by any method for the determination of urinary estrogens by workers who have not themselves determined the precision and accuracy of that method is to be deplored.

Family Physicians Feel Let Down by Some Consultants.—Sir Russell Brain, past-president of the Royal College of Physicians and one of the joint chairmen of the doctors' negotiating committee, in the recent claim for a 24% pay increase, was criticized at the British Medical Association's annual meeting at Newcastle-upon-Tyne. A split in the profession was feared. Many family physicians believed that, in their dispute with the government, they had been let down by some of the specialists of Harley street. The charge against Sir Russell was that he had indicated that, in the event of pay talks with the government breaking down, the decision as to the action to be taken would not be made by the B. M. A. alone. In conversation afterwards, many physicians deplored the attack on Sir Russell. The B. M. A. maintains that the Spens reports place a moral obligation on the government to increase doctors' pay as the cost of living rises. The government rejects this interpretation. A motion by Dr. H. G. Dowler asked that, as moral obligations had evidently ceased to be obligatory, in future only terms of service in the National Health Service enforceable in law should be accepted. Dr. Solomon Wand, chairman of the B. M. A. council and a principal negotiator in the dispute with the government over pay, said that the government had indicated that the physicians' claim could not be considered on its merits because it would have such inflationary results. This might have seemed a fair assumption had not the members of Parliament a few days later voted themselves a substantial raise. Dr. C. P. Wallace proposed the resolution which led to the attacks on Sir Russell Brain. He moved that it was improper for any individual member of a joint negotiating committee to take independent action without the prior consent of the whole committee. There were cries of "Why?" when Dr. Wand described Dr. Wallace's speech as unfortunate. "Because," he replied, "we are not recriminating on the past; we are looking to the future." A motion to pass to the next business was defeated. Dr. G. Cormack said, "If Dr. Wallace's speech was construed as an attack, that was all to the good. I hope you will pass this as a vote of censure on the man concerned and as a warning to other people who might be of the same mind in the future." The motion was carried.

CORRESPONDENCE

HEALTH IN THE HEAVENS

To the Editor:—Physicians and their scientific colleagues in aviation medicine will be gratified by the intelligent and stimulating review of the current status of space travel, "Health in the Heavens" (*J. A. M. A.* 164:765-769 [June 15] 1957), and by the accompanying editorial in the same issue. To paraphrase the statement of Dr. John F. Fulton in the foreword of "Doctors in the Sky" (Charles C Thomas, Publisher, 1955), the future of the specialty of aviation medicine today appears as boundless as the skies its practitioners are exploring.

A minor error was noted in this excellent article. Dr. John Jeffries accompanied Jean Pierre Blanchard in the first balloon flight across the English Channel on Jan. 7, 1785, not 1795. Earlier, on Nov. 30, 1784, he made an ascension over London. Also, Dr. John P. Stapp recently was given a well-deserved promotion to colonel in the Air Force Medical Corps.

Few physicians will read "Health in the Heavens" without a feeling of pride in the part their profession is contributing to space travel. Likewise, few will doubt that space flight will soon be here—and probably to stay.

MOUNTAIN CLIMBING

To the Editor:—The Leisure Corner article on mountain climbing in the Aug. 3 issue of The Journal, page 1609, was interesting. If it was intended as an introduction, it is probably adequate for eastern mountains but not for western. For fear real mountaineers are out climbing or are too modest to offer suggestions, may an amateur warn beginners about two items of equipment? Climbing in the Rockies above the timberline consists in rock work, and leather-soled shoes are too slippery. Rubber, composition, or similar materials cling to rock and are much safer. Probably most who go onto snow and ice use crampons (removable iron spikes) rather than cleated or nailed soles. Rope work should not be undertaken by beginners without adequate demonstration and instruction. Many prefer the new nylon rope, as it is lighter, stronger, more elastic, and more pliable when wet than hemp. The best way to start is to join a mountain club for a prolonged outing for a week end or longer. The Alpine Club in New York City will gladly furnish information on the closest club or on one in the vicinity of the proposed climbing area.

Colorado mountaineers are probably chagrined to have Montana and Wyoming credited with scores of peaks between 10,000 and 13,000 ft. and Colorado with only Pike's Peak, which has a car road to the top, when, according to the Encyclopædia Britannica, Colorado has "52 of the 67 highest mountains in U. S., all over 14,000 feet." They would prefer mention of their highest peak, Mount Elbert (14,431 ft.) or the peak probably most climbed on foot, Long's Peak (14,225 ft.) and its noted and notorious East Face, 1,625 vertical feet, which is beyond amateur mountain hiking.

PAIN AND PLACEBOS

To the Editor:—In a paper entitled "Codeine Phosphate, Propoxyphene Hydrochloride, and Placebo" published in the June 29, 1957, issue of The Journal, page 966, Gruber refers to some work published by my colleagues and me in 1954 (*Am. J. Med.* 16:770 [June]). Gruber implies that we observed some sort of diminishing efficacy with morphine and with placebo over a period of time. He states that we saw "increasing pain" when placebos were given. I have observed no diminution in the effect of the placebo doses with the passage of time in any studies in which I have participated; on the contrary, placebo and morphine each seem to perform better toward the end of the period of postoperative pain than in the beginning of this period. What we did observe was a definite correlation between duration of pain, severity of pain, and efficacy of morphine or placebo.

HABIT-FORMING DRUGS

To the Editor:—In Foreign Letters in the July 13 issue of The Journal, page 1268, is a short note from France reporting on the effects of a new analgesic 2,2-diphenyl-3-methyl-4-morpholine-butyryl-pyrrolidine (R 875), prepared by P. Janssen of Belgium. The note says, "It is not habit-forming." This product has been studied in the United States, including tests at the Addiction Research Center at Lexington, Ky., with the conclusion that it "has addiction liability at least equivalent to that of morphine (Addendum to the Minutes of the 18th Meeting of the Committee on Drug Addiction and Narcotics of the National Research Council). R 875 was placed provisionally under international narcotics control by the Commission on Narcotic Drugs of the United Nations at its 12th session, and coverage of R 875 under the U. S. Opiates Act has been recommended.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Governmental Hospitals: Liability for Negligence of Employees.—This was an action for damages against a county hospital and its trustees and superintendent for injuries to a pay patient allegedly caused by the negligence of a hospital employee. From a judgment in favor of the hospital the plaintiff appealed to the Supreme Court of Iowa.

Is a county hospital liable for injuries to a patient caused by the negligence of a hospital employee? Under the ancient common law, said the court, the sovereign, generally speaking, could not be sued and this policy is now found in the Iowa statutes. The state is thus immune from suit. Counties, however, are creatures of legislative enactment and may sue and be sued. They are not, as a rule, held liable for torts committed by them, so long as they are acting within the scope of their governmental powers. The difference between a governmental and a proprietary function is that in its governmental function the county is made, by the state, one of its instruments, or the local depository of certain limited or prescribed political powers, to be exercised for the public good on behalf of the state, rather than for itself; while in its proprietary function the theory is that the powers are supposed not to be conferred, chiefly or primarily, from considerations connected with the government of the state at large, but for the private advantage of compact community, which is incorporated as a distinct legal personality or corporate individual.

The defendant hospital was established under Chapter 347 of the Iowa Code. Neither that chapter nor any other statutory provision, said the supreme court, requires a county to provide facilities to care for the sick or infirm, whether indigent or not indigent. Whether or not there shall be a county hospital rests entirely with the county's residents and any assumption of such power is purely voluntary. Under Chapter 347, continued the court, the powers thus assumed are clearly intended, at least primarily, for the private advantage and benefit of the locality and its inhabitants. The majority view is that the operation of a hospital under such circumstances is a governmental function which grants immunity but the tendency is to deny immunity where injury results from negligence of officials or agents exercising purely ministerial powers. The operation of a hospital by a county under Chapter 347 is a proprietary function, at least so far as a pay patient is concerned, said the court, and should be considered in the same light as a private hospital, which, according to well settled law in this state, is liable in tort for injuries to pay patients injured through the negligence of their employees. The motion to dismiss rested on the contention that defendants were merely agents of the county and performing a governmental function, and were, therefore, entitled to the same immunity as the county. Since the court concluded that the county has no immunity, its agents, necessarily, have no immunity either. The judgment of the lower court in favor of the hospital was accordingly reversed and the cause remanded. *Wittmer v. Letts, 80 N. W. (2d) 561 (Iowa, 1957).*

Malpractice: Need for Consent Prior to Plastic Surgery—Minors.—The plaintiff filed a suit for damages for malpractice and assault and battery against the defendant physician for performing a plastic operation on her nose without her consent. From an adverse judgment the plaintiff appealed to the Supreme Court of Ohio.

This appeal concerned only the assault and battery count, the malpractice count having been dismissed by the trial court. The primary issue was whether or not a minor can sue in an assault and battery charge fo an operation to which her parents or guardian did no consent.

The plaintiff, 18 years old but a minor under Ohi law, sought out the defendant physician in respons to an ad in the telephone directory, "Reshape Yo Nose in Plastic Surgery." After an interview and exar ination the defendant physician operated upon t plaintiff's nose. The defendant physician testified th at the time of the operation the plaintiff told him th she was 21 years old and that she called at his offi on several occasions for follow-up treatments. Sub quently, however, she filed suit against the defend claiming that, as a result of the assault and violati of her bodily integrity, permanent changes in the tiss and structure of her nose were made with a detrim tal effect upon her physical appearance, and that was caused to suffer mental shock, humiliation, dep sion, and a general personality and nervous breakdo so that she could not return to her employment.

The term "consent," said the Supreme Court Ohio, as used herein carries with it the assumpt that previous full disclosure of the implications a probable consequences of the proposed conduct which such consent applies has been given in s terms as may be fully comprehended by the per giving the consent. Continuing, the court said that general rule seems to be that, unless there exists emergency, which prevents any delay, or other ceptional circumstances, a surgeon who performs operation upon a minor without the consent of parents or guardian is guilty of a trespass and batt This rule is not based upon the capacity of a min consent, so far as he is personally concerned, wi the field of the law of torts or law of crimes, b based upon the right of parents whose liability support and maintenance of their child may be gr increased by an unfavorable result from the opera al procedures upon the part of a surgeon. The further pointed out, however, that in the present the plaintiff was only entitled to recover nominal ages. It therefore reversed the judgment in favor o plaintiff because more than nominal damages had been awarded by the trial jury. *Lacey v. Laird, 139 N. E. (2) 25 (Ohio, 1956).*

Insanity: Privileged Character of Physician's Testimony.—This was an action against the defendant physician for damages suffered as a result of a detention, following emergency detention proceedings, in a state hospital on the basis of the defendant's allegedly erroneous certificate. From a judgment in the trial court overruling his demurrer, the defendant appealed to the Supreme Judicial Court of Maine.

According to the law in Maine, said the Supreme Judicial Court, municipal officers are authorized to issue immediate restraint and detention orders when such is necessary for the person's comfort or safety or the safety of others providing the complaint is accompanied by physicians' certificate. An examination and certificate of insanity by two reputable physicians is, under the law, a mandatory requirement. Continuing, the court said that, construing the statute as a whole, the certifying physician is a witness in emergency restraint and detention proceedings and the municipal officers are judges. A witness in a judicial proceeding, said the court, is absolutely privileged to publish false and defamatory matter about another as a part of a judicial proceeding in which he is testifying if the defamatory matter is relevant to the subject or inquiry. Therefore, the court concluded, the certificate of the defendant was privileged and his demurrer to the complaint should have been sustained. The judgment of the lower court was accordingly reversed. *Dunbar v. Greenlaw, 128 A. (2d) 218 (Maine, 1956).*

County Hospital: Liability of County for Negligence of Hospital Employee.—This was an action for damages against the county, the county commissioners, and an employee of a hospital established by the county allegedly due to the negligence of the employee. From a judgment for the defendants, the plaintiff appealed to the Supreme Court of Nevada.

The hospital in which the injury occurred was established by the county pursuant to the laws of Nevada and, in a prior suit, it was held that a hospital established pursuant to such laws is not a legal entity and is, therefore, not subject to suit. However, said the Supreme Court, it does not follow from the fact that the hospital is without independent legal entity that there is no public responsibility for torts committed by its employees. The hospital is an institution established, owned, and supported by the county. Having no entity apart from the county, it must follow that the county is the party legally responsible for obligations of the hospital. The county contended that this could not be true in this case because, by statute, the control of the hospital is vested in the trustees elected by the voters of the county and the county commissioners have no management powers. The court said that the fact that the county commissioners are without managerial control does not deprive the county of representation or control or relieve it of liability. The hospital trustees are officers of the county, representative of the county, and responsible to it within their limited sphere of authority to the same extent as are the county commissioners within their general sphere. A county may operate through such agencies as the legislature directs. Accordingly, the judgment in favor of the defendants was reversed and the cause remanded. *Hughey v. Washoe County, 306 P. (2d) 1115 (Nev., 1957).*

Dead Bodies: Who May Authorize Autopsy?—This was an application by the sisters of a decedent for an order authorizing an autopsy on his body for the purpose of determining the cause of death. The decedent's widow filed a motion to dismiss the application, which motion was granted, and the applicants therefore appealed to the Supreme Court of Oklahoma.

The Oklahoma statutes provide: "The right to dissect the dead body of a human being exists . . . whenever any husband or next of kin of a deceased person, being charged by law with the duty of burial, authorized such dissection for the purpose of ascertaining the cause of death." The statute relating to the duty of burying the body of a deceased person specifically provides for those instances in which a married woman dies by placing the duty of burial on the husband or, in the event of his prior death, on the nearest kin. If the deceased is not a married woman, the statute places the duty of burial on the nearest kin, with no mention of a surviving widow. The applicants, therefore, contended that their rights superseded those of the surviving widow since they are the nearest kin.

The Supreme Court said that, as between the wife and other relatives, the great weight of authority is that the care and custody of the body and the right to provide burial rests, in the first instance, with the surviving spouse. The applicants argued that, if the legislature had intended to include the wife, the word "spouse" instead of "husband" would have been used in the law. They argued that the language of the law must be strictly construed, thus depriving a surviving wife of any right or voice in the disposition of the remains of her deceased husband. This, said the Supreme Court, is tantamount to saying that it was intended by the act to make the duty of burial of a deceased person that of a stranger, to the exclusion of a surviving wife, since the law which makes no mention of any surviving spouse, except the "husband," goes so far as to provide that the duty of burial develops upon the tenant, or, if there be no tenant, upon the owner of the premises where death occurs or the body is found. The court held that it was unable to conceive that the legislature, by either reason or necessity, intended any such result. Continuing, it said that courts will not follow the letter of a statute where the literal meaning would lead to absurd consequences which the legislature could not have contemplated. They are bound to presume that such consequences were not intended and to adopt a construction which will promote the ends of justice and avoid the absurdity. The terms "kindred" and "next of kin" as used in the law include a relationship existing by reason of marriage. The applicants, therefore, did not have the primary right of burial over the surviving widow. The judgment of the lower court dismissing the application of the decedent's sisters was accordingly affirmed. *In re Kyle's Autopsy, 309 P. (2d) 1070 (Okla., 1957).*

Charitable Hospitals: Termination of Staff Privileges.—The plaintiff, a physician, filed an action against the defendant, a nonstock hospital corporation, for a declaration that his dismissal from the hospital staff was of no effect, and asking that the trustees be enjoined from depriving him of his rights as a member of the medical staff. From a judgment for the hospital, the plaintiff physician appealed to the court of appeals of Maryland.

By way of background, the evidence showed that the plaintiff and his brother, in addition to practicing medicine, carried on an active real estate business. In 1938, they purchased property which they used as their offices and a small hospital. In 1941, the plaintiff and some associates incorporated Doctors Hospital, Inc., as a nonstock corporation. From 1938 to 1947, the plaintiff's family financed the hospital and made up its board of trustees and the hospital was managed by the plaintiff exclusively. In 1944, Doctors Hospital, Inc., bought property which it intended to convert into a hospital. Because outside capital could not be attracted to a nonprofit corporation, the plaintiff formed Doctors Hospital of Maryland, Inc., a stock corporation. The money from the sale to the plaintiff, his brother, and three other physicians of the stock of this corporation and the proceeds of a mortgage were used to build the present hospital. Operations were begun in the new building in 1947 with the plaintiff personally in control of all operations. When the hospital tried to gain membership in the Maryland Hospital Association, commonly known as Blue Cross, it was learned that this could not be done if the hospital was operated by those who controlled it financially. Doctors Hospital of Maryland, Inc., therefore transferred all its assets to Doctors Hospital, Inc., and was thereafter dissolved. The plaintiff testified that, as part of this transfer, Doctors Hospital, Inc., assumed all obligations of the stock corporation and that he and another physician were given permanent rights to be members of the hospital and its staff. In 1948, a mortgage was executed from Doctors Hospital, Inc., to the plaintiff and his wife on which there is now $100,000 owing. When the hospital sought accreditation from the Baltimore City Medical Society, acting as agent for the American Medical Association, it was told its board of trustees was too small and should be expanded to 15 members, with backgrounds of public service and with no previous business affiliations with the hospital or its staff. The plaintiff, his brother, and two others resigned from the board and new members were elected to take their places. The plaintiff was appointed administrator of the hospital and continued in that position until 1951, when he resigned pursuant to the recommendation of the Baltimore City Medical Society that he do so on the ground that he should not be the executive officer of the hospital while he was on its staff and while it was heavily obligated to him financially. From 1951 on there was friction between the plaintiff and the board of trustees which culminated in the board's refusal to renew the plaintiff's staff privileges.

The plaintiff contended, among other things, that his dismissal was invalid because it was without notice to him and he had no opportunity to be heard. This was based, said the court of appeals, on the contention that he was dismissed for cause, and that in such case the bylaws of the medical staff required notice and hearing. We think this misconceives what occurred, said the court. The plaintiff challenges the validity of the pertinent bylaws of the medical staff adopted by the board in November, 1954, but both before and after November, 1954, the bylaws of the medical staff provided that appointments should be for the calendar year in which the appointment is made. Plaintiff was not dismissed during the year. He was merely notified that his year to year privileges would not be renewed when they expired. In such case no notice, other than that given him, and no hearing, are required. In Levin v. Sinai Hospital of Baltimore City, 186 Md. 174, this court held that a private hospital has the right to exclude any physician from practicing in it and that such exclusion rests with the managing authorities, adding that the directors of a private hospital corporation who have the power to appoint members have the power to remove them from the staff. In that case the court concluded "It is clear, therefore, that since the bylaws of defendant provide that appointments to all divisions of the medical staff shall be made for only one year, appellant has no right to object to his removal from one of the divisions of the staff." We think, concluded the court of appeals, the procedure followed by the board in allowing plaintiff's privileges to expire at the end of the year without renewal was fully in accord with the bylaws of the medical staff and the principles of the Levin case.

The plaintiff also contended that the action of the board was arbitrary, capricious, unwarranted, and unjust. We agree with the chancellor that there was no basis for such a charge, said the court of appeals. The record is replete with evidence that the plaintiff was an obstacle to the control of the hospital by the board, that he was not amenable to discipline, which he often required, and that his presence led to an inharmonious working of the hospital. It is clear that he was either unable, or refused, to comport himself effectively and agreeably within the framework of a charitable hospital conducted on a high plane by a public spirited and sincere board of trustees, as such hospitals generally are conducted and that this attitude created the situation which justified the exercise of an honest discretion by the board leading to his elimination from the scene.

The plaintiff's other contentions were of a more or less technical nature relating to the intent, purpose, and meaning of certain documents adopted by the board, certain documents which passed between the board and the plaintiff, and certain actions taken by the board pursuant thereto. These contentions were also resolved in favor of the hospital. The judgment of the trial court refusing the plaintiff's requests was therefore affirmed. *Glass v. Doctors Hospital, 131 A (2) 254 (Md., 1957).*

Malpractice: Postoperative Care Following Removal of Gall Bladder—Need for Expert Testimony.—This was an action for damages for injuries caused by the alleged malpractice of the defendant physician. The *trial judge set aside a jury verdict in favor of the plaintiff* and entered judgment for the defendant, so the plaintiff appealed to the Supreme Court of Utah.

The defendant removed the plaintiff's gallbladder; there was no negligence in the performance of the operation. Following the operation, however, the plaintiff suffered pulmonary complications allegedly culminating in a collapsed lung, causing pain and suffering and resulting in loss of employment, all of which she attributed to lack of postoperative care. The plaintiff contended generally that the defendant's postoperative care was negligent in that he failed to observe elevation of pulse and temperature and to take remedial measures, that he failed to observe the pain plaintiff suffered, which required sedation, and that he failed to take x-rays to determine the cause of continued chest pains. None of these claims of negligence, said the Supreme Court, was supported by any expert testimony. Whether an attending physician exercised the ordinary care, skill, and knowledge required of doctors in the community which he serves, continued the Supreme Court, must ordinarily be established by the testimony of physicians, except when the facts may be ascertained by the ordinary use of the senses of lay witnesses. Care of a patient after a gallbladder operation, however, depends upon complex scientific knowledge and cannot be ascertained by common lay knowledge.

The plaintiff's principal contention of negligence in postoperative treatment was that she was not "turned and coughed" in accordance with accepted medical standards. The defendant, testifying as an adverse witness, explained that after upper abdominal surgery, when the abdominal muscles are painfully used, the tendency exists to breathe shallowly and if this continues a partial filling of the lung cells and an eventual collapse of the lung may result. Deep breathing and coughing, he said, tend to loosen the accumulated matter and aid in using the full capacity of the lung. The defendant further testified that the medical standards of physicians within the community would require coughing and turning somewhere between every two hours, the routine maximum standard, and every six hours, the minimum standard. The hospital record does not specifically note that the plaintiff was "turned and coughed" as such as often as once every two hours, admitted the Supreme Court, but it does show orders entered and services rendered which necessarily involved movements of the abdomen and chest, such as giving shots, baths, and enemas; "being made comfortable"; inserting rectal tubes; and being catheterized. In fact, the hospital record disclosed 18 of such services in a period of 43 hours. In view of this evidence, continued the court, no finding could reasonably be made that the patient was not turned and coughed at intervals sufficiently frequent to meet even the maximum standard testified to by the defendant. Furthermore, the court pointed out, the defendant gave orders for regular turning and coughing as well as for other treatment and medication. If *such orders were not carried out, the failure to do so* was the responsibility of the hospital personnel and not the defendant, unless the knowledge of such laxity was in some manner brought to his attention and he failed to take steps to remedy the situation. There was no evidence that the defendant had such knowledge. The judgment of the trial court in favor of the defendant physician was accordingly affirmed. *Huggins v. Hicken, 310 P. (2d) 523 (Utah, 1957).*

Malpractice: Trial Court's Instruction as to Effect of Malpractice Judgment on Physician's Reputation:—This was an action for damages for injuries caused by the alleged malpractice of the defendant physicians. There was judgment for defendants and the plaintiff appealed to the Supreme Court of Florida.

The plaintiff contended that the trial court erred in giving the following charge to the jury at the request of the defendants: "In a case against a physician for malpractice, the professional character and reputation of the physician is the most important matter at stake, and hence he should not be condemned by evidence that does not point to his negligence." If the trial court had allowed physicians to testify that a judgment against a physician in a malpractice case would result in great injury to the professional character and reputation of a physician, the admission of such testimony would have required a reversal, said the Supreme Court. The giving of the questioned charge was an even greater error because it was a statement by the trial court to the jury that, in considering their verdict, even should they conclude that the physicians had been negligent and that such negligence proximately contributed to the plaintiff's injuries, they were entitled to weigh against that the effect that their findings and verdict would have upon the professional character and reputation of the defendants. The court held that the giving of such charge was reversible error because it misled the jury. Accordingly, the judgment of the lower court in favor of the defendant physicians was reversed and the cause remanded. *Stauf v. Holden, 94 So. (2d) 361 (Fla., 1957).*

MISCELLANY

The following article was prepared by the valedictorian of the 1957 graduating class of the Olivia, Minn., High School. She received $1,000 for winning first prize in the National Essay Contest which is sponsored by the Association of American Physicians and Surgeons in cooperation with state and county medical societies. The author intends to use her prize money as a premedical student at the University of Minnesota.—ED.

THE ADVANTAGES OF PRIVATE MEDICAL CARE

Sonia Gustavson

"May the love for my art actuate me at all times; may neither avarice, nor miserliness, nor thirst for glory, nor for a great reputation engage my mind; for the enemies of Truth and Philanthropy could easily deceive me and make me forgetful of my lofty aim of doing good to Thy children."[1]

The art of medicine is the Great Art. Its practicers are dedicated; its appreciators are fervent. Surely it is the wish of all thinking, discerning men that members of the medical profession know an atmosphere which will enable them to maintain the high quality of health care that they are giving Americans at the present time. That atmosphere is one which is free from government control or intrusion. American medical men possess this freedom now, and they must continue to possess it. . . .

Since the founding of our nation, life expectancy has increased 39 years. . . . Since 1900, the death rate has increased for 8 diseases, while it has decreased for 21. . . . The increase is due to the fact that, since that year, the population of America has doubled. For every 1,000 babies born in 1957, some 130 live who would have died 50 years ago. The number of people over 65 has quadrupled, and these people account for the marked rise in the death rates for cardiovascular diseases, cancer, and other diseases of old age. The decrease is due to the discovery and perfecting of antibiotics, improved surgical methods, quicker diagnosis and reporting, and to the work done in the field of preventive medicine.

Such splendid achievements could not arise from a profession with low standards of quality. The medical profession requires of its prospective members ten years of advanced education in any of the nation's 82 approved medical schools and under intern and residency programs. Post-graduate courses are offered by schools, societies, hospitals, and other health agencies. Standards are elevated in auxiliary fields of medicine such as laboratory technology and occupational therapy. Financial aid can be secured by deserving medical students. A record number—7,686—entered medical schools in the 1955-56 academic year. What may appear to be, *in some areas,* a shortage of doctors, in actuality is maldistribution. This is being remedied by placement programs which inform communites of doctors desiring locations and inform doctors of communities desiring medical care.

One of the arguments for socialization of medicine frequently used by uninformed people is this: "If the government takes control of medicine, we'll get free medical care." Medical care, like every other necessity, costs money. There is no reason why anyone should hesitate to go into debt to meet medical costs. There are three ways that a man can pay for medical care.

(1) Cash. It is cheaper to pay for home or office calls than to pay taxes to the government on the chance that you might need this kind of service. (2) Savings, securities, loans. Should a man find it necessary to delve into his savings to pay a medical bill, he can do so. If this is not necessary, the savings will remain on hand to meet other types of expenses that may arise. If medical bills were met with federal taxes which are, in this case, compulsory savings, a man could not use these funds for any purpose other than to meet medical expenses. (3) Commercial insurance. In exchange for premiums, you are paid for the costs of more serious illnesses and operations. The uncertainty of a large expenditure is replaced by the certainty of a small one. The advantage of voluntary health insurance over compulsory health insurance is this: The individual reserves the right to select his own doctor and hospital. At the present time, over 60% of the estimated eligible population carries some type of voluntary hospital expense coverage, and approximately 50% is protected against some of the insurable costs of surgery. The voluntary health insurance movement has already surpassed the goals originally charted by the pioneers in the field. It has been on a voluntary basis that all great progress in America has been achieved, and only on that basis can the nation be assured of progress in this field.

A look at the country of England will show us some of the dire results of the socialization of medicine. Under the National Health Program, that country proposed to give the indigent, the poor, the average, and the wealthy the same quality and quantity of medical care, and maintain the quality and quantity that the wealthy were accustomed to under private practice. What happened? In London, wealthier districts have an average of one doctor for 1,261 patients, and poor districts have twice as many patients per doctor. The farming and mining communities suffer even more from lack of medical services. In February of this year, the British Medical Association advised 21,000 English general practitioners seeking a pay raise to quit Britain's socialized system of medicine. The Association recommended . . . a pay-as-you-go plan.

From bitter experience, Britain has learned some of the inevitable results of government medicine. (1) Administrative costs of collecting the taxes and redistributing them as sicknesses occur make the entire program less than worthwhile. (2) The physician patient relationship, always confidential, has been disturbed by this third party intruder, the government. (3) Physicians lose autonomy in diagnosis and treatment that they possess in private practice. (4) Political nfluences enter into the sphere of medicine. (5) Regimentation occurs in conditions of employment for doctors: the number of hours they must work, their income, and their location. (6) Standardizing the treatment of patients slows down research.

Should anyone feel that the indigent and the chronically ill are being neglected under America's present system of medicine, let us investigate these areas. The chronically ill are, of course, excluded from private medical plans because the risk is too great. However, in this country there are private institutions that give considerable amounts of aid to the aged, the sick and the handicapped. Doctors often treat these people at reduced costs. Indigent people . . . are the only people who should receive government aid. If the government stepped in to furnish all of us with medical care, all private resources would dry up and the taxpayer would have to shoulder the entire load. The government already takes one-third of our income, so why make it necessary for it to take more, when private medicine is less expensive and so much more efficient. Let us not forget that it is the intrinsic nature of bureaucracies to get bigger and bigger, more and more wasteful, costlier and costlier and, at the same time, to get further and further out of touch with the individual and his or her particular needs.

In 1939, in a small country town, a woman was stricken with simultaneous influenza and pneumonia. For several days her life hung by a thread, and during these days her family doctor . . . was available to administer stimulants when it seemed the thread could hold no longer. As a last resort, this country doctor sent to a larger city for a new drug that had just appeared on the medical scene which, through his constant studying, he had just learned about. This forerunner of the "miracle" drugs—sulfanilamide—along with the doctor's dedicated care, saved the woman's life.

Picture the same case under socialized medicine. During the day, the doctor would have been too harassed by petty rules and regulations of diagnosis and treatment to give his undivided attention to the saving of this life. After hours, when stimulants were needed immediately, the "night doctor" would have had to have been called. In all likelihood, there would have been no case-continuity nor any of the vitally important feeling for the patient on the part of the "night doctor" working his "shift." When the new drug was wanted, there would have been red tape to cut, and forms and requisitions to fill out. By the time the drug would have arrived, the thread of life would have been completely and finally severed.

When I see this woman now . . . it seems to me that she is a living embodiment of the advantages of private medical care.

THE LEISURE CORNER

CREATING A LIBRARY OF MUSIC RECORDS

Interest in recorded music has shown such tremendous growth in recent years that home record libraries have become an invaluable and meaningful hobby. While trained musicians and seasoned concert-goers know precisely what music they want to own, there exists a large group of persons, including physicians, who have an innate love of music but who hesitate to venture beyond the realm of the semiclassical or popular song hits. By starting a record collection, these individuals can readily increase their understanding and love of the classics through repeated playing of music that has been recorded by outstanding interpreters.

To be "at home with music" by virtue of a library of records implies establishment of an unashamed expression of personal taste. This has not always been true of specially trained and privileged music lovers of the past. Listening to music was often regarded as a duty rather than a pleasure, an earmark of cultural and social superiority. Today, to the purchaser of music records, listening to these records takes on the added pleasure of independence of selection. This type of person is not necessarily concerned whether he is found in the company of other music lovers, nor does he have to go into a technical discussion of musical details. He merely purchases music that he likes or that has been recommended to him by those whose opinion he respects. The fact that he willingly pays for his recorded music is self-explanatory. It is only out of the care that he devotes to creating a musical library, without cluttering up a household with albums that represent false musical pretensions rather than personal selection and taste, that pleasure actually comes.

In creating a library of music records, it is best to commence with music that you know and like. Then, going on from this vantage point, one may purchase records that are related in their musical nature, while proceeding to more highly developed musical compositions. If you are the sort of person who "can't get warmed up" to classical music, you might start your musical adventure with simple melodic waltzes, the more rhythmic types of music, or some of the old favorites. A record library should be so arranged and built that you will be able to derive equal or greater pleasure from purchases made 10 years before. It is highly important to collect records at one's own musical level, keeping an eye and an ear on recordings that are lasting and worthwhile.

An initial group of records can be planned about the Strauss waltzes. These waltzes are frequently admired for their whirling rhythms and lovely melodies, and they seldom fail to captivate the listener. The "Blue Danube" is probably the most popular of all

Strauss waltzes. If one is interested in obtaining a small number of Strauss waltzes, consideration should be given to "De Fledermaus," "The Emperor Waltz," and "Der Zigeunerbaron" ("The Gypsy Baron"). The album called "Johann Strauss: Two Overtures and Two Waltzes" contains some of the best known and best loved of all Strauss music. The "Fledermaus" and "Zigeunerbaron" overtures consist of medleys of tunes from these operettas, each reaching a climax with a waltz.

As you grow in musical taste and discrimination, you will find that Tchaikovsky and Grieg are two composers whose recordings will give considerable pleasure. The waltz from "Serenade for Strings" by Tchaikovsky is a smoothly flowing, highly melodic composition, entirely different from Viennese waltzes, as it is quiet and subdued and the stringed instruments sing forth in a manner that makes it almost irresistible. The other side of this particular record contains an attractive recording by Grieg called "The Last Spring." Some of the more tuneful melodies were never actually composed by a single person; they literally sprang from an entire people, and were handed down vocally from one generation to another as "folk music." In the United States, the best known example stems from southern Negroes, and an excellent recording of this type of music has been made by Columbia.

If, by this time, you feel you are ready for opera, you will find that the two most popular composers are Verdi and Puccini. Both composers wrote melodic arias that attach themselves to one's memory, and you will find yourself before long humming them on your way to your office. The tender passages of "Celeste Aida" will lead you to the robust jovialty of "La donna e mobile." At this point, you should be just about ready for music by a famous French impressionist composer, Claude Debussy. For the most part, Debussy's melodies are comprised of an entirely different texture from those you have been listening to. There is a mysterious, sensitive tone quality about the work of this composer, and it is best to buy his simpler recordings—for example, "Clair de Lune." It would be well to compare the original piano version of "Clair de Lune" with the arrangement for orchestra before choosing a record. The piano impression is more somber.

For an attractive and varied collection of dances, try the album recorded by the Philadelphia Orchestra. "Pops" records will give many hours of delight. The "Russian Sailor's Dance" (from the ballet "The Red Poppy") is a characteristic bent-knee affair that starts off slowly and increases in speed until it winds up in a whirlwind finish. The same 12-measure theme is repeated over and over again, and is varied each time with new tempo and new orchestral coloring.

By now, you should be well on your way to the appreciation and enjoyment of another concept of music. By listening to symphonies in their entirety, one is able eventually to appreciate fully the more advanced interpretation of orchestral repertoire.

A library of records is incomplete without some chamber music. This wonderful form of musical expression has intrigued many physicians, and many, all over the country, have organized groups to play chamber music. An intimacy and completeness surrounds chamber music, and it is a form of music admirably suited to reproduction on the phonograph. Chamber music was originally written for performance in the intimate surroundings of the home. Some people feel cool to this form of music because they probably have listened superficially to some of the more profound compositions without having become familiar with attractive, yet less complicated works. "The Quinte for Clarinet and Strings" by Mozart is filled with delightful melody. The liquid tones of the clarinet blen harmoniously with the two violins, viola, and cello o the string quartet, producing an engaging tonal effect Once you have become converted to the joys of listening to chamber music, you will find yourself investin in many records of string quartets. If you are a mus cian in your own right, much pleasure may be derive from accompanying these recordings with your ow instrument.

Whether you are interested in music arranged f the concert hall or for the opera, you can sample ever type in the quiet of your own home. By the time yo have made friends with the majority of classic recordings, you will probably be enough of a musical enthusiast to approach more complex types of music. library should be built in a planned, musically intell gent fashion. Most persons prefer to acquire a fe records at a time, becoming thoroughly acquainted with them through repeated playing. Some like an entire library selected for them; they have a specified amount of money to spend and desire a balanced group of records.

As is true of any collection, a record library requires a certain amount of care. Records should be handled at the edges if possible, as repeated handling of the surfaces will cause records to sound gritty and swishy. Surfaces should be cleaned with a record brush or cloth. The most common ailment of records is warpage. Warped disks can be made flat again by placing them in direct sunlight for five minutes and then placing them, one by one, on a very flat surface under the even weight of several books.

New records should be examined very carefully. They should have a shiny, clean surface, free from scratches, dents, and blemishes. Cracked records should never be played, since the repeated striking of the cracked surface against the point of the needle can damage both needle and pickup arm. Each record requires a certain amount of breaking in; this usually involves no more than playing it all the way through and then dusting it thoroughly with a record brush. As a collection of records grows, storage becomes important. Records should be stored vertically and kept away from direct heat.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Listeria Meningitis, A Report of Eight Cases. J. W. Dedrick. Am. J. M. Sc. 233:617-621 (June) 1957 [Philadelphia].

Eight patients with listeria meningitis were admitted to the communicable disease unit of the Los Angeles County Hospital within 4 years; 4 died and 4 completely recovered. All received penicillin and sulfonamides, and all but one received chloramphenicol as initial therapy. Sensitivity tests showed organisms from survivors to be responsive in vitro to a larger number of antibiotics than those from patients who died. Afebrility was finally obtained in 2 of the 4 surviving patients after substitution of oxytetracycline for virus-resistant chloramphenicol. The striking morphologic resemblance of listeria monocytogenes to diptheroids and the colonial similiarity on blood agar to beta streptococci have caused many cultures to be either discarded or incorrectly identified, leading many to believe that human listerosis is far less common than it really is. The differentiation of listeria monocytogenes from diptheroids and beta streptococci may be accomplished on the basis of motility, virulence in mice, keratoconjunctivitis in rabbits (diagnostically specific for listeria monocytogenes), and serology. In vitro testing of the variable sensitivities to antibiotics is important in the choice of individual therapy.

Serum Transaminase in Pulmonary Disease and Multiple Infarctions. J. R. Walsh, F. L. Humoller and F. G. Gillick. Ann. Int. Med. 46:1105-1112 (June) 1957 [Lancaster, Pa.].

Three hundred eighteen determinations of serum transaminase activity were carried out in 112 hospitalized patients, 50 of whom showed evidence of myocardial infarction. These determinations were made with the aid of Karmen's spectrophotometric method in an attempt to determine the specificity of the serum transaminase test in patients with myocardial infarction. While increased serum transaminase levels were found most commonly in patients with acute myocardial infarction, elevated levels also were found often enough in patients with necrosis and infarction of other organs to suggest caution in interpretation. The highest values of 500 units or more of serum transaminase activity were found in patients with multiple pulmonary and renal infarcts. The typical curve for the time course of serum transaminase levels of myocardial infarction also was observed in patients with multiple pulmonary and renal infarcts. In patients with pulmonary infarction, increased serum transaminase levels ranging from 40 to 100 units were observed, particularly after the 4th day. In certain cases the increased serum transaminase level became evident between the 6th hour and 5th day, exactly as in patients with myocardial infarction. These observations definitely reduce the usefulness of the test for the differentiation of myocardial from pulmonary infarction. The occurrence of serum transaminase levels of more than 100 units, however, was rare in patients with pulmonary disease. There were only 2 such cases among the 112 patients. A value of 186 units was recorded in 1 patient with fulminating pneumonia and a value of 104 units in a patient with pulmonary infarction. Increased values of more than 40 units of serum transaminase activity were observed in patients with pulmonary infarction, multiple infarctions, pneumonia, carcinoma of the liver, pancreatitis, trauma, and cirrhosis of the liver and in 1 patient with uremia.

Clinical Manifestations of Hypopotassemia. B. Surawicz, H. A. Braun, W. B. Crum and others. Am. J. M. Sc. 233:603-615 (June) 1957 [Philadelphia].

Patients with abnormally low concentrations of plasma potassium may have numerous functional and anatomic derangements. However, the majority of the signs and symptoms related to hypopotassemia are nonspecific, being found in many severely ill persons without low potassium levels. Multiple disturbances of homeostasis complicate potassium deficiency, obscuring and modifying its effects. The incidence of hypopotassemia among females was significantly higher than in males. The mortality rate of hypopotassemia patients was much higher than the over-all hospital rate. Hypochloremic alkalosis with hypocalcemia commonly accompanied patassium deficit. Anorexia, nausea, and vomiting are part of the clinical symp-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1948 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

tomatology, which included inactivity of the deep tendon reflexes as the only factor correlated with potassium deficit. A rough correlation exists between impairment of intestinal peristalsis and degree of potassium deficit. The most significant changes accompanying rapid infusion of potassium were increased peristalitic activity and improved mental status. The nonspecific nature of clinical manifestations of hypopotassemia emphasizes the importance of the electrocardiogram, the electromyogram, and other laboratory aids in the diagnosis of this disorder.

Molecular Diseases of Hemoglobin: I. Introduction and Incidence. T. P. Haynie, H. L. Dobson and R. A. Hettig. Ann. Int. Med. 46:1031-1038 (June) 1957 [Lancaster, Pa.].

The incidence of abnormal hemoglobins was studied by the authors with the aid of paper electrophoresis in 350 white and 400 Negro patients at the Jefferson Davis Hospital, in Houston, Texas. The results obtained were compared with those obtained by Smith and Conley in 500 white and 500 Negro patients at the Johns Hopkins Hospital and by Schneider in 60 white and 505 Negro blood bank donors at the John Sealy Hospital in Galveston. The authors' study and that of Smith and Conley, representing the incidence in general hospital populations, agreed quite well. The study by Schneider differed in that persons with known hemoglobin disease did not appear in this series, which was based on blood bank donors, since persons with overt hemolytic disease or anemia were not permitted to donate blood. Persons with asymptomatic trait abnormalities, however, were included, and Schneider's statistics thus provided a good indication of the incidence of trait abnormalities in a population considered to be normal.

Abnormal hemoglobins were not found in any of the 910 white persons screened by electrophoresis in the 3 studies. In the 1,405 Negroes, there was an incidence of 11.5% of abnormal hemoglobins as detected by electrophoresis. S hemoglobin was present in 9.4% and C in 2.2% of the Negroes. Only 1 case of homozygous C disease was detected in the 3 series. The incidence of the sickle trait varied from 7.2% to 11.3% in the 3 series, with a mean of 8.4%, thereby providing essential agreement of trait incidence between electrophoretic techniques and those based on the findings of in vitro sickling reported by other workers. The figures from all 3 series combined agreed quite well with the notion that about 10% of the Negro population has sickle cells in the peripheral blood and that 10% of this group has sickle cell anemia.

Filter-paper electrophoresis is the best single method for the detection of molecular diseases of hemoglobin. This method will separate all but combinations of A, F, and G hemoglobins and combinations of S and D hemoglobins. The most common abnormal hemoglobin is S, while C is observed less frequently. The diseases observed were trait, homozygous disease, and double heterozygous disease. The incidence of molecular disease of hemoglobin in Negroes is about 11.5%.

SURGERY

Cerebral Damage After Metatraumatic Ligation of Carotid Artery. U. Venzlaff and E. Trostdorf. Beitr. klin. Chir. 194:328-349 (No. 3) 1957 (In German [Munich, Germany].

Ligation of the carotid artery was performed after injuries involving the carotid artery in 16 patients. In 15 patients these injuries were sustained during World War I and in 1 patient in a traffic accident. Ligation of the common carotid artery was performed in 10 patients; ligation of the common carotid and internal carotid arteries in 3; and ligation of the internal carotid artery, of the internal and external carotid arteries, and of the external carotid artery in 1 each. Ligation was done on the left side in 11 patients and on the right side in 5. Complete contralateral pyramida hemiplegia resulted immediately or within 2 hours t 5 days in 11 of the 16 patients; it was permanent in 7 and one of the 4 patients who gradually improve made a complete recovery. Two additional patien had symptoms of latent hemiplegia, such as abnorma reflexes and mild dysdiadochokinesia. Only 3 patien did not have any pyramidal signs. All the patients wit pyramidal hemiplegia also showed signs of involvement of the corticobulbar tracks. Of 8 patients wit pyramidal hemiplegia resulting from ligation of th carotid artery on the left side, 7 had aphasic disturbances of speech. Motor aphasia was predominant. Th most severe and refractory disturbances of speec were observed in 3 patients over 25 years of age wit combined motor-sensory aphasia. Gradual improvement resulted in the other patients. Weakness in wri ing and reading occurred in 3 patients. Blindness o the side of the focus resulted from atrophy of the opt nerve in 1 patient. The atrophy may have been cause by spasm or embolism of the central retinal arter blocking the circulation.

There was a constant relationship between the e tent of the psychic disturbances and the severity of th neurological deficiencies. Psychic disturbances we more severe in older patients and in those with ligation at the left side. Of the 5 patients with ligation a the right side, only the oldest, a 39-year-old man, ha affective disturbances of regulation, slowing down and a tendency to depression. Of 11 patients with ligation on the left side, 9 had severe psychic disturbances, including mental deterioration, characte changes, and functional weakness of the brain. Only the 2 youngest patients, who had been operated on at the age of 20 years, were free from psychic disturbances.

Late complications were observed after free intervals of from 1 to 9 years. Headache, vertigo, tendency to collapse, and sweating were observed in 4 patients ho first did not have any encephalopathic complaints ter the operation. These complaints became gradu-lly worse, and functional weakness of the brain eveloped in 2 patients whose memory and concen-ation weakened. Symptomatic epilepsy occurred as late complication in 4 patients, and a decrease in bido and potency in 1 patient. Nine years after the gation 1 patient had sudden attacks of feeling of nnihilation, vertigo, blackout, and temporary worsen-ng of his residual paresis in the right arm. These ob-ervations show that ligation of the carotid artery is ndured only in very rare cases without causing a leficiency in the blood circulation of the brain which nay, occasionally, develop only years after the opera-ion.

)irect Vision Repair of Intracardiac Defects Utilizing Rotating Disc Reservoir-Oxygenator. F. S. Cross and . B. Kay. Surg. Gynec. & Obst. 104:711-716 (June) 957 [Chicago].

Many pump-oxygenator systems have been devised or intracardiac operations for the repair of congenital ardiac anomalies. The basic mechanism of the rotat-ng disk reservoir oxygenator, used in the 45 patients perated on for intracardiac defects during the first 10 nonths of 1956, is a series of 59 silicone-coated stain-ess steel disks supported horizontally in a pyrex ylinder coated with silicone resin. Blood introduced t one end of the cylinder is removed from the bottom f the opposite end. The rotation of the disks prevents he channeling of blood along the bottom of the cylin-ler. With the oxygenator primed with 1,400 cc. of vhole blood and the disks rotating at a rate of 120 pm, there is an exposure area of 108 sq. m. per min-ite. A mixture of oxygen and 1.5% carbon dioxide, varmed in a sand bath heated by an electric mantle, s supplied. Continuous monitoring of central venous ressure and maintaining it at the preperfusion level onstituted the greatest aid in achieving a balanced erfusion during the periods of cardiac bypass. Any nmeasured extrinsic blood loss or reflex vasodilatation esulting in decreased venous return to the cavae and concomitant decrease in the venous return to the xygenator automatically is compensated for with lood from the reservoir-oxygenator and is measured s a fall in the oxygenator blood level. In this way the entral venous pressure acts as a fairly accurate index f the circulating blood volume in the patient. After ardiotomy closure the caval tapes are released and the ump rate decreased slowly, with a satisfactory central enous pressure and systemic arterial pressure main-ained until the heart takes over satisfactorily. The atient is weighed immediately postoperatively, and he weight is adjusted by means of blood transfusions r blood removal if necessary.

The greatest experience to date with the intracar-liac repair techniques has been with ventricular septal lefects, atrial septal defects, and pulmonic stenosis, alone or in various combinations. Ivalon sponge prostheses have been used in the repair of the larger ventricular septal defects, whereas the smaller defects have been closed by interrupted sutures of 000 silk. Atrial septal defects have been closed by direct suture by use of either interrupted sutures of 000 silk or a continuous suture reinforced with interrupted sutures. Thirty-three of the 45 patients survived the operation. No deaths could be ascribed to the use of the pump oxygenator. Pulmonary complications were the most frequent postoperative problem. There can be little doubt that the future of cardiac surgery lies in the further development of safe direct-vision techniques. The advantages of the open techniques are (1) easy visualization of all valves, septums, and chambers; (2) complete correction of existing defects when possible; and (3) identification and repair of associated defects previously undiagnosed. Where there has been an opportunity to compare open techniques with previously tried closed techniques, the former have proved more satisfactory from all standpoints. Emphasis is placed on the use of extensive physiological studies before, during, and after the period of cardiac bypass, for it has been through these studies that the techniques of surgery under direct vision have been improved. A satisfactory pump-oxygenator is only part of the formula of success.

Surgical Repair of Ruptured Interventricular Septum Following Acute Myocardial Infarction. D. A. Cooley, B. A. Belmonte, L. B. Zeis and S. Schnue. Surgery 41:930-936 (June) 1957 [St. Louis].

Rupture of the interventricular septum resulting from or secondary to myocardial infarction is widely recognized as a fatal complication of acute coronary occlusion. Septal rupture occurs approximately 7 days after acute infarction, with death resulting from rapidly progressive cardiac decompensation. A loud precordial systolic murmur appearing after a coronary occlusion is of diagnostic significance, as emphasis is placed on early diagnosis, vigorous treatment of cardiac decompensation, and prompt preparation for operation within the time interval (several hours or days) between septal rupture and ultimate cardiac failure. Diagnosis may or may not be confirmed by catheterization. Direct surgical correction of this defect and other serious complications of acute myocardial infarction, such as ventricular rupture with pericardial tamponade, ventricular aneurysm, and ruptured papillary muscle, is now feasible with the use of temporary extracorporeal circulation.

Pericardial Fat Necrosis: Report of 3 Cases. R. C. Jackson, O. T. Clagett and J. R. McDonald. J. Thoracic Surg. 33:723-729 (June) 1957 [St. Louis].

The authors report on 3 patients, 2 men aged 52 and 63 years, respectively, and 1 47-year-old woman with pericardial fat necrosis. Each patient was quite ceded by conization biopsies negative for evidence of cancer. There were no deaths to date that could be attributed to carcinoma in situ of the uterine cervix.

The diagnosis of cancer in situ is possible only if the 360-degree cold-knife conization biopsy technique is carried out in every patient with suspected cervical malignancy. Total hysterectomy and resection of a generous vaginal cuff with preservation of normal-appearing ovaries in all women aged less than 45 years is the treatment of choice in those with a conization biopsy positive for cancer in situ of the uterine cervix. Any other form of therapy is considered inadequate, as evidenced by the high incidence of residual tumors noted in this series. The presence of glandular involvement in the conization biopsies did not appear to affect adversely the prognosis over a 5-year period nor to increase materially the incidence of residual tumor in the postoperative specimen. Extensive glandular involvement by noninvasive cancer in the conization biopsy is considered to be a more advanced stage of the disease from the standpoint of microscopic pathology but it does not constitute invasion of the underlying stroma nor adversely affect long-range prognosis in any patient. The incidence of residual tumor in this series is thought to be due to incomplete removal of the tumor by conization biopsy, to its possible multicentric origin, or to a combination of both, and not to involvement of the endocervical glands.

Carcinoma of the Vulva. J. H. Isaacs and N. H. Topek. Am. J. Obst. & Gynec. 73:1277-1285 (June) 1957 [St. Louis].

Of 41 women with carcinoma of the vulva seen in the course of 17 years, 18 (43.9%) were seen during the last 5 years. These data suggest that with the over-all increase in life expectancy there has been a concomitant rise in the incidence of vulvar malignancy. Six of 16 patients who were followed up for 5 years or more were living and well, a 5-year survival rate of 37.5%. This result was due to inadequate therapy employed in some of the earlier cases. Of 11 patients adequately treated either by radical valvulectomy and irradiation or by radical valvulectomy and lymphadenectomy, 6 survived for 5 years, a survival rate of 54.5%, which approaches an acceptable percentage.

A critical survey of the symptomatology of the patients with carcinoma of the vulva indicates that it is a disease of older women and of slow development, and that chronic irritative lesions of the vulva are predisposing factors. Such precancerous lesions must therefore be excised. Patients with coexistent carcinoma of the vulva and veneral granuloma generally have a better prognosis, since the accompanying inflammatory adenitis blocks the lymphatic pathways, preventing metastases. When vulvectomy is done for precancerous lesions, the specimen must be cut for multiple section study, as previously undetected malignancy may be found. If discovered, then bilateral groin dissection is essential. Radical surgery is the only means of increasing the 5-year cure rate. T extent of the surgery will depend on the condition the patient and the extent of the disease. A 1-st procedure including radical node dissection and v vectomy as advocated by other workers is ideal the reported 12% operative mortality suggests 2-st or even 3-stage operations may be best in poor- patients. The exenteration operation advocated for t treatment of patients with far-advanced disease i volving the intestines and/or the bladder resulted an alarmingly high operative mortality of 45%, wh makes this method not yet practical.

OPHTHALMOLOGY

The Treatment of Retinoblastoma by Radiation a Triethylene Melamine. A. B. Reese, G. A. Hyman, G. Merriam Jr. and A. W. Forrest. Am. J. Ophth. 43:86 871 (June) 1957 [Chicago].

The treatment of retinoblastoma by combination x-radiation and triethylene melamine is more effecti than treatment by x-radiation alone. Results of t combined treatment are more favorable from a stan point both of vision restored and of minimal ti lapse from commencement of treatment. TEM e ployed intramuscularly, either by itself or in com bination with x-radiation, is more effective than wh employed orally, due to emesis, irregularity of a sorption, and resultant interference with dosage. T lower dosage of x-radiation now required in the com bined treatment has led to no vitreous hemorrhag such as are encountered with the dosage required i deformities. Multicentricity of foci did not affect t cure rate in either group. A failure of the combin group in lesions of 5 disk diameters or less was ra while in lesions greater than 8 disk diameters the were failures by both methods. Use of TEM intr arterially is indicated as being most effective. T method is used to increase many fold the amount drug reaching the tumor when the tumor is large a enucleation not possible, when there are tumor ce present at the cut end of the optic nerve at enucleatio and in orbital recurrence following prior enucleatio

Use and Misuse of Acetazoleamide (Diamox) in t Treatment of Glaucoma. P. A. Chandler. A. M. Arch. Ophth. 57:639-643 (May) 1957 [Chicago].

The use of acetazolamide (Diamox) has been wid spread in the treatment of glaucoma, since this ca bonic anhydrase inhibiting drug has a pressure-lowe ing effect. But this is due solely to a lessening of t rate of aqueous humor production. The obstruction to outflow of aqueous humor is not influenced by t drug. Treatment of glaucoma by the use of Diam must be, therefore, regarded as a palliative one. It often of great value in preventing damage to visio while other measures are employed to relieve t fundamental difficulty: obstruction to outflow aqueous humor. The greatest field of usefulness of the drug is in the treatment of secondary glaucoma, which is, by definition, a rise in ocular tension secondary to some other eye disease. If the fundamental disease can be cured, secondary glaucoma is likewise cured. Diamox appeared to be of great value as a substitute for palliative operations. There is no contraindication to its use, except for the unpleasant side-effects experienced by some patients.

The situation is quite different in patients with angle-closure glaucoma, since the obstruction of outflow is due to closure of the angle. In the early stages a simple surgical procedure effects a complete cure of the disease, whereas it is well recognized that in the late stages all treatment may fail. If Diamox, therefore, is employed along with miotics in the treatment of angle-closure glaucoma, the level of tension is no longer a guide as to the extent of closure of the angle. The drug should never be used as a continuing treatment in any form of angle-closure glaucoma, but, once operation is decided on, Diamox serves a very useful purpose as an immediate preoperative treatment in all types and stages of angle-closure glaucoma. No contraindication to the use of the drug is given when there is the question of controlling the residual increased tension.

Report of a New Carbonic Anhydrase Inhibitor (Squibb-MC-9367). M. H. Balistocky and B. C. Gettes. Am. J. Ophth. 43:730-735 (May) 1957 [Chicago].

A single dose of 500 mg. of a propanyl derivative of acetazolamide (Diamox), known as Squibb N (5-sulfamoyl-1,3,4-thiadiazole-2-YL) propionamide, or MC-9367, was given orally to 30 patients with 43 glaucomatous eyes. Of the 43 eyes the glaucoma was of narrow-angle type in 13, wide-angle type in 19, aphakic in 5, secondary to uveitis in 2, secondary to vascular occlusion in 1, secondary to a dislocated lens in 2, and secondary to intumescent cataract in 1. Twenty-three patients with 40 nonglaucomatous eyes were used as controls and were likewise given a single dose of 500 mg. of MC-9367 orally after their intraocular pressures had been recorded. Decreases of 6 mm. Hg or more in the intraocular pressure were considered significant and were observed in 18 eyes of the patients in the control group. None of these patients was receiving miotic therapy.

MC-9367, when combined with the usual miotic drugs, was effective in reducing the intraocular pressure in all 13 eyes with narrow-angle glaucoma, in 16 of the 19 with wide-angle glaucoma, in 3 of 5 with aphakic glaucoma, in the 2 with glaucoma secondary to uveitis, in the 2 with glaucoma due to bilateral dislocated lens, and in the eye with glaucoma secondary to an intumescent cataract. MC-9367 was ineffective in the eye with glaucoma due to vascular occlusion. In no case in which Diamox had failed was MC-9367 effective. The greatest period of effectivity of MC-9367 was from 2 to 4 hours after its administration. None of the patients reported any paresthesias, and no toxic effects were noted after a single dose of the drug. MC-9367 given in a single dose orally is an effective agent in lowering the intraocular pressure in man.

THERAPEUTICS

Acute Immediate Reactions to Penicillin. G. W. Lewis. Brit. M. J. 1:1153-1157 (May 18) 1957 [London].

Acute immediate reaction after injections of penicillins occurred in 12 patients from general practice. They were divided in 3 groups. The first group consisted of 2 physicians; 1 of them had a painful boil inside his nostril and was given an injection of 1 million units of crystalline penicillin followed immediately by one of 900,000 units of procaine penicillin in aqueous suspension. Nausea, swelling of the upper lip, and a greatly accelerated and irregular pulse rate developed 15 minutes after the injection and were followed by loss of consciousness for 2 hours. One week later large urticarial lesions occurred over the entire body. A similar reaction occurred in the other physician after an injection of procaine penicillin in aqueous suspension which he administered to himself. Both men had received many previous injections of penicillin, and it is suggested that the untoward reaction was due to intramuscular injection of penicillin in sensitized persons. Group 2 consisted of 6 patients, 3 men and 3 women between the ages of 34 and 60 years. Two of these patients received crystalline penicillin and 3, procaine penicillin, and the reactions in these were produced by accidental intravascular injection or back-seepage in slightly sensitized persons. The 6th patient had been given an injection of penethamate hydriodide, and his reaction may have been due to the known toxicity of this compound, since subsequent injections of procaine penicillin were given without untoward reactions. The third group consisted of 4 patients, 2 men and 2 women between the ages of 21 and 56, in whom the reactions were caused by accidental rapid intravascular injection of procaine penicillin suspensions.

A scheme for minimizing the incidence and severity of these reactions is outlined. It includes reduction of incidence of sensitization, by confining oral and parenteral administration of penicillin to cases with clear indications and by abandoning topical application of penicillin; careful history-taking; and dermal and intradermal tests with solutions of crystalline penicillin in allergic patients with previous mild reactions. The interval between individual injections of a course of penicillin should never exceed 10 days, the time required for sensitization to become established. Careful technique of injection should be used. All patients who once had an acute immediate reaction from the administration of penicillin should be given a card indicating this fact, and this card should be carried in the wallet or handbag. Suggestions are made for treatment.

BOOK REVIEWS

Human Cancer: A Manual for Students and Physicians. By Maurice M. Black, M.D., Associate Professor of Pathology and Clinical Pathology, New York Medical College, New York, and Francis D. Speer, M.D., F.C.A.P., Professor and Director, Department of Pathology and Clinical Pathology, New York Medical College. Cloth. $7.50. Pp. 273, with 34 illustrations. Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1957.

In this compact volume the authors have accomplished a synoptic presentation of human cancer in terms of its biological behavior correlated with clinical manifestations and indications for treatment. Although they emphasize the importance of the balance between host and tumor as the chief factor in prognosis, they do not neglect the importance of diagnosis and treatment at an early stage when possible. The book fulfills its objective well, particularly in the first five chapters which deal with cancer detection, human carcinogenesis, biological behavior of cancer, biochemistry of cancer, and chemical and radiation therapy. The remainder of the book deals briefly with cancer in anatomic sites and systems and with remarks as to incidence, signs and symptoms, structure, metastases, prognosis, and treatment. In general, these brief and up-to-date reviews of various types of cancer provide valuable information for medical students and physicians with a general interest in the treatment of cancer.

The one defect in the book is a tendency toward dogmatic statements. Examples of this are found in such recommendations as estrogenic therapy for palliation of mammary carcinoma in patients 60 years of age and older, while the generally accepted attitude is the use of antiandrogenic treatment based on physiological age or at five years or more after the menopause. The recommended intramuscular dose of testosterone propionate for palliation of mammary cancer is somewhat greater than that commonly used at present; 50 mg. three times weekly produces the same limited benefits in premenopausal women as does twice this amount. The authors state that only 32% of thyroid carcinomas are of the papillary variety but, in most series, over 50% of thyroid cancers are papillary adenocarcinomas. Hemithyroidectomy is recommended as the treatment for thyroid cancer; there is no mention of the possible advantages of total thyroidectomy. The experience of the authors in chemotherapy of mammary cancer seems to have been more favorable than that of most of the investigators, particularly with respect to triethylene thio phosphoramide, a drug that has been of little value in the experience of most qualified investigators. The volume is well supplied with tables, graphs, and occasional photomicrographs of excellent quality. There is a comprehensive index. An extensive bibliography appears at the end of each chapter.

A Manual of Pharmacology and Its Applications to Therapeutics and Toxicology. By Torald Sollmann, M.D. Eighth edition. Cloth. $20. Pp. 1535. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1957.

This new edition of a textbook, first published at the turn of the century, is written by one of the founders of American pharmacology. As one indication of the speed with which pharmacology i moving, it might be pointed out that probably ove 50% of the drugs in popular use today were no known when the last edition of this book was published in 1948. The aim of this textbook "is t furnish a guide through the complexities of modern pharmacology—the actions and uses of drugs, in association with a critical summary of the chie features of the many contributions made in thi ever expanding field. It is presumably prepare primarily for use by medical students. The book well indexed and, as is to be expected with a boo of this type, it is indexed in terms of drugs rathe than of diseases for which the drugs are used. A in the earlier editions, only the more recent refe ences (in this case those since 1940) are listed. Despite this limitation, about 11,000 references a included in the appendix. The pharmacology drugs and other chemicals of possible medical an biological importance is discussed in the classic manner: origin, chemical and physical propertie absorption, fate, actions, uses, dosages, and th signs, symptoms and treatment of overdosage. Details of experimental findings are given to an exte not found in the usual textbook in pharmacolog thus providing a valuable source of information the researcher in this field. Introductory chapte deal with certain aspects of pharmacy important the prescriber such as prescription writing, fact influencing the intensity of drug action, and cert general fundamental concepts of the mechanism drug action.

As is inevitable in a book of this encyclope nature and in this field, there are some errors a controversial statements. One of these, for instan is the statement to the effect that during digit therapy in mammals the size of the heart is diminished in diastole but only in systole. M writers on this subject now are of the opinion t in human beings, after full therapeutic doses h been given, a decrease in diastolic size results b in normal subjects and in patients with congestive heart failure. Again, in the opening paragraph on digitalis, it would appear that singling out the actions of digitalis effective in overcoming decompensation in valvular cardiac lesions lays undue emphasis on digitalis usage in such conditions. It would have been preferable to cite auricular fibrillation with failure as the outstanding example, as is done later. It is further stated that pigeons tolerate 25 times as much digitalis as do cats on intravenous injection. Reference to the original work cited, however, shows that pigeons are only 25% more tolerant than cats. For the average medical student and practitioner, the ready usefulness of the book would have been improved if more clear-cut comparisons (preferably in tabular form) of drugs having a similar general type of action or use, such as the various members of the digitalis group, the anticoagulants, the antihistaminics, and the opiates had been included. Like its predecessors, this edition will be a standard reference book for students, practitioners, and research workers, not only for the purpose of keeping abreast with pharmacology generally but for the specific purpose of finding what studies have been done, and by whom, on a particular drug or chemical. It is a vast reservoir of pharmacological information.

Practical Psychiatry for Industrial Physicians. By W. Donald Ross, M.D., B.Sc., F.R.C.P., Associate Professor of Psychiatry, University of Cincinnati, Cincinnati. Foreword by Robert A. Kehoe, B.S., M.D., Professor of Industrial Medicine and Director Department of Preventive Medicine and Industrial Health, Institute of Industrial Health and Kettering Laboratory, University of Cincinnati. Preface by Maurice Levine, A.M., M.D., Professor of Psychiatry and Director of Department of Psychiatry, University of Cincinnati. Cloth. $7.50. Pp. 401, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto 2B, Canada, 1956.

Because of the numbers of people contacted and the amount of time spent in employment, industrial medicine possesses an ideal structure for the application of mental health procedures. An average work week is about 25% of the working person's waking time. In view of the fact that these hours are intimately related to the economic security of the country and have special dynamic meanings for the worker himself, it is to be wondered that recognition and growth of the psychiatric side of industrial medicine was so late. The present volume is one of very few to present the multifaceted psychiatric aspects of medicine in the industrial world. The author cites much material from his own experience and from that of physicians in industry at large. He discusses motivation, fatigue and boredom, morale and absenteeism, accident proneness, job stress, and various other industrial medical problems. The first two sections consist of a short orientation in basic psychiatry. Interviewing and history-taking techniques are reviewed. The author cites the 1952 American Psychiatric Association "Diagnostic and Statistical Manual" for classification, and he leans heavily on Levine's "three layer approach" for psychotherapy. Part 3 deals with the place of medicine in industry, allied social sciences, and communications and referrals.

In the 18 chapters devoted to specific problems, many important and provocative concepts are presented. These should be of interest to the psychiatrist attempting to understand his patient and to the industrial physician seeking psychiatric orientation. In-plant and out-of-plant problems may be diagnostically separable, but they are often best understood as cause and effect (in either direction). Psychodynamics and the physician's contribution are discussed in relation to each type of problem. Throughout the book the author makes many interesting generalizations. For example, he compares the value of the neurotic in industry to the canary in mining; he is unusually sensitive to the stresses that affect everyone. Thus, with perception and insight, the industrial physician can forestall more widespread trouble or discontent. Again, the author emphasizes the need for the physician to be a medical advisor to management and to avoid personnel policy matters if he is to be of real value. The physician must be free to learn of the informal organization of his industry via rapport with lower echelons, and he must have access to the top in order to facilitate his communications which require executive action. This volume should be of value to industrial physicians. It should also provide good orientation for psychiatrists who accept referrals from these physicians.

Practical Refraction. By Bernard C. Gettes, M.D., Assistant Professor of Ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Cloth. $6.50. Pp. 170, with 58 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1957.

This book represents an attempt to produce a short manual on the technique of refraction without going into the details of physiological optics on which refraction is based. For that reason the neophyte will not find that this book is adequate for all his needs but should find in it many useful suggestions. While most of the book is clearly written and should be intelligible to the beginning student in refraction, certain parts, such as the description of astigmatism, are likely to be confusing. Most writers on refraction are extremely dogmatic as to the correctness of their own methods and the error implicit in all other methods, but this author is to be congratulated on his broad viewpoint and the recognition that all techniques have their advantages but that experience, skill, and accuracy are the most essential factors. The orthodox method of presentation has not been fol-

PREMATURE ERUPTION OF TEETH

To the Editor:—*A dentist states that a 6½-year-old boy has "teeth that are coming in five years ahead of time" and that these teeth "have so many cavities that he will have no teeth left by the time he reaches adulthood." His deciduous teeth also showed many cavities, and many of them had to be extracted. The dentist feels that this indicates some systemic disease. Complete physical examination reveals a boy who is tall for his age and in excellent physical and mental health. There are no congenital abnormalities apparent nor any evidence of disease. Serum calcium, phosphorus, and alkaline phosphatase levels are within normal limits for his age. A careful nutritional and hygienic history indicates that the child eats well of all foods, including those containing calcium and proteins, meat as well as milk, and brushes his teeth frequently. He does not overindulge in bottled sodas, orange juice, or milk to the extent of spoiling his appetite for meat. His ancestry is mixed Irish, German, and English, so that, for the present, his Irish ancestors are being blamed for his dental difficulties. Please suggest further investigation, possible diagnosis, therapy, and prevention. If each decalcified area is filled as early as possible, is there any reason why the child should lose his permanent teeth any earlier than anyone else?* *Shepard G. Aronson, M.D., New York*

This inquiry has been referred to three consultants, whose respective replies follow.—Ed.

Answer.—Premature eruption of teeth may occur in hypergonadism, which may be secondary to hyperpituitary function or, more rarely, hyperthyroidism. The degree of premature tooth eruption cannot be evaluated, since this information is not available. Blood chemistry findings would not be altered in rampant caries. The diet should be well balanced and low in fermentable carbohydrates.

The patient's dentist should seek the services of a caries control laboratory. The relative susceptibility of this patient to caries and the effectiveness of the caries control procedures can be evaluated by means of counts of lactobacilli. With frequent expert dental care and complete patient cooperation, there is no reason why the permanent teeth should be lost prematurely. Dental caries are related primarily to local environment factors that can be controlled.

Answer.—To begin with, it must be borne in mind that there is extensive variation in the eruption pattern of both deciduous and permanent teeth and that the statement that the teeth "are coming in five years ahead of time" in itself is almost impossible to interpret. The lack of any evidence of a systemic disease would strongly suggest that this child's problem is entirely local. There is every reason to believe that if the extensive caries are managed on the basis of individual cavities the child should be able to maintain many of his teeth well into adult life. The question as to whe er or not each decalcified area should be filled as ea as possible to avoid the loss of more permanent te is the essence of the problem. Certainly this procedu should be followed, and the results should be acce able. It is recommended that good local dental ca be given the child in order to prevent the spread o the carious lesions and to maintain the teeth wh are now forming the dentition.

Answer.—Tooth eruption normally occurs over wide age range around the accepted average. Hype thyroidism and hyperpituitary disease are associat with accelerated tooth eruption. Caries resulting fro systemic disease most often result from defective form ation of enamel predisposing to bacterial erosion of th teeth. From the description this child has no signi cant systemic disease. The early loss of teeth will ofte result in minor degrees of malocclusion, which predis poses to food being trapped and permitting overgrowt of oral bacteria with enamel erosion and caries forma tion. The age-periods 5 to 8 years and 12 to 18 yea are periods of an unusually high incidence of carie The best management in such a case is good oral h giene and early filling of cavities with close supervisi by the dentist. If teeth become so badly diseased th they must be extracted, space retainers should be us to maintain proper occlusion. No accurate progno can be given, but with proper care the child shou have functioning teeth for quite a while.

STEROIDS AND PERITONITIS

To the Editor:—*Please comment on the use of co sone and other steroids in the management of seve peritonitis, such as occurs in cases of ruptured pendix.*

William R. Moses, M.D., Washington, D. C

Answer.—The true value of corticosteroids and c ticotropia in the therapy of peritonitis is unknown. tention has been called to the benefits of the so-call anti-inflammatory and toxin-blocking effects of th hormones, but knowledge of the mechanisms and s nificance of these phenomena is incomplete. Th agents have also been shown to inhibit antibody form tion in some situations, and it is clear that clini evidence of an infection's progression or even an int abdominal catastrophe may be obscured by stero therapy. Thus, the question of their use is controversi

In spite of this contradictory evidence, however, is certain that relative adrenal insufficiency at tim accompanies overwhelming sepsis. To this extent dogmatic statement condemning the use of steroid for peritonitis is unacceptable, and the following polic seems justified and practical at the present time. Th patient suspected of having relative adrenal insu ciency secondary to previous steroid therapy deserv hormone treatment in a stressful situation, such peritonitis, particularly if surgery is contemplated. E clusive of this group, there are patients with periton who do not respond to preparation for definitive surgery by the intelligent use of accepted supportive measures. The addition of steroid therapy in the management of such patients is probably justified. It must be emphasized, however, that these agents are not substitutes for conventional measures. Strict attention must be paid to the surgical, antibiotic, fluid, and electrolyte needs of the patient. The plasma deficit resulting from the peritoneal "burn" must be appreciated and replaced. It is likely that this aspect of treatment is often neglected.

The surgeon responsible for the care of the patient receiving steroids must not be misled by the clinical improvement which may attend such therapy. This apparent improvement should not influence a previously formed opinion regarding the indication and need for surgery. Steroid therapy, once started, should be continued throughout the course of an acute illness. Withdrawal of these agents should be gradual and cautious, and it is suggested that hormonal treatment be terminated before antibiotics are withdrawn. In summary, these agents are not substitutes for either clinical judgment or proper surgical and supportive therapy. Used intelligently and cautiously, they may at times be helpful in the preoperative preparation or the postoperative management of patients with severe peritonitis.

ISOLATION OF PARAKEETS TO PREVENT TRANSMISSION OF PSITTACOSIS

To THE EDITOR:—*In Queries and Minor Notes in the March 9, 1957, issue of* THE JOURNAL, *page 909, under the heading of "Hazard of Parakeets in Hospitals," most pertinent questions in regard to hazards from these birds seemed to be answered except one which seems to be of considerable practical interest. Presumably, the usual custom is to purchase one bird which is then isolated in a cage, entirely away from other birds, in the home, hospital, or elsewhere. How long a period of isolation is necessary so that the bird will be presumed to be unable to transmit psittacosis if it remains healthy?*

Maurice A. Walker, M.D., Kansas City, Kan.

ANSWER.—Incipient psittacosis cannot be detected in psittacine birds except by virus isolation, which requires killing the bird. Apparently healthy parakeets may spread the virus throughout their lives. Latency is essential to the psittacosis parasite to maintain its infection chain. From 5 to 20% of immature parakeets offered for sale may be infected. The majority of these young birds free their tissues of this infectious agent within a few months, but some never lose the virus. During their "convalescence" they may be, or may become, shedders when subjected to certain stresses—adaptation to a different environment, excessive fondling, chilling, and such factors.

The following experiment vividly illustrates that it is impossible to set a definite time at which a parakeet can be declared not contagious. A parakeet fatally infected four older persons before its death from psittacosis; its cagemate appeared healthy. For six months thereafter, when this cagemate was kept in a closed glass cage in the laboratory with a succession of highly susceptible ricebirds introduced at intervals as cagemates, these ricebirds died of psittacosis. After that time ricebirds introduced did not become infected, but 10 months after the latently infected parakeet had been picked up from the household, live virus was found at autopsy in its spleen and liver.

All parakeets offered for sale should be treated for an adequate time with feed containing an adequately high concentration of tetracycline compounds. Tests in aviaries and pet shops have shown that interrupted oral treatment for 15 days with a total of not less than 30 mg. of any tetracycline compound will render the birds noninfectious, and within a month after the termination of treatment the tissues of 95 to 100% of the parakeets will have been freed from the viral agent. Certainly from the standpoint of public health, untreated parakeets should not be allowed in hospitals or households.

MILK CONSUMPTION BY ADULTS

To THE EDITOR:—*A young man, aged 21 years, in good health, has never abandoned drinking milk with his meals. He dislikes coffee or tea and consumes at least one quart of milk daily. Should interdiction be suggested to prevent possible metabolic disturbances or the deposition of renal calculi as he grows older?*

Joseph Backlar, M.D., Richmond Heights, Mo.

This inquiry has been referred to two consultants, whose respective replies follow.—ED.

ANSWER.—Milk is an important source of nutrients which are needed throughout life, and its continued consumption by adults is desirable accordingly. There is no evidence justifying the interdiction of the drinking of one quart a day by a healthy adult on the basis that this use might cause metabolic disturbance or the deposition of renal calculi.

ANSWER.—The question pertaining to "potential metabolic disturbances" suggests cholesterol metabolism. This whole subject is still in the realm of active research. If fat intake seems most important in this connection, one should recognize that milk is by no means a high-fat food (when it contains 3.9% fat by weight, giving 51.3% of the total calories). On this basis milk would not seem to be the first food to be eliminated to reduce fat intake. If atherosclerosis were known to exist or if blood cholesterol levels were unusually high, the use of milk reduced in fat might be considered. This choice, however, may be contraindicated when one considers the question pertaining to kidney stones. Some evidence has been reported relating renal calculi to vitamin A deficiency in animals. If there were any question of diabetes or other metabolic disturbance interfering with the formation of vitamin A from carotene, the 1,600 I. U. or more of preformed vitamin A obtained from a quart of whole milk would be a safeguard. So far as the possibility that the one quart plus other intake of milk would make calcium intakes so high as to raise question of supercalcification is concerned, apparently even doubling the normal level of calcium intake has no such effect in the normal individual. Again, only if the patient already had evidence of renal calculi or belonged to a family where the incidence of stones is high would there seem to be any reason to anticipate problems related to the levels of calcium intake which are suggested by the ingestion of even more than one quart of milk daily. Until further evidence is available, it would seem reasonable to permit this normal young man to continue to enjoy his quart or more of milk per day.

RESIDUAL IODIZED OIL IN THE BACK

To the Editor:—*A patient has complained of vague low back pains, essentially in the lumbar and sacroiliac areas, for the past year; for the past four weeks he has complained of areas of neuralgic pain over the skin of the right lower quadrant and at times the right thigh and right knee. The pain in the right thigh and right knee does not seem to follow the course of sciatic radiation. It is fleeting in character but may persist for hours; it is relieved to considerable extent by analgesics. Fifteen months ago a large intervertebral ruptured disk was removed between L-4 and L-5 to relieve severe root pain in the left ankle and the lateral aspect of the left foot. The disk was sequestrated, and after this surgery the root pain and numbness in the left foot were relieved. Yet, the vague lumbar aches and neuralgic pains over the right lower quadrant, right knee, and right thigh, anteromedian, persist. Recent x-rays reveal that "numerous small and large opaque droplets, presumably representing Pantopaque or Lipiodol, are present in the lower lumbar subarachnoid space; there is a suggestion of an operative defect in the region of the articular processes of L-4 and L-5 on the left side." Spinal fusion was not done as instability did not seem to be too marked. Could the residual iodized oil be responsible for the neuralgic picture and the vague low back pains? Should another attempt be made to remove these radiopaque mediums, even though the operator attempted to do so at the time of making the myelogram but was not successful?*

M.D., Florida.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—It is not believed that residual iodized oil is responsible for the vague aches and pains of which this patient complains. If the oil is broken up into small droplets, it would be impossible to remove it, even though the cauda equina were exposed surgically. Suggestions include rest, support, mild analgesics, heat, and any other conservative therapeutic measures, including encouragement, which are available. If symptoms become worse, further extrusion of disk material on the other side or at a higher level should be considered as a possible cause of complaints.

Answer.—The question of whether residual-iodized oil within the subarachnoid space causes irritation and symptoms has been debated pro and con for years and probably dates back to the first use of this substance. The literature contains a number of articles supporting the contention that it does cause symptoms. The fact that there is a paucity of statistics to support the other side of the argument is of no moment. Patients who do not have symptoms do not present themselves for study. There must be many thousands of patients going about their normal daily activities in the United States with varying amounts of these nonabsorbable oily substances within the subarachnoid space. It is rarely possible to remove every droplet of this oil after making a myelogram. Most of the patients who have this oil within the spinal canal do not realize that i is there. Extensive review of the literature has no been carried out, but this consultant is not aware o any series of cases in which the removal of residual oi as a sole treatment for symptoms arising in the spina canal and attributed to arachnoiditis has resulted i relief of symptoms.

If it can be determined by means of gravitation flow that the residual iodized oil in this patient mobile, there would seem to be no harm in attemptin its removal. However, previous to its removal it is sug gested that some oil be added and that myelography b repeated. A recent series of myelograms done im mediately after the removal of herniated disks hav indicated that the defects seen in the preoperativ myelograms persist postoperatively in some cases. Th work is not yet published. It is this consultant's opinio that, if it can be determined that the residual symp toms are arising from the fourth interval, fusion of th interval of the distraction type should be carried ou

ALCOHOL AND GLYCERYL TRINITRATE FOR MYOCARDIAL INFARCTION

To the Editor:—*Please comment on the alleged da ger in the use of glyceryl trinitrate (nitroglyceri and/or alcohol in a coronary attack.*

M.D., California.

Answer.—The expression, "in a coronary attack," i interpreted to mean the pain associated with acute myocardial infarction. As a rule, this attack of pain is severe, and the use of morphine is indicated to control the pain. The use of glyceryl trinitrate is indicated in attacks of pain caused by angina pectoris brought on by effort. Patients who have myocardial infarction often are in shock, and their blood pressure is low. Glyceryl trinitrate tends to lower the blood pressure. It usually is considered to be contraindicated, because of this factor, when myocardial infarction is present.

lcohol has no specific action which modifies the image after acute coronary arterial insufficiency. oreover, by the vasodilating action of alcohol, blood ressure is lowered and the insufficiency of the coro- ry circulation is further increased. Hence, on scien- fic grounds, there is no indication for the use of al- ohol in the presence of myocardial infarction.

E-TREATMENT OF SYPHILIS

O THE EDITOR:—*In 1942 a 42-year-old man had a history of a penile sore at the age of 22. Serologic examinations revealed 4+ Wassermann and Kolmer reactions, a clear spinal fluid with a cell count of 60 per cubic centimeter, a 4+ spinal fluid reaction, and a paretic type of colloidal gold curve. Between May and August of 1942 the patient was given a total of 39 Gm. of tryparsamide. Subsequent tests in 1946 included a spinal tap, with all tests negative, no colloidal gold curve, 2+ Wassermann and Mazzini reactions, a doubtfully positive Kolmer reaction, and a doubtful 1+ Kahn reaction. In May, 1947, the Wassermann and Mazzini reactions were 4+; the Kolmer reaction was 2+. In August, 1947, the Mazzini reaction was 4+, and the Kolmer reaction was 4+. In 1954 the patient came in complaining of dizziness. Further tests showed a doubtful 2+ Mazzini reaction and a weakly reactive Venereal Disease Research Laboratory test. The patient was referred to a neurologist who felt that he should have a repeat spinal tap and that his then present condition was a manifestation of syphilis of the central nervous system. The patient, however, refused to have another spinal tap because of a severe headache after his last one. This year the patient came in for an insurance examination. Blood serologic tests revealed a weakly reactive Venereal Disease Research Laboratory test and a nonreactive Kolmer test. A spinal tap revealed a clear fluid with a total protein content of 32 mg. per 100 cc. Venereal Disease Research Laboratory and Kolmer tests were both nonreactive. At the suggestion of the state laboratory a Treponema pallidum immobilization test was done on March 30, 1957, and was reported by the Communicable Disease Center, Venereal Disease Research Laboratory, Chamblee, Ga., as follows: Treponema immobilization test, reactive; Treponema immobilization complement-fixation test, reactive. The only positive sign of syphilis is a slightly larger right pupil, but both pupils react to light and accommodation. The patient is completely asymptomatic and apparently has had no treatment since the original treatment with tryparsamide in 1942. How should he be treated?*

E. G. Bourns, M.D., Westfield, N. J.

ANSWER.—The patient in question should now be eated with 6 to 10 million units of a repository peni- illin product, e. g., procaine penicillin-in-oil or Bicil- n, given in 10 to 16 injections two or three times a eek. This advice is given not because of the persistent blood serologic tests or of the positive Treponema immobilization and Treponema immobilization complement-fixation tests in blood and/or spinal fluid; these are of relatively little importance. It is also given in spite of the fact that the most recent examinations of the spinal fluid (cell count not stated) are normal as to total protein content and serologic tests.

The advice is given because the inquirer indicates that the only antisyphilitic treatment which the patient has had for neurosyphilis (presumably asymptomatic in 1942) was 39 Gm. of tryparsamide. This is not enough treatment to provide him with much security for the future. The penicillin treatment advised may be regarded as prophylactic and should offer him about 95% security for the future.

DRYNESS OF MOUTH AND TONGUE

TO THE EDITOR:—*A patient, aged 70 years, has had an absolute dryness of the mouth and tongue for the last two years. Examination is negative except for moderate obesity and associated hypertension, which has been corrected, and mild conjunctivitis. The salivary glands are not unusual. Complete blood cell count, urinalysis, nonprotein nitrogen level, blood cholesterol level, and blood electrolyte concentrations are all within normal limits. Basal metabolic rate and radioiodine (I^{131}) uptake are normal. The patient is not a mouth breather. He states, however, that there are occasional periods in which the mucous membrane has a little moisture. What can be done to help this patient?*

J. Will Fleming Jr., M.D., Moberly, Mo.

This inquiry has been referred to two consultants, whose respective replies follow.—ED.

ANSWER.—It is possible, and perhaps likely, that the medication used for control of hypertension is responsible for the dryness of the mouth and tongue. This is a common complaint of patients who are receiving Rauwolfia-like preparations. Dry mucous membrane in the mouth is sometimes seen in association with the pharyngitis sicca which usually accompanies both true atrophic rhinitis and the atrophic type of chronic rhinitis often present in elderly people. The latter may evidence endocrine changes after the male or female climacteric. Checking hypertensive drugs used for this patient and the administration of potassium iodide, 0.3 Gm. three or four times daily, together with an adequate fluid intake, might help this patient.

ANSWER.—The condition described would seem to meet the requirements for classification as Sjögren's syndrome. According to Dorland, this syndrome is characterized by "dryness of all mucous membranes, resulting from deficient secretion of the glands, particularly the lacrimal and salivary glands, those of the upper respiratory tract, the sweat glands, and the glands of the stomach." The syndrome usually appears in elderly people. There is no known treatment which has a general effect. Locally, artificial tears can be used in the eye whenever the symptoms require. The most satisfactory of the artificial tears is Isopto-Alkaline Ophthalmic Solution. Cortisone applied locally to the eye has an ameliorating effect for some patients who have this syndrome, but when it is taken by mouth it is of no value.

STERILIZATION OF SHOES

To the Editor:—*Is there a method of sterilization of rental shoes with skates which the owner of a roller-skating rink might use to cut down the incidence of "athlete's foot"?* *M.D., Pennsylvania.*

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—There is no satisfactory method of sterilization of shoes. Strong fungicides, such as formaldehyde, even if effective would cause in some individuals an irritation and sensitization. Furthermore, they would in time damage the shoes. It is therefore recommended that to keep the feet and shoes dry a bland dusting powder composed of the following be used: bismuth subgallate, 1½ dr. (5.8 Gm.); zinc sterate, 3 dr. (11.6 Gm.); amylum, 4 dr. (15.5 Gm.); and talcum, 4 oz. (124.4 Gm.). This powder should be sprinkled in the shoes before and after they are used.

Answer.—In "Diseases of the Skin" by Ormsby and Montgomery (ed. 8, Philadelphia, Lea & Febiger, 1954), there is the following passage on sterilization of shoes:

> Cleanse the shoes of extraneous debris with mild soap and water; dry with a cloth; place a wad of cotton in each shoe and spread out to form an insole; pour onto this insole (in each shoe) 1 teaspoonful of solution of formaldehyde (U.S.P.) diluted in 1:10; put shoes in paper box; close and wrap in paper and leave shoes in box at least six hours; remove shoes from box, remove and discard cotton; place them in air for twenty-four hours; apply saddle soap to all parts of shoes, and allow to dry; polish. The formaldehyde can be neutralized by placing the shoes in a 0.5 per cent solution of sodium bisulphite for two minutes.

For a business organization, carrying out the above would be a very difficult assignment. Finding competent, conscientious help would be an insurmountable difficulty. There is also to be taken into consideration the effect of formaldehyde on leather, and the use of aqueous solutions on leather would be harmful as well as dangerous owing to the use of metal and leather. It would probably be better to impregnate socks in a fungistatic or fungicidal solution, dry same, and supply each customer with same, compelling use over the customer's own socks. The best idea would be to compel each person to supply his own shoes with skates. At the present time, when parental monetary allowances have assumed such fantastic proportions or odd jobs offer such rich monetary rewards, this would not be a prohibitive expense especially when a contagious disease so difficult to cure is involved.

ANTICOAGULANT THERAPY

To the Editor:—*A patient was admitted to the h pital with a questionable diagnosis of a b tumor. An angiogram was done and then a ven ulogram, after which a diagnosis of a vasc thrombosis (middle cerebral) was made. Admi tration of Dicumarol was ordered, with d prothrombin time tests. The patient has been r ceiving this drug for two weeks prior to writing. H is about to be discharged from the hospital, a he and his family have been told by consultants t he will be all right. He is to continue the Dicuma therapy at home, with a biweekly prothrombin ti test, under his physician's supervision. The lite ture states that Dicumarol is a dangerous drug a that it has no effect on an already formed thromb its effect being simply to prevent the formation further clots. Can the drug be given for an indefi period of time?* *M.D., Rhode Island.*

Answer.—Dicumarol may be given indefinitely, provided that fairly frequent prothrombin determinatio are made. The patient must have had his Dicumar medication well established during his hospital sta and therefore a continuation of the present dosag with twice-weekly prothrombin determinations, wou be quite safe. Dicumarol is a dangerous drug unle properly supervised.

The original damage from the cerebral thrombos is still there. The purpose of the Dicumarol therap is to minimize the dangers of repeated recurrences c clotting. It is presumed that blood cholesterol dete minations have been made, for in many cases of cerebral thrombosis these levels are apt to be elevated. I such is the case, the patient should have a relatively low fat intake, in addition to his medication with Dicumarol. Both of these methods of treatment are precautionary only and do not correct the original damag

NYLON SUTURE MATERIAL

To the Editor:—*Ordinary monofilament nylon fishin line has been used as a suture material for years wit excellent results. It is now desired to use nylon ski sutures (not buried) and to sterilize this material i suitable lengths from bulk spools. Initial experiments have indicated no change in length or breaking strength after routine steam autoclaving. Th material most available is ordinary fishing line of th type intended primarily for spinning reels. Is thi material likely to have been treated with any chemical which might cause unfavorable tissue reactio or interfere in some other way with its use as a suture material? Also, what would be the recommended method of sterilization if autoclaving is deemed undesirable?*

Wayne E. Armstrong, M.D., Gwinn, Mich.

Answer.—While one can use ordinary monofilamen nylon fishing line as suture material for skin closure it is much preferred that nylon sutures prepared b eputable manufacturer of suture materials be util- d. The manufacturers of fishing lines may subject nylon to treatment with various chemicals for the rpose of plasticizing and waterproofing the lines. estuffs of unknown origin may be utilized to color nylon fishing lines. Such treatments may vary m manufacturer to manufacturer. Suture manufac- ers who label their nylon sutures as "U. S. P." oducts are required to meet the specifications for nabsorbable surgical sutures as outlined in the Phar- acopeia of the United States U. S. P. XV. If a coal-tar rivative dyestuff is utilized to color a nonabsorbable ture, the manufacturer of that suture is required to ilize a dyestuff that is certified by the United States ood and Drug Administration. Nylon can be steril- ed satisfactorily by autoclaving under standard con- tions.

REATMENT FOR LEPTOSPIRAL DISEASES

o THE EDITOR:—*What is the current treatment for leptospirosis icterohaemorrhagica (Weil's disease) and leptospirosis canicola (Stuttgart's disease)? Are the spirochetes sensitive to any known antibiotic, and, if so, what is the recommended dosage?*

M.D., Montana.

ANSWER.—There is no really satisfactory treatment or these two diseases. Penicillin, Aureomycin, Terra- nycin, and streptomycin are all moderately effective n vitro, but in vivo their effect is not clear-cut. It is robable that these antibiotics are reasonably effective f given before the onset of symptoms or during the irst few days of illness. Terramycin and streptomycin re probably the best. The former should be given n doses of 2 to 3 Gm. and the latter in doses of 2 Gm. a day. Treatment after the infection has become established is of doubtful, if any, benefit.

ECTOPIC GASTRIC MUCOSA

TO THE EDITOR:—*Please supply information concerning ectopic gastric mucosa. Could this be the cause of a tumor, and what is its clinical significance?*

William G. Abel, M.D., East Hampton, N. Y.

ANSWER.—The presence of epithelial elements of the gastrointestinal tract within the wall of the stomach is not rare. These are developmental anomalies and not true neoplasms in the sense of being uncontrolled new growths of tissue. Nevertheless, because of their gross appearance they are frequently included in classifications of benign tumors of the stomach. Terms applied to these lesions include "heterotopic or ectopic pancreatic tissue," "adenomatous tumors," and "adenomyomas." The foci of ectopic tissue, which are usually solitary, occur anywhere in the stomach and are most common in the submucosa of the pyloric portion. Grossly, these lesions may result in projecting masses or diffuse thickening of the gastric wall. Some are cystic, and occasionally a duct opening into the lumen of the stomach may be present and even demonstrated by x-ray examination. The overlying gastric mucosa, which is usually intact, may occasionally be ulcerated. Microscopically, pancreatic tissue, the duodenal glands known as Brunner's glands, and glands like those of the stomach or colon may be present. Pancreatic tissue, with acini and ducts and without islets of Langerhans, is most frequent. When the ectopic tissue is in the muscularis, proliferation of muscle about the epithelial elements, as in adenomyomas (endometriosis) of the uterus, is common. Clinical manifestations include epigastric pain, pyloric obstruction, and occasionally hemorrhage. A few reported cases of carcinoma have been thought to originate in such heterotopic tissue.

OCCUPATIONAL DISEASE IN THE TANNING INDUSTRY

TO THE EDITOR:—*Kindly supply information regarding morbidity in tannery workers who are exposed to potent chemicals.*

T. J. Kern, M.D., Hartford, Wis.

ANSWER.—Up to a few decades ago, the tanning industries were a prolific source of occupational diseases as to both number and variety. In 1925, Minster published a paper on hazards in the tanning industry (*J. Indust. Hyg.* 7:299, 1925). These hazards involved both bacterial and chemical exposures. At that time the outstanding opportunities for damage centered about the chromates, benzene, hydrogen sulfide from the decomposition of organic matters, and divers tannins, both natural and synthetic, the former embracing several exotic woods, such as quebracho. There are several forms of tanning which are almost distinct enterprises. These include the tanning of sole leather, shoe leather, upholstery leather (the latter two forms involving coating operations), and, finally, special and fine skin leathers, such as those used for gloves. Synthetic leathers and substitutes for leather have enormously modified tannery operations. At the present time the exposures in the tannery industries have so well been brought under control that the incidence of occupational disease is low. The total number of diseases scarcely warrants group compilation or statistical analysis. Dermatitis remains the chief threat, with the chromates and tannins constituting the major offenders.

PSORIASIS AND GARLIC

TO THE EDITOR:—*Is there any clinical evidence that garlic extract is of any value in the treatment of psoriasis when applied topically?* *M.D., Maine.*

ANSWER.—Psoriasis is a therapeutically erratic disorder for which practically everything has been recommended for treatment. Garlic has been suggested for the treatment of a long list of entities. It was inevitable that the two should meet in the treatment of psoriasis. Garlic itself is not only unpleasant to the olfactory organ but is irritating to the skin when applied locally. Personal experience with the topical application of garlic has been confined to a group of lepers isolated in a separate cottage. Ambulatory psoriatics would not be pleased with the cutaneous burns produced by such applications or by the social ostracism that would greet one with garlic on the skin. Garlic extract tablets, such as those used in the treatment of hypertension, and extracts of this plant (Allium sativum) are characterized by the odor that has become diagnostic of garlic in the vicinity. Before accepting this agent as an effective treatment for psoriasis, a great deal of work is necessary to establish its efficacy in this spontaneously remittent disease, to mask its odor, and to eliminate those factors that burn the skin.

TREATMENT AFTER RADICAL MASTECTOMY

To the Editor:—*A 50-year-old woman, four years past the menopause, noted a lump in the right breast. Examination disclosed a mass about 4 in. in diameter. A frozen section showed it to be malignant, and a radical resection was performed. Pathological report showed 14 axillary nodes to be invaded by metastases. The tumor was adenocarcinoma. There is no other spread. Should this patient be subjected to deep x-ray therapy or to an ovariectomy or hormonal therapy as a precautionary measure?*

M.D., Massachusetts.

Answer.—There is a great difference of opinion in regard to this query. The consensus would be that this patient should have x-ray therapy to the supraclavicular and internal mammary areas on the side of the lesion and should not have an ovariectomy or hormonal therapy until positive indication arises.

ENDOCRINE THERAPY AFTER REMOVAL OF MALIGNANCY

To the Editor:—*A woman, aged 46 years, had a radical mastectomy for a malignancy of the breast about two years ago but no irradiation. The lymph nodes dissected from the axilla were normal, and there have been no signs of regrowth or metastasis to date. Would there be any contraindications to using testosterone for relief of severe menopausal symptoms?* *Leo. J. Greenberg, M.D., Chicago.*

Answer.—At the age of 46, this patient probably has ovarian failure from organic senescence, with lowered estrogen activity and perhaps some elevation of 17-ketosteroids. She has "severe menopausal symptoms," which probably means "flushes" and vasomotor instability. There is still discussion as to the effectiveness of sex hormone therapy in the relief of such symptoms. There apparently are no metastases and no evidence that the tumor was "estrogen dependent." As is known, there is no direct evidence that estrogens are carcinogenic agents in the human. However, most physicians would be unhappy with the addition of any sex steroid in a patient who has no evidence of recurrence or metastasis of breast cancer two years after operation. Psychotherapy, tranquilizing drugs or barbiturates suggest themselves as preferable alternates to either testosterone or estrogen therapy in relieving what is a temporary inconvenience.

ENURESIS

To the Editor:—*The superintendent of a boys' home has asked me for information concerning a group of bedwetters, aged 14, 15, 16, and even 18 years. The boys have been given ¾ grain (50 mg.) of ephedrine sulfate each night before retiring and have had good results while the drug has been administered; some of them have been cured. Is there any danger in the prolonged use of ephedrine sulfate in these youths as far as cerebral stimulation or other complications are concerned?*

John F. Raycroft, M.D., Brooklyn, N.Y.

Answer.—This consultant cannot sympathize with drug treatment of enuresis as a general procedure, because it is often merely a placebo, and the condition evades diagnosis. Enuresis is most frequently a psychiatric symptom in a multisymptomatic psychiatric disorder. The superintendent of the home should obtain psychiatric service for the youths. Enuresis is a sign of anxiety and psychopathological immaturity of ego development.

GENERALIZED ATOPIC DERMATITIS

To the Editor:—*The answers to the query concerning the management of atopic dermatitis in* The Journal *for March 30, 1957, page 1197, demonstrate the need for more complete understanding of this "strange disease." Atopic dermatitis, or neurodermatitis disseminata (atopic eczema), in all but very young infants does not appear to be a manifestation of specific allergy, with extremely rare exceptions. Elimination diets, cutaneous testing, and desensitization lend little to the management of this disease; in fact, they are generally useless.*

The etiological factors in atopic dermatitis and in duodenal ulcer, ulcerative colitis, migraine, and some cases of asthma and rheumatoid arthritis appear to be similar, if not identical. It is a stress complex, the skin being the organ which reflects the emotional tone of the individual, although other organs or systems may also be affected simultaneously or alternately. Emotional factors dominate as the trigger mechanism in the exacerbations of the disease in those persons who constitutionally react cutaneously to stress. The type of emotional disturbance, of course, varies, although infantile attitudes, repressed aggressions, fears of failure, and guilt complexes seem to be common. Psychiatric management, especially in groups of such individuals, appears to be useful as adjuvant therapy; individual therapy generally has not been as successful.

Hospitalization or drastic curtailment of normal activities is probably not desirable, unless there are specific indications for such, as in the case of marked *secondary infection or other important complications. Adjustment to the normal stresses of everyday life is a necessity, and the elimination of these stresses for periods of time, although it generally will give relief, does not make for the development of a satisfactory adjustment. Compulsive activity is better controlled by insight than by enforced stoppage; activity is actually a means toward remission.*

The use of steroids, locally and/or parenterally, is of considerable aid in the control of exacerbations and for maintenance of severe conditions. If the patient is under careful observation and the smallest doses are used for control, there seems to be little attendant danger of undesirable side-effects in relation to the atopic dermatitis. It is important that dosage be gradually diminished. Rarely, tranquilizers and sedatives have demonstrable desirable effects. Indicated local measures aid in the healing of severely affected areas; antibiotics are useful in the control of secondary infectious processes.

A fuller understanding of this common distressing disease, as well as its relation to other dermatological and systemic diseases, is greatly to be desired. A research foundation for the study of atopic dermatitis should be organized and endowed to this end.

W. F. Edmundson, M.D.
W. B. Guy, M.D.
7026 Jenkins Arcade
Pittsburgh 22.

The above comment was referred to one of the conultants who answered the original query, and his eply follows.—Ed.

o THE EDITOR:—*The comment is a well-considered presentation of the physicians' concept of atopic dermatitis. One must agree that a fuller understanding of atopic dermatitis, as well as the establishment of a special research project or foundation for its study, is to be desired. Such efforts have been made in the past but unfortunately did not meet with success.*

As yet there is great confusion and disagreement about the etiology of atopic dermatitis. Recent articles by Gans (Tr. St. John's Hosp. Dermat. Soc., *no. 37, p. 1, 1956) and Baer* (Excerpta Med. *[sec. 13]* 11:*47, 1957) well present the conflict of opinion, and so does the recent controversy on the role of allergic factors in atopic dermatitis in the correspondence and editorial sections of the* Journal of Allergy (J. Allergy *27:293, 480, and 483, 1956). The Pennsylvania physicians add their concept to the controversy.*

Atopic dermatitis always has been a mysterious disease which has given rise to much speculation. The French authors who first clearly set apart atopic dermatitis as lichen simplex chronicus (Vidal), neurodermatitis (Brocq), and prurigo diathesique (Besnier) some 70 years ago proposed "autointoxication" and nervous elements as etiological factors. In the 1920's and 1930's allergy became the fashion of the day, to be followed by the concepts of psychosomatic disorders; now it is the stress complex, which according to Selye is the common denominator of disease. Most of these theories have been proposed by men of great knowledge and insight into the problems. Yet there is a tremendous difference of opinion. Obviously a simple hypothesis will not do. One may well accept stress as a mediator of various underlying factors, such as allergic, emotional, infectious, and endocrine, in persons endowed with a peculiar physical and psychological make-up.

There are some statements in the comment of the Pennsylvania physicians which should not go unchallenged, such as the fact that allergic management is generally useless. Allergy plays a great role in some cases of atopic dermatitis at every age, although it is only one factor in the picture; in infantile eczema it is frequently of decisive importance. As the patient grows older, other factors, especially emotional, become more important. Hospitalization in severe cases is of great help so as to give the patient rest and allow a thorough allergic and psychiatric investigation to be made away from the physical and emotional home environment. It is at times the only means which demonstrates to the patient that something can be done for him.

Management of atopic dermatitis is not necessarily dependent on the administration of this or that medicament or the application of this or that theory. It depends much more on the physician, who has an interest in the disease and takes the time to give his patient care and understanding, and on the patient, who is confident that his physician is willing and able to help him.

MONARTICULAR ARTHRITIS AFTER POLIOMYELITIS VACCINATION

To THE EDITOR:—*Apropos the answer to a query in* THE JOURNAL *for June 29, 1957, page 1035, I should like to call attention to the fact that monarticular arthritis can occur after poliomyelitis vaccination and that this can be evidence of an acute gouty attack. I make this statement because a 35-year-old man, who had never suffered previously from an acute attack of gout, had three such attacks during a seven-month period last year, each within 12 hours after his "polio shot." The response to the administration of colchicine and the clinical picture were typical of gout. I feel certain that other physicians will have a similar experience as more of the poliomyelitis vaccine is used on adults. It is not unusual for other substances, such as liver extract, to precipitate a gouty attack. I should suspect that the high nucleoprotein content of killed viruses might account for such a diathesis.*

435 N. Roxbury Dr.
Beverly Hills, Calif.

SALTING FRESH MEAT TO REMOVE BLOOD

To the Editor:—*Reference is made to the query concerning the salting of meat and its relation to a salt-free diet, which appears in* The Journal *for July 6, 1957, page 1174. In the correspondence section of* The Journal *for Dec. 19, 1953, page 1472, data provided indicate that meat processed according to Jewish dietary law has its sodium content increased remarkably. However, if the salting is not excessive, cooking takes out practically all the added sodium. Additional comments of interest with respect to salted meat and its treatment by boiling, broiling, frying, or roasting have been made in the correspondence section of* The Journal *for March 27, 1954, page 1114.*

George X. Trimble, M.D.
Medical Director, St. Elizabeth Hospital
1044 Belmont Ave.
Youngstown 4, Ohio.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*It has been almost four years since the publication of the letter in* The Journal *about salt-poor diet and Jewish dietary laws, and some of the information could well bear repeating. Dr. Bruno Kisch has given some data indicating that the processing of raw meat according to Jewish dietary law increases the sodium content remarkably. He found that an average piece of beef containing 55 mg. of sodium per 100 Gm. before being salted contained 234 mg. per 100 Gm. after being salted according to the usual Jewish dietary laws. It was shown that, if salting is not excessive, cooking takes out practically all the added sodium. The soaking of salted meat in cold or warm water before cooking removes the salt sprinkled on the surface quite well, especially if the amount of salt is not excessive. It seems that, if treated meat is to be used in a salt-poor diet, the cook should use a minimum of salt, allow the meat to stand only for the religiously permissible period of time, and cook the meat in a generous amount of fluid and throw away the broth.*

PROLONGED STEROID TREATMENT OF ASTHMA

To the Editor:—*A part of the answer by the first consultant to the query regarding prolonged steroid treatment of asthma in* The Journal *for March 9, 1957, page 908, is, in my experience, wrong. I refer to the sentence wherein the consultant deprecates skin testing for food allergy in children.*

If there is any age group in which food-allergy skin tests closely approach the clinical findings, it is in the case of children. In this group such foods as nuts, fish, eggs, milk, and cereals frequently alert the experienced allergist to one or more of the causes of the allergy, since the younger the patient the greater is the possibility of food allergy being a factor, and its detection is expedited by skin tests expertly utilized.

In this connection the difficulties in the past as well as at the present time stem from certain factors. 1. The technique is poor; a control must be used with each series of tests so as to evaluate hypersensitive reactions, which are really negative but are oftentimes called positive, with consequently incorrect interpretation and clinical result. 2. Skin testing is not a laboratory procedure but requires the personal services of a skilled allergist, both from a safety-to-life standpoint when intracutaneous tests are performed and for the expert evaluation of the findings (correspondence section, J. A. M. A. 152:355 *[May 23] 1953).*

David L. Engelsher, M.D.
178 E. Mount Eden Ave.
New York 57.

PEDIATRIC DOSAGE OF STEROIDS

To the Editor:—*This is with reference to a statement of the consultant in his answer to a query concerning pediatric dosage of steroids which appeared in* The Journal *for July 6, 1957, page 1174.*

The consultant stated: "Prolonged use of cortisone will suppress growth of children when used in doses of 45 mg. or less per square meter of body surface daily." I believe the phrase "or less" should really read "or more," inasmuch as a report on the effects of cortisone therapy on the growth of children (Blodgett and others: New England J. Med. 254:636, *1956), from which possibly the consultant derived his information, states: "A minimum of 45 mg. per square meter [of body-surface area] per day was required to reduce the growth rate of endocrine-normal children."*

*This statement bears out some observations by Hill on this subject (*New England J. Med. 253:821 *1955), pointing to the fact that, in a series of allergic children whom he was treating with cortisone over prolonged periods of time, no evidence of retardation of growth could be found sufficient to warrant withholding cortisone when it was needed.*

George X. Trimble, M.D.
St. Elizabeth Hospital
1044 Belmont Ave.
Youngstown 4, Ohio.

The above comment was referred to the consultant who answered the original query, and his reply follows.—Ed.

To the Editor:—*The physician is correct. The statement should read: "Prolonged use of cortisone may suppress growth of children when used in doses of 45 mg. or more per square meter of body surface daily."*

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

Most Major Health Bills Await Action Next Year
National Commission Proposed on Influenza
Social Security 'Medicare' Plan Suggested
UMW Reports on Welfare and Retirement Fund

FEW BILLS ENACTED IN FIRST SESSION

No surprises developed in medical legislation during the closing days of the first session of the 85th Congress. As a consequence, only three bills in this field were signed by the President in the last week of the session.

One again makes federal inspection of poultry mandatory, with the processors paying all costs. The Department of Agriculture will be in charge, with the secretary deciding which of several divisions of the department will do the actual work.

In addition to assuring wholesomeness of poultry and poultry products put on the market, the new law aims at maintaining sanitary facilities and practices at slaughterhouses and processing plants and requiring correct and informative labeling.

The other two bills enacted in the final week amend vocational rehabilitation programs. One authorizes continuation of old grants (as long as left-over money remains) to expand and improve state plans, and the other permits three-year training grants in vocational rehabilitation and physical medicine, instead of the former two-year limit.

Nor were there many bills enacted earlier in the year. One important one amended the selective service act to limit special obligation to physicians through age 35 who have received deferments. Under it doctors may be called because of their professional status, rather than by the age groups which govern call-up of other men.

In another amendment, Congress changed a law enacted only last year that set up a new program of federal assistance for the medical care of public assistance recipients. Early this year several states discovered that unless some changes were made they would not be able to take advantage of the full federal offer, and in at least one case the state would be getting less federal aid than previously. The law corrected this situation.

In its effort to improve the medical care of Indians, the Public Health Service, which took over this responsibility in 1955, endorsed a bill to have the U. S. make grants for construction and equipment of hospitals to be used by Indians and non-Indians alike. It was explained that Hill-Burton grants were not always the answer, because many communities on or near reservations operate on such a low economic scale that they are unable to raise the sponsor's share needed to qualify for Hill-Burton loans. This bill passed late in the session.

Aside from these measures, very few health or medical bills even made their way out of committees. The National Medical Foundation for Eye Care, supported by the American Medical Association, opposed a section of the bill that would have given optometrists the same pay and status as physicians, but neither organization opposed the pay increase section of the bill. The bill was reported out of the House Veterans Affairs Committee, but there was no further action as the Rules Committee was not asked to schedule the bill for a floor vote.

NATIONAL COMMISSION ON INFLUENZA PROPOSED

State and Territorial Health Officers want Surgeon General Burney to appoint a national commission on influenza and to recommend a specific list of priorities to govern use of the vaccine. Dr. Burney is studying the possibility of appointing a research commission, and already has made informal suggestions for priorities.

The two recommendations were among a number adopted by the State and Territorial Health Officers at a two-day meeting in Washington, D. C., called by the surgeon general to acquaint the health officers with developments to date in the Asian influenza situation and enlist their full support in the campaign that is being organized to minimize the effects of epidemics.

Participating in the meeting also were Dr. Harold Lueth, Chairman of the A. M. A. Special Committee on Influenza, and his committee members, who for several months have been supplying physicians with detailed information on Asian influenza and encouraging them to take the lead in setting up community committees or councils to make effective use of health facilities and personnel.

The commission suggested by the health officers would be concerned mainly with the scientific aspects—keeping track of the changes if any in the virus and its effect on humans. It would consider "not only the urgent problems in connection with the current epidemic but also long-range problems associated with the behavior of the Asian and other strains of influenza virus in the population during the next decade."

Action taken earlier by the Public Health Service to start the voluntary allocation of vaccine by states was endorsed by the health officers, who called on the PHS also to recommend to civilian physicians that they observe the following priorities in vaccinations: first, to those whose services are necessary to maintain health of the community; second, to those whose employment is necessary to maintain other basic services; and third, to persons with tuberculosis and others who constitute a special health risk.

However, it was proposed that local committees, not the PHS or state health departments, designate the classes of persons to be regarded as performing "basic community service," and therefore entitled to early vaccinations.

Regarding laboratory diagnosis to establish presence of Asian influenza, the health officers state:

"The important laboratory work lies in the substantiation of an epidemic and is of little value to the individual patient. In the identification of an outbreak, throat washings and paired sera should be submitted from at least twelve clinical cases, accompanying the specimens should be a clinical abstract and data on how specimens were taken. The specimens should be gathered in the face of an explosive outbreak of upper respiratory illness within the first three days of illness and submitted through the state health authority.

"Technical information on securing and preparing specimens together with restrictions should be disseminated through state channels. Local health authorities should participate in the evaluation of an epidemic situation in accordance with existing policy."

It was also suggested that "several states" be selected to gather intelligence rapidly on occurrence of pneumonia, often a complication of influenza.

It was proposed that weekly state reports to the PHS include but not be limited to symptoms and etiology, complications and mortality, and age groups involved.

SENATOR NEUBERGER FAVORS "MEDICARE" UNDER SOCIAL SECURITY

Senator Neuberger (D., Ore.) believes the time has come to set up a system of government-paid hospitalization for old people covered by social security, modeled as closely as possible to the Dependent Medical Care program that for more than nine months has been operated by the Defense Department.

Although the senator has not worked out a draft of his bill yet, he believes a 2% increase in social security taxes—1% each on workers and employers—would meet the hospitalization costs.

In addition to free hospitalization, the Neuberger plan includes payment for in-hospital surgical costs. Unlike the military–Public Health Service Medicare program, which bills the patients for the first $25 in civilian facilities or $1.75 per day in military, the senator's plan would make no charge against patients.

The Neuberger idea is to make use of Blue Cross or other nonprofit groups, using arrangements similar to those now in effect in many states under Medicare.

Senator Neuberger outlined his views when talking before the national convention of the Brotherhood of Eagles, where he also suggested that permissible outside earnings for those receiving Social Security retirement benefits be increased from the present $1,200 to $2,400 per year. Later he said a great deal of interest was shown by the Eagles in his hospitalization-for-the-aged plan.

UMW FUND HOSPITALIZES 63,779

The United Mine Workers' Welfare and Retirement Fund report shows that during the last fiscal year (ending last June 30), the fund paid $59,500,000 for 1,631,144 hospital days' care for 93,679 sick or disabled miners. The hospitalized cases entailed 1,556,111 visits by doctors, and in addition 885,944 outpatients clinic and office consultations by specialists are noted.

Over the 12 months, the fund's unexpected balance increased by more than 10%, from $130,100,000 to $145,300,000. Revenue for the year—from royalties on coal mined—totaled 157 million dollars, and expenditures $141,900,000.

In discussing the medical care program, the report says in part:

"In compliance with the basic obligation of the trust fund to maintain complete and final control over all fund benefit programs and funds expenditures for them, these regulations, which have continued in effect throughout this fiscal year, require for eligible beneficiaries a high quality of hospital and medical services at a reasonable cost to the fund."

Pension payments to 63,009 retired miners totaling 75 million dollars made up the biggest single expense during the year.

AEC MAKES ITS 100,000th SHIPMENT OF RADIOISOTOPES

In a little over 11 years, the Atomic Energy Commission has shipped 100,000 packages of radioisotopes from its Oak Ridge National Laboratory as part of AEC's program in developing the peacetime uses of atomic energy. The first shipment was made Aug. 2, 1946, to a St. Louis skin and cancer clinic. The 100,000th shipment went out Aug. 26 of this year to the University of Iowa, also for use in medical research.

AEC said more than 4,000 organizations have been licensed to use radioisotopes, while many others have received small quantities of radioactive material under general license.

"There has been a rapid increase in the quantities of radioisotipes per shipment in recent years," an AEC announcement said. "This is because of the increased number of shipments to commercial suppliers which buy bulk quantities of radioisotopes in single shipments from Oak Ridge. These are then processed into radioactive drugs, chemical compounds, radiation sources, and resold in thousands of shipments each month to licensed users."

HYPOTHYROIDISM

Arnold S. Jackson, M.D., Madison, Wis.

Thirty-seven years' experience in diagnosing and treating thousands of patients who have hypothyroidism has illustrated to the author that this chronic affliction not only occurs frequently in the Middle West but, more unfortunately, often goes unrecognized. The primary reason for overlooking hypothyroidism is the placing of too much reliance on a single metabolic test. Such a test rarely registers lower than it should, in contrast to frequent false-high readings. Equally important as the metabolic test is symptomatology; one of the most frequent complaints, seldom mentioned in the literature, is that of headache. In treating hypothyroidism the potency of various thyroid preparations must be given as much consideration as the dosage, for the successful results can depend as much on the use of strictly fresh tablets as on the administration of them.

Hypothyroidism is the most frequent chronic affliction and at the same time the most often overlooked condition affecting persons residing in the Middle West. This statement based upon an experience of 37 years in diagnosing d treating thousands of these cases seen at the ayo and Jackson clinics.

In countries whose civilization is many centuries d, as in Switzerland and in India where goiter has een prevalent for hundreds of years, hypothyroidism prevalent, as is cretinism, the end-result of goiter. he last survey made of cretinism in the United States as made by me in 1934, and this study showed a articularly high incidence of this condition in Wisonsin and other Midwestern states. Hypothyroidism prevalent in areas where for many generations ersons afflicted with goiter have resided. As a conequence, decreasing numbers of normal thyroid lands are found in the descendants. Such a condion has occurred in the great goiter belt that stretches ross our country from Boston to Seattle and roughly orth of the Mason-Dixon line. Just as the water and il of this area are deficient in iodine, goiter and ypothyroidism are prevalent, and here the highest cidence of cretinism may be found. So the pattern the same as in the older countries of the world.

Errors in Diagnosis

What is the reason that so many cases of hypothyidism go unrecognized? Frequently too much relice is placed in the report of a single metabolic st. Even when an initial test is made with a reliable achine by an accurate technician it may be incorrect if the patient is nervous or apprehensive and breathes rapidly. A report of perhaps +10% is registered for one that actually should read −15%. So the doctor assures the patient that the test is normal and that there is nothing wrong with the thyroid gland. More often the test is reported much higher, and then the physician is led to make the mistake of feeling that his patient is hyperthyroid instead of hypothyroid. In my files are records of 228 cases of this nature, in which metabolic tests were reported as high as 90% in persons whose thyroid glands were normal. In all these cases thyroidectomy had been advised largely on the basis of these false metabolic tests. Thus, even

Summary

After a 37-year study of hypothyroidism in the Midwest, I consider this condition to be the most frequent and most overlooked chronic disease in this area.

Nervousness and apprehension in a patient greatly affect the results of the basal metabolic test, and false-high readings occur frequently. The importance of repeating the metabolic test and of getting a thorough clinical history and physical examination of the patient is shown by the fact that in my files are 228 cases in which metabolic tests were reported as high as +90% in persons with normal glands.

Symptomatology is of prime importance. A symptom of hypothyroidism not mentioned often in the literature is headache. The most frequent cause of daily headache is hypothyroidism, and treatment of th hypothyroid condition often gives dramatic relief.

Some thyroid preparations are not reliable; no should be dispensed after three months, and occasio ally a patient may require a fresh supply at short intervals. Doses smaller than 1 grain (60 mg.) a d are rarely of value. I give 1 grain a day to youn children and to adults with a mild hypothyroid condition. Eighty per cent of my patients receive 2 grain (0.12 Gm.); no ill-effects have been noted from thi dosage.

SODIUM LIOTHYRONINE IN METABOLIC INSUFFICIENCY SYNDROME AND ASSOCIATED DISORDERS

PRELIMINARY REPORT

Joseph H. Morton, M.D., New York

The syndrome of metabolic insufficiency differs from hypothyroidism in that it occurs in persons whose thyroid gland function appears to be normal. Patients with this disorder do not respond to even large doses of desiccated thyroid. Some of the clinical manifestations of metabolic insufficiency, relieved by L-triiodothyronine, are chronic fatigue, dry hair, dry skin, irritability, and emotional instability. The response to L-triiodothyronine suggests that daily stress created by demands on metabolically insufficient patients can cause nervous anxiety, tension, depression, or despair. By increasing the metabolic rate, resistance to stress may be increased and the patient made more capable of facing daily tasks.

The syndrome of metabolic insufficiency (hypometabolic state) is perhaps one of the most common metabolic disorders seen in everyday practice. At the same time, it may go unrecognized or misdiagnosed for a number of reasons [1]: it has only recently received serious attention as a clinical entity; its symptoms are vague, nonspecific, and seldom totally disabling; it cannot be detected by thyroid function tests; and it is generally not relieved adequately by conventional medication. This syndrome is characterized by low normal or subnormal basal metabolic rate (usually −15 to −30%), by clinical signs and symptoms of deficient metabolism, and by normal thyroid gland function as indicated by normal values for serum protein-bound iodine, cholesterol, and radioactive iodine (I^{131})-uptake tests.[2]

Thus the syndrome of metabolic insufficiency differs from hypothyroidism in that it occurs in persons whose thyroid gland function appears to be normal. There is no reduced synthesis or output of thyroid products, as measured by I^{131}-uptake and protein-bound iodine tests. When it is established that the low basal metabolic rate is not caused by adrenal insufficiency, nephrosis, hypopituitarism, hypogonadism, anorexia nervosa, or malnutrition, the presence of metabolic insufficiency can be presumed.

An explanation for this condition has come various investigators since the discovery of sodiu thyronine (3,5,3′ L-triiodothyronine).[3] It has appe that L-thyroxine must be deiodinated to liothyr in the peripheral tissues before it becomes activ patients with metabolic insufficiency this conve ay be incomplete because of some defect: general ody tissue insensitivity to the thyroid hormone[4]; apid destroying, storing, or inactivation of thyroid ormone[5]; decreased permeability of the cells to hyroxin[1e]; or an intracellular defect.[6] Such a defect, vhatever its nature, leads to generalized or localized igns and symptoms. Chronic fatigue, somnolence, or ethargy are common. Also prominent are dry hair, lry skin, infertility, dysmenorrhea, menstrual irregularity, sensitivity to cold, joint and muscle aches and stiffness, obesity, irritability, emotional instability, and constipation. These are similar to the changes seen in hypothyroidism, but less severe. Each symptom or sign by itself may result from various disorders. However, several of these signs and symptoms, together with a low normal or subnormal basal metabolic rate, constitute the syndrome of metabolic insufficiency.

Patients with this disorder often do not respond to even large doses of desiccated thyroid.[7] An explanation for this has been based on the theory that in such patients even endogenous thyroid hormone is not utilized adequately. Sodium liothyronine, however, has been reported to produce both metabolic and clinical responses in a number of cases.[8] The present study was conducted, therefore, to evaluate the efficacy of sodium liothyronine in a large group of patients with metabolic insufficiency or specific metabolic disorders. The aims of this study were to survey the incidence of signs and symptoms in patients with metabolic insufficiency, and to define the syndrome more clearly; to evaluate the clinical efficacy of sodium liothyronine in patients with metabolic insufficiency or associated metabolic disorders; and to compare responses with those from desiccated thyroid, thyroglobulin, and thyroxine in previous treatments.

Materials and Methods

A total of 80 patients were studied. On the basis of clinical evidence, each patient was placed into one of two groups. In group 1, there were 51 patients who had been given a diagnosis of metabolic insufficiency. In group 2, there were 29 patients with specific (or localized) metabolic disorders such as obesity, infertility, salt and water imbalance, and gynecologic disturbances. The latter group included all patients with one dominant or severe disorder.

Group 1 consisted of 45 females and 6 males between the ages of 13½ and 53 years. The average age was 32.9 years. None of the group were myxedematous, nor could they be considered hypothyroid by usual standards. The predominant symptom was chronic fatigue, noted in 88% of the group. The predominant sign was obesity, seen in 75%. Also present in various combinations were menstrual disturbances, 67%; dry hair, dry skin, and/or brittle fingernails, 57%; nervousness, irritability, depression, and/or mental apathy, 51%; muscle or joint aching and stiffness, 47%; and sensitivity to cold, 43%. Puffiness of the face was also noted.

Protein-bound iodine levels were normal, ranging from 3.6 to 7.5 mcg. per 100 ml. of serum (table 1). Basal metabolic rates varied from normal (+2%) to subnormal (−40%). (Even though the basal metabolic rate was normal in some cases, if signs and symptoms of metabolic insufficiency were present, such cases were included.) Serum cholesterol levels, determined in 12 patients, were within normal limits. Other laboratory findings were negative.

Thirty-six of this group had been treated previously with desiccated thyroid, thyroglobulin, or thyroxine (table 1). The average tolerated dose was 2 to 3 grains (0.12 to 0.2 Gm.) of desiccated thyroid per day.

* Desiccated thyroid, thyroglobulin, or thyroxine
† No previous treatment or response unknown

Side-effects had developed in 18 of the group. Therapeutic responses had been excellent in none, good in 3, fair in 14, poor in 19, and undetermined in 15.

Group 2 consisted of 25 females and 4 males between the ages of 13 and 48. The average age was 29.8 years. Diagnoses were as follows: female sterility in nine patients, male infertility in three, gynecologic disorders in seven, primary obesity in five, and intractable salt and water imbalance in five (table 1).

Protein-bound iodine levels were found to range from slightly subnormal to normal, 3.2 to 7.6 mcg. per 100 ml. Basal metabolic rates varied from +1% to −19%. Other laboratory findings were negative, except results of sperm analyses in the infertile males and ovarian function tests in the infertile females.

Twenty-one of the group had been treated previously with desiccated thyroid, thyroglobulin, or thyroxine. Side-effects had been noted in 7 patients, and responses had been excellent in none, good in 4, fair in 3, poor in 16, and undetermined in 6.

* Excellent indicates successful pregnancy. Good indicates correction from anovulatory to ovulatory cycle or pregnancy that terminated by spontaneous abortion. Fair indicates relief of menstrual irregularities or improvement in type of cycle but not as consistent as in "good." Poor indicates no change.

Over a period of three to nine months, each patient was treated with sodium liothyronine. Starting doses varied from 5 to 25 mcg. daily. Maximum doses ranged from 10 to 100 mcg. daily. At no time were sodium liothyronine and thyroid preparations given simultaneously. A time interval of one to three weeks elapsed after previous drugs were withdrawn before the test drug was given. In this way, responses were not materially influenced by residual effects from previous medication.

Responses to treatment were rated according to relief of ectodermal, musculoskeletal, reproductive, and other objective signs; relief of fatigue, mental apathy, nervousness, and other subjective symptoms; and over-all clinical response as compared with previous therapies. The ratings were as follows: excellent, indicating complete remission of symptoms or a marked response in one to two weeks, especially when previous therapies had not evoked any response; good, indicating a marked though incomplete response, or remission of symptoms after more than two weeks; fair, indicating partial remission of symptoms, regardless of dosage; and poor, indicating no change in the patient's status. Controls or placebos were not considered necessary, since previous therapies could be used for comparative responses.

Results

Group 1.—Results of therapy with sodium liothyronine in group 1 were excellent in 23 patients, good in 23, fair in 4, and poor in 1 (table 2). In those patients showing good to excellent responses, the most common and beneficial response was loss of fatigue. With an increase in energy, many patients reported more alertness upon awakening, less need for midafternoon naps, and an ability to accomplish more work. Those patients who were nervous and restless, and those with emotional depression or anxiety, became calmer. This response generally paralleled an increase in a sense of well-being. Sensitivity to cold was relieved, as patients noted increased warmth during the winter months. Muscle and joint aching and stiffness subsided or completely disappeared.

Objective improvements, more reliable to the clinician but perhaps not as important to the patient, were also noted in those patients who showed excellent to good responses. Twenty-two of 38 obese patients lost weight; the average loss was 9.3 lb. (4 kg.). Dry hair and dry skin became oilier and smoother. Other disorders such as brittle fingernails, facial puffiness, and menstrual irregularity were relieved. To illustrate excellent responses, two typical case histories are presented below.

Report of Cases

CASE 1.—A 32-year-old female sought treatment because of chronic fatigue, vague muscle pains, obesity, and inability to conceive during the previous seven months. Her hair was thick and coarse, and her skin was smooth. She menstruated every 28 or 29 days, for 4 to 5 days. (Formerly, every 24 days for about 3.) The protein-bound iodine level was 3.6 mcg. per 100 ml. of serum, and the basal metabolic rate was −21% after many months of treatment with desiccated thyroid. Premenstrual smears showed a late secretory phase with increased estrogenic stimulation. Other laboratory and clinical findings were normal. The patient had been treated previously with 3 grains (0.2 Gm.) of desiccated thyroid daily for approximately six months. There was no change in symptoms during this treatment, and no toxic reactions were noted.

On Oct. 11, she was started on therapy with 5 mcg. of sodium liothyronine daily. At the end of one week, there was a marked improvement in her outlook and energy. The dosage was increased to 10 mcg. daily for the second week, after which time the patient was "feeling fine" and "sleeping better." Her hair was silkier, and muscular aching had subsided. The dosage of sodium liothyronine was gradually increased to 25 mcg. daily. On Nov. 25 (after six weeks), the patient reported she felt fine, had more energy, had no joint stiffness, and had "no complaints." At this time she had lost 9.5 lb (4.3 kg.) and her hair appeared to be soft and oily. Commenting on her loss of weight, she said, "Everybody notices the change in me." Rating: excellent response.

CASE 2.—A 32-year-old female presented chief complaints of chronic fatigue (especially in the afternoon) and tendency to gain weight. She had gained 30 lb. (13.6 kg.) during two years.

Other symptoms present were vague joint and muscle pain, mild sciatica, sensitivity to cold, and menorrhagia. The hair was slightly dry, the skin was rough, and the face was slightly puffy and pasty. There was no hirsutism. The palms were warm and moist. She menstruated every 28 days for about 6 days. She had had two miscarriages, as well as two completed pregnancies. The protein-bound iodine level was 5.1 mcg. per 100 ml. of serum, and the basal metabolic rate was —10% after prolonged treatment with desiccated thyroid.

This patient had been treated by several physicians for chronic fatigue and lethargy, without much success. In 1947, her basal metabolic rate was —17%. During treatment with 2 grains (0.12 Gm.) of desiccated thyroid daily, her basal metabolic rate had increased to —11%, but all symptoms had persisted to some degree. Medication was started with 12.5 mcg. of sodium liothyronine daily and increased to 25 mcg. during the second week. The patient reported that she began to feel better, had more vigor, and could "do more housework." Also, her skin was notably clearer. Treatment was continued at 25 mcg. daily. At the end of the fourth week, she had lost 12 lb. (5.4 kg.) and felt much improved. One month later she was completely free of symptoms. Muscle aching and pain had subsided, there was an increased feeling of warmth, and menstrual flow became shorter in duration. Rating: excellent response.

Maximum dosages given to patients in group 1 were 10 to 25 mcg. daily in 33 patients, 37.5 to 50 mcg. daily in 15, and 67.5 to 100 mcg. daily in 3. Side-effects of jitteriness, tachycardia, and nervousness were observed in two patients. These reactions disappeared completely within five days after medication was stopped. In the remaining patients, there were no side-effects, no significant changes in blood pressure or pulse during therapy, nor any signs of acquired refractoriness to sodium liothyronine.

Group 2.—Results of treatment with sodium liothyronine in group 2 were excellent in 13 patients, good in 12, fair in 2, and poor in 2 (table 2). The three patients with male infertility showed improvements in sperm count, in one case from 11 million cells per cubic centimeter to 45 million per cubic centimeter, with increased viability and survival of the sperm. Eight of the nine females with long-standing infertility showed normalization of ovulatory cycles. Four patients became pregnant. One of these aborted, so her response was labeled as good rather than excellent. Patients with gynecologic disorders generally showed a good response, except one patient with menopausal syndrome and one with oligomenorrhea. Both of the latter could not tolerate the drug.

The five patients with primary obesity showed weight losses ranging up to 54.5 lb. (24.7 kg.) during a nine-month period. In these cases, sodium liothyronine proved to be superior to desiccated thyroid. The five patients with intractable salt and water imbalance showed marked diuresis during treatment. Two patients in group 2 reported tachycardia, increased nervousness, and insomnia from sodium liothyronine. One was taking 12.5 mcg. daily; the other was taking 25 mcg. daily. The remaining 25 patients tolerated the drug satisfactorily. The over-all efficacy of sodium liothyronine in this group is illustrated by the case histories below.

Case 3.—A 31-year-old female had severe menorrhagia, in addition to several signs and symptoms of metabolic insufficiency. Presenting symptoms were chronic fatigue, insomnia, bitemporal headaches, groin pains, extreme sensitivity to cold, and stiffness of the joints. She stated that she worried excessively, was anxious, and had been given psychiatric treatment. Her hair was dry and sparse, and her skin was dry. Examination revealed no other abnormalities. Menstruation occurred every 30 to 35 days and lasted for about 7. Flow was heavy, and occasionally small clots were excreted. The protein-bound iodine level was 5.2 mcg. per 100 ml., and the basal metabolic rate ranged below —15%.

Sodium liothyronine was given in increasing doses up to 25 mcg. daily. At the end of two weeks, the patient showed a marked improvement and was more alert mentally. Her aches and pains had disappeared, and she reported a feeling of improved well-being. At the end of the second month, she had not been having headaches and signs of nervousness were gone. At the end of the third month, she felt much calmer ("Now I can take everything in my stride"). Menstrual periods had become more regular (25 to 30 days), less heavy, and excretion of clots had ceased. In addition, the patient had "more zest for living." Rating: excellent response.

Case 4.—A 31-year-old female presented chief complaints of obesity and oligomenorrhea. She had been overweight since adolescence and had "always felt lazy and sluggish." In recent years, she had had intermittent periods of amenorrhea, which lasted from 3 to 17 months. She had not responded adequately to 1 to 2 grains (0.06 to 0.12 Gm.) of desiccated thyroid daily and a 1,500-calorie diet. Treatment with 2 grains of thyroglobulin daily had resulted in only slight fluctuation in weight; mercurials had caused temporary diuresis but not reduction in weight.

The hair was slightly dry, the hands and palms were normal, and there was generalized obesity. Her height was 63.5 in. (160 cm.); weight 221.75 lb. (100.6 kg.); blood pressure, 138/84 mm. Hg; pulse rate, 84 beats. The basal metabolic rate was +6%, and routine laboratory tests showed no abnormalities.

Medication was started with 12.5 mcg. of sodium liothyronine daily, which was increased to 25 mcg. daily after two weeks. After three months, her periods had become more frequent (30 to 40 days apart), she felt much less depressed, had more energy, and her hair was smoother. Her weight at this time was 187.25 lb. (85 kg.), a loss of 34.5 lb. (15.6 kg.). As the dosage of sodium liothyronine was increased gradually to 50 mcg. daily during the next two months, her weight continued to drop at the rate of about 1 lb. (0.5 kg.) per week. At the end of nine months, her weight had dropped to 167.25 lb. (75.8 kg.), a loss of 54.5 lb. (24.7 kg.). Subjectively, the patient felt "much better" than she had in years and had no complaints. Rating: excellent response.

Case 5.—A 32-year-old female was given a diagnosis of intractable idiopathic edema. She reported that she had always had some premenstrual edema and tension, but recently edema had persisted throughout the menstrual cycle. The edema was intensified for two to three days at midcycle and four to five days premenstrually, and occasionally she gained as much as 10 lb. (4.5 kg.) in 24 hours.

Her history showed that she had had a cystic left ovary removed six years previously. A year afterwards, she had noted swelling of the entire body premenstrually. Treatment with mercurials had afforded only temporary relief, whereas an oral medication [9] prevented or relieved the premenstrual symptoms. She had been married two years, but had never been pregnant. The menses occurred every 28 days and lasted 3 to 5 days and varied in amount of flow. Physical examination revealed a well-developed female, 65.5 in. (165.10 cm.) tall, weighing 152.5 lb. (69.1 kg.). No abnormalities were seen, other than moderate obesity and edema of the ankles. The protein-bound iodine value was 6.5 mcg. per 100 ml. of serum, and other test values were normal.

On Sept. 8, the patient was started on therapy with 12.5 mcg. of sodium liothyronine daily, and her condition was maintained with a *high-protein, low-sodium diet.* The dosage was increased to 50 mcg. daily during the next month. On Oct. 28, she reported slight bloating and edema, although her weight was essentially unchanged (152.75 lb. [69.2 kg.]). On Nov. 11, on the 27th day of her 28-day cycle, the patient was feeling fine "for the first time in years." No swelling was noted, and there was no premenstrual tension. Previously, she had gained at least 3 or 4 lb. (1.3 or 1.8 kg.) at such times. On Nov. 18, the patient was still improved, although she had ingested a large volume of fluids. No postmenstrual edema was present, and her weight was 148.75 lb. (67.5 kg.). She had experienced normal flow. On Dec. 2, the patient had no swelling or edema, and roundness of the face had disappeared. She reported that she was wider awake during the day, and slept better at night. The dose of sodium liothyronine was reduced to 25 mcg. daily. On Dec. 9, there was slight premenstrual swelling, but less than previously. She had been eating as she wished, except for a minimum of salt.

The reduced dosage of sodium liothyronine seemed to cause some exacerbation of symptoms, so it was increased again to 50 mcg. daily during the next month. The patient was seen each month until May 10, and she had remained improved. There was no edema either before or after menstruation, and the patient was free of all symptoms. Rating: excellent response.

Comment

The results of this study have shown a relationship between metabolic insufficiency and many common disorders. Most common was fatigue, a complaint of 88% of group 1. Obesity, menstrual irregularities, dry hair and skin, and nervous or emotional disorders were seen in more than 50%. Relief of these and other symptoms with sodium liothyronine, compared to the relatively slight response with desiccated thyroid, thyroglobulin, or thyroxine, supports the theory that these symptoms were caused by insufficient metabolism at the cellular level. In the patients with specific metabolic disorders (group 2), it appears that the basic defect causing metabolic insufficiency was severe in certain organ systems. Infertility, obesity, and various gynecologic disorders were shown to be relieved by metabolic stimulation.

Approximately 15% of the patients in this study had been referred by psychiatrists. Another 5% had undergone psychotherapy or analysis, and one had been given electroshock therapy. It is important to note that most of these patients reported considerable relief of the mental and emotional symptoms from sodium liothyronine. Such responses suggest that daily stress created by demands on a fatigued and metabolically insufficient patient can cause nervousness, anxiety, depression, or despair. By increasing the metabolic rate, resistance to stress may be increased, and the patient is more capable of facing daily tasks. This theory has, in fact, been supported by Timaras and Woodbury,[10] who have recently shown that in rats sodium liothyronine increases brain excitability, enhances the capacity of the brain to support maximal electroshock seizures, and shortens postictal depression. Further studies of the role of metabolic insufficiency in mental and emotional disturbances are, therefore, recommended.

Summary and Conclusions

The clinical effects of sodium liothyronine have b determined in 51 patients with metabolic insufficie and in 29 patients with specific metabolic disorde The criteria for diagnosing the syndrome of metab insufficiency are outlined as (1) low normal or su normal basal metabolic rate, (2) multiple coexiste signs and symptoms of deficient metabolism, a (3) normal thyroid gland function, as indicated b protein-bound iodine or radioactive iodine (I^{131}) uptake tests.

Responses to sodium liothyronine generally we superior to responses to desiccated thyroid, thy globulin, or thyroxine. Good to excellent [illegible] with sodium liothyronine were elicited in 46 of 5 (or 90%) of the patients with metabolic insufficienc Of this same group, 36 patients had previously be treated with desiccated thyroid, thyroglobulin, thyroxine. Only three, or 6%, had shown good excellent responses.

Included in the study also were 29 patients with t following diagnoses: female sterility, male infertili gynecologic disorders, obesity, and intractable s and water imbalance. Responses were good to exc lent in 25 of these 29 patients. Thus, the rela ion of such disorders to insufficient metabolism is gested. Side-reactions of nervousness, insomnia, tachycardia were noted in 4 of the total of 80 patie No signs of acquired intolerance were observ *From the results of this study, it is concluded t sodium liothyronine is a highly effective and safe the peutic agent for treating patients with metaboli insufficiency and other nonmyxedematous metaboli disorders.*

NEUROLOGICAL CASE HISTORIES OF TWO OLYMPIC CHAMPIONS

Ernst Jokl, M.D., Lexington, Ky.

Disease and physical disability may serve as strong incentives for the attainment of motor performances, some of them of a high order of complexity, and of athletic excellence. In one case motivation, possibly from conflict, produced achievements revealing a new insight into the scope of compensatory adjustment of the nervous system. The second case indicates the extent to which an established neuromotor pattern can be projected into previously untrained skeletomuscular regions. Both cases illustrate the possibility of complete functional rehabilitation after major disablement.

While accompanying the United States Olympic athletes to Melbourne, Australia, in November, 1956, I noted that one of the most distinguished members of the track and field team, Harold V. Connolly, U. S. champion and world record holder in hammer throwing, was afflicted with a combined upper and lower left brachial plexus paralysis (Erb-Duchenne-Klumpke-Déjerine type).

Hammer Throwing Champion with Combined Upper and Lower Left Brachial Plexus Paralysis

Connolly, aged 25, a young man of intelligence and modesty and of strong moral principles, was able to give a precise history of his affliction. It appears that he suffered an injury at birth. As far back as he could remember, the left arm had hung at the side as it does at present: internally rotated at the shoulder with the elbow extended and the hand pronated. The whole left upper extremity is underdeveloped, a fact which is all the more evident as the right arm is unusually powerful and extremely well trained. The difference in length between the two arms is 4.5 in. The size of the left hand is less than two-thirds that of the right. Circumferential measurements of the extremities differ by 3.5 in. (17.5 versus 14) for the upper; by 2.5 in. (13.5 versus 11) for the lower arm, and by 1 in. (8.25 versus 7.25) for the wrist.

Paralysis of the left deltoid renders abduction at the shoulder virtually impossible. Flexion at the left elbow is performed with feeble power on account of paresis of the flexors, extension can be effected, as the triceps functions well, outward rotation at the shoulder is almost completely lost owing to paralysis of the spinati; biceps and supinator jerks cannot be elicited. There is wasting and weakness of the ulnar flexors of wrist and fingers and paralysis and wasting of the small muscles of the hand, which at rest assumes a semi-closed position resulting from the unopposed action of the long flexors of the fingers.

Sensory symptoms are in evidence, e. g., neuritic pains in the upper part of the arm. The whole left upper extremity is colder and more sensitive to touch along the radial margin and less sensitive along the ulnar. Involvement of the cervical sympathetic nerves is indicated by hyperhidrosis; the skin of the arm feels waxy, the veins of the forearm are soft, in contrast to those of the right side, which are strong-walled and of good tone and tension; the growth pattern of the fingernails of the left hand is abnormal. The patient reports of involuntary twitching of the musculature of the afflicted arm.

Connolly displays a remarkably clear insight into the nature of the psychological and social conflict with which his disability has confronted him from earliest childhood. The conflict was resolved by this mature and courageous man in a manner which eventually enabled him to become the greatest hammer

thrower in the history of athletics. At the same time he completed his academic studies with distinction. For several years Connolly made a scientific study of different methods of athletic training as practiced in various countries. Two years prior to the 1956 Games, he traveled to Europe to consult with a number of famous coaches and former Olympic champions in hammer throwing. He took up weight lifting in order to bring about the greatest possible degree of muscular hypertrophy. In the process he not only developed a powerful right but also, though of course to a much lesser degree, attained a good deal of improvement of the paretic left arm.

On two occasions he suffered fractures. Lying on his back he gripped a bar weighing 125 lb. in his powerful right and the weak and paretic left hand. In trying to lift the weight the atrophic humerus of the left arm broke.

It is a measure of Connolly's solidity of purpose that such major setbacks failed to deflect him from his objective. In both instances he resumed his training as soon as union of the fractured bone had taken place. In October, 1956, he established a new world record in throwing the 16-lb. weight 224.10½ ft. At Melbourne, in the tensest hammer throwing competition ever staged, he won the gold medal—the first American to do so in this event since 1924—defeating among others the champions of Russia, Hungary, Germany, Poland, and England and establishing a new Olympic record. A few days after his return to the United States late in December, he bettered the world record for throwing the 35-lb. weight with a toss of 66 ft. 8.5 in., whereafter the State Department sent him on a goodwill trip to Europe.

Diagnostic Features.—This case calls for comment from several angles. First, the diagnostic aspect. The paralysis of the left arm is of such a kind as to leave no doubt that this is a combined upper as well as lower plexus paralysis, the branches to the branchial plexus from the fifth, sixth, and eighth cervical as well as from the first dorsal nerves being involved.

In the typical Erb-Duchenne upper plexus type of paralysis, movements of wrists and fingers remain unaffected and sensory symptoms are usually absent. In the typical Klumpke-Déjerine lower plexus type of paralysis the fifth and sixth cervical contributions are spared while the first dorsal nerve and at times also the eighth cervical branches are commonly damaged.

In this case upper and lower brachial plexus paralyses are in evidence. Both anesthetic and analgesic, as well as hyperesthetic and hyperalgesic, symptoms are demonstrable. The presence of autonomic and trophic symptoms points to participation of the cervical sympathetic nerves, though pupillary abnormalities are not present.

Analysis of Athletic Performance.—Careful attention was paid to Connolly's technique of throwing the hammer. Wearing a thick glove over the paretic left hand he exerts with it a steering influence upon the steel grip of the hammer, maintaining it fully during the first two turns in the ring. During the third turn, in which he reaches a maximal rotatory velocity, the left hand slips far down so that eventually it holds the steel grip of the hammer with the tips of the fingers only, the full weight being carried by the right hand. "After my best throws the ends of my left fingers are black with blood blisters," Mr. Connolly reports.

Motivation and Quality of Performance.—Disease and physical disability may serve as strong incentives for the attainment of motor performances, some of them of a high order of complexity, and of athletic excellence. A case of a swimming champion with dementia paralytica and of an artist afflicted with advanced multiple sclerosis with advanced paresis and tremor of the right arm which she used in her work have been described elsewhere.[1]

Motivation as well as performances of the category under discussion do at times reflect rather unusual patterns. There is the story, reported some years ago of a frankly psychopathic man, 43 years old, who prior to the war was involved in criminal procedures; who during the war won numerous decorations for conspicuous bravery in combat; and who after the war without demonstrable reason, was unable to find place in society and became an insolvable problem to the welfare authorities.

Lord Byron's life and literary achievements would be inexplicable without appreciation of the fact that this gifted man was deeply disturbed and constantly agitated by the knowledge of being afflicted with a irremediable and severe physical disability. But Diem has also detailed a revealing scene, with all its psychopathic connotations, in which Byron, refusing to accompany the funeral procession at his mother's death, gave expression to his grief by staging in the large hall of his ancestral castle in Newstead Abbey a long and violent boxing fight, gloves and all, against *his friend Rushton.*

Arthur Newton, former world record holder in running distances of up to 100 miles, describes how he decided at the age of 40 to take up competitive athletics in order to demonstrate to the world that in his opinion an injustice was done to him in a protracted litigation with a government department in Natal though it was found he had in fact not even a semblance of a case to argue. For many years, the logic of his decision sufficed to induce him to undergo the most strenuous training and to take part in such races as one from New York to Los Angeles.[4]

By contrast, Connolly's story is distinguished by the fact that the motivation underlying *his prolonged* training is rational in terms of his personal objective, dignified in execution, and, from the point of view of its social evaluation, of a high order of maturity. This young man's motor achievements reveal a new insight into the scope of compensatory adjustment of the nervous system.

Reestablishment of Performance Capacity in Contralateral Extremity After Amputation of Right Hand

"The nervous system" Hughlings Jackson [5] wrote in 1874, "is physically double. I wish to show that it is double in function also, and further, in what way it is double in function." The following observation throws light on the significance of Jackson's classic statement.

At the Olympic Village in Melbourne in 1956, I examined Karoly Takacs, 46 years of age, member of the Hungarian team. Takacs had represented Hungary in the pistol shooting competition at the Berlin Games in 1936, holding at that time ral national and international championships in this sport. 1938 Takacs was involved in an accident which necessitated utation of the right arm midway between elbow and wrist. his discharge from the hospital Takacs decided to continue peting by shooting with the left hand, which he had never s used prior to the amputation. In 1939 he won the world mpionship in pistol shooting at Lucerne, Switzerland. At Olympic Games in London in 1948 and in Helsinki in 1952 was awarded gold medals for the same event. The 1956 npetition in Australia was his fourth Olympic contest.

Comment.—Several features of this case call for mment. First, that the excellence of Takacs' athletic rformances is so great as to place his preamputation well as postamputation attainments into a class of eir own. Secondly, that initially the training which tablished his world fame as a pistol shot was con- ned to the right arm. Thirdly, that the switch-over to e left arm was achieved within the comparatively ort time of eight months. And fourthly, that from en on Takacs continued to improve his athletic mpetence.

Hemispheric Dominance.—This report indicates the tent to which an established neuromotor pattern can e projected into previously untrained skeletomuscular gions. It also raises the question of the dominance one cerebral hemisphere over the other. Prior to e amputation, Takacs was right-handed. It would, he pointed out, not have occurred to him to shoot ith his left hand. The postoperative switch involved ot only the motor aspect of the skilled performance ut also its sensory counterpart, especially in respect the functional integration of the tactile, propriocep- ve, and visual components, of which Adrian has iven a masterly account.[6]

> The visual messages are the most complex and the most portant of all those reaching the human brain. In other imals hearing and smell may be the dominant senses, but in r brains the olfactory pathways have shrunk and smells play very small part in our thoughts and decisions. In all the rtebrates, however, the eyes seem to have dictated the eneral arrangement of the cerebral hemispheres. Owing to the amera structure of the eye an object on the left is focused on e right half of the retina and vice versa. Now the natural rrangement would seem to be that the right half of the retina either eye should be connected with the right cerebral emisphere and the left half of the retina with the left hemi- here, and this is in fact accomplished by a sorting out of the erve-fibres at the optic chiasma before they enter the brain. he result is that an object on the left is signalled by a visual essage which is sent to the right cerebral hemisphere. Now if e object came into contact with the left side of the body or the left hand were put out to touch it, it would be confusing the tactile messages were sent to one side of the brain and the visual to the other. What seems to have happened, therefore, is that the crossing-over of the visual message has made it necessary for all the sensory pathways to cross over, so that all the information reaching one side of the brain comes from the opposite side of the body and its surroundings; and as all the information goes across to the opposite hemisphere, the orders for the muscles must also be elaborated in that hemisphere and the messages for them must come back across the midline on their way down to the spinal cord.

Summary.—This case report then is concerned with the reestablishment of the performance capacity in an Olympic champion in pistol shooting who had attained fame while competing with the right arm and who, after amputation of the dominant extremity, once more became world champion, using the left arm. It emphasizes (1) the part played by the central pattern in the attainment of highly skilled neuromotor performances, (2) the significance of Hughlings Jackson's statement regarding the functional bilaterality of the nervous system, (3) the integrated nature of the performance adjustment after amputation, and (4) the possibility of complete functional rehabilitation after major disablement.

It also raises the question whether the cerebral component underlying the extraordinary neuromuscular efficiency of this patient prior to the amputation explains the transfer to the contralateral extremity.

The German poet, Gotthold Ephraim Lessing in his drama, "Emilia Galotti" wrote that Raphael would have become an immortal painter even if he had been born without arms. Takacs' story corroborates the validity of Lessing's literary imagery.

I am indebted to Lord Adrian (University of Cambridge, England) for permission to quote from his book.

Fatal Machine Accidents on Farms.—Each year more than 2,000 people in the United States, or 1.3 per 100,000 population, are fatally injured in accidents involving machinery. . . . Over two fifths of all the fatal injuries in machine accidents occur on farms. . . . Tractors account for a considerable loss of life on the farm; overturning is the most common hazard, and frequently results from running the tractor too fast, carrying excessively heavy loads, and from operating it along steep slopes or too near deep ditches. Self-propelled combines, corn pickers, hay balers, hoists, and feed grinders are among the other types of machines usually involved in fatal farm accidents. Although a majority of the deaths from farm equipment are among adults, an appreciable number are among children, some of them quite young.—Fatal Machine Accidents, *Statistical Bulletin of the Metropolitan Life Insurance Company,* October, 1956.

FETOPELVIC GRADING OF BREECH PRESENTATIONS

D. Frank Kaltreider, M.D., Baltimore

In the management of a breech presentation, three factors must be considered in order to decide between vaginal delivery and cesarean section. These are (1) pelvic size, (2) pelvic shape, and (3) estimated fetal weight. Pelvic size can be accurately measured by x-ray pelvimetry. Unless the infant is premature, vaginal delivery is contraindicated in flat pelves with an obstetric conjugate of less than 10 cm. Fetal weight is best estimated by having four or more examiners give an estimate without the knowledge of others and averaging the estimates. In addition to the above three factors, the behavior of the sacrum and consideration of uterine inertia must also be taken into account.

The breech presentation has been a fascinating and depressing problem to obstetricians for many years. It has been fascinating in that, if one is able to extract the breech satisfactorily without injury, one has the sense of accomplishment. In addition, the breech is frequently associated with such problems as congenital anomalies of the uterus, placenta previa, and contracted pelves. It is depressing because so many breech infants die because of prematurity, prolapse of the cord, intracranial hemorrhage, and anoxia.

During the past years, there have been many excellent papers on the general management of the breech, with particular reference to vaginal delivery. The emphasis on cesarean section has been lacking. There has been a hesitation to analyze the pelvic structure, pelvic size, and weight of the infant in order to determine whether any particular breech should be delivered vaginally. Much of this has been done by guesswork, and, when there has been indecision, the ultimate decision has usually been cesarean section rather than vaginal delivery. I will attempt to lay down some criteria for cesarean section in those pelves which are contracted.

Material

At the University of Maryland Hospital from Jan. 1, 1950, to June 30, 1956, there have been delivered 19,414 infants weighing over 400 Gm. Of these, 781 were of the breech presentation, or an incidence of 4.02%. When twins were eliminated, there were 634 breeches occurring in 18,954 single pregnancies, or an incidence of 3.34%. The disturbing factor is the perinatal loss. Table 1 demonstrates the number of single breech deliveries according to weight and the perinatal outcome. It will be noted that even in term births the perinatal loss was high (7.5%). The over-all loss was 23.3%. These figures are usually corrected by eliminating fetal death in utero, patients with hemorrhage and toxemia, and those infants in which there have been prematurity, congenital anomalies, and erythroblastosis. The corrected loss drops in service patients to 2.3% and in private patients to 0%.

I do not feel that this is a proper approach to the problem. I should rather look at the situation as a 23.3% loss and attempt in some fashion to correct this by better obstetric practice to a lower loss rather than by statistical correction.

There were 774 cesarean sections during this pe
of time among the 18,954 single pregnancies, or 4
However, among the breeches this incidence was
It is not necessary to go far into statistical analys
find why the incidence of cesarean section a
breeches is so much higher than it is among the
presentations combined. For example, among the
breech presentations, there were 13 placenta pre
a ratio of 1 in 49, while in the other presentations
ratio was 1 in 346. In patients who had previously
a cesarean section, breech was frequently the deci
factor as to abdominal or vaginal delivery. In t
patients the ratio was 1 in 35, while in the other
entations it was 1 in 103.

In those patients in whom there was either a l
infant or a borderline or actual contraction of
pelvis, cesarean section was done once in ever
breeches; in the remainder of the patients, once i
cases. This is sufficient to raise the cesarean sec
rate from 4% among all presentations to 11% am
the breech presentations.

The combination of breech and contracted pelv
a comparatively small factor among any group of
tients. When an obstetrician is faced with the prob
of a contracted pelvis and a breech presentation,
decision as to the type of delivery is an arbitrary
Guesswork has played the major role in the decisi
for abdominal delivery. We have had this combinati
53 times, 36 times in primigravidas and 17 times i
multigravidas. The primigravidas were delivered v
ginally 17 times, with one fetal loss; cesarean sectio
was used 19 times, with one fetal loss. The vagin
fetal loss is inexcusable, in that this patient's labor wa
over 36 hours in length with aberration of the fet

From the Department of Obstetrics and Gynecology, University of Maryland School of Medicine.

Chairman's address, read before the Section on Obstetrics and Gynecology at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

rt rate just prior to delivery. The cesarean section l loss is unfortunate. This section was done early abor; the infant was born in good condition but d in the early neonatal period. Autopsy showed rked subarachnoid hemorrhage. Among the multi- vidas, 11 were delivered vaginally, with one fetal s, and 6 were delivered by cesarean section. All of multigravidas delivered by section had had a vious cesarean section. The reason for the one fetal s in the vaginal group could not be determined.

Table 1.–*Perinatal Loss in 634 Breech Presentations*

Weight, Gm	Total No	No Living	Died No	Died %
400-1,000	73	2	71	97.2
1,001 1,500	42	13	29	69.0
1,501 2,000	46	24	22	47.8
2,001 2,500	62	47	15	24.2
2,501 and over	411	380	31	7.5
otal	634	466	168	23.3*

When corrected for prematurity, twins, fetal death in utero, anomalies, orrhage, and erythroblastosis, the mortality for service patients is % and for private patients 0%

There were 25 women with pelves contracted at the let alone; 13 of these were delivered vaginally, with fetal losses, and 12 by cesarean section with one fetal ss. Twenty women had midplane contractions, of hom 12 were delivered vaginally; and 8 had a con- acted inlet and midplane, of whom 3 were delivered aginally. Since I do not recognize outlet contraction s a pure entity and feel that the outlet and midplane hould be considered as one, outlet contractions are rouped with midplane contractions.

Selection of Type of Delivery

In an attempt to put into concrete form criteria by which one may be guided in the selection of delivery f the breech presentation, three factors must be considered. They are pelvic size, pelvic shape, and estimated fetal weight.

Pelvic Size.–The pelvic size can be accurately measured with only a 1 or 2% error by many of the fine methods of x-ray pelvimetry such as the Thoms, the avert-Steele, or the Caldwell-Moloy methods. These are excellent for determining pelvic shape as well as pelvic size. The most important of the measurements are the obstetric conjugate and the transverse diameter of the inlet at the superior strait and the interspinous and anteroposterior diameter of the outlet at the lower pelvis. Mengert has described areas at these two levels. The inlet area is obtained by multiplying the obstetric conjugate and the transverse diameter: 100%, or normal, is 145 sq. cm.. and 85% of normal, or 123.25 sq. cm., he has designated as borderline. The midplane area is obtained by multiplying the interspinous diameter and the anteroposterior diameter of the midplane. One hundred per cent, or normal, is 125 sq. cm.; 85%, or 106.25 sq. cm., is borderline. As the areas at either plane diminish, so does the incidence of successful vaginal delivery in normal-sized infants. Mengert has ably demonstrated this, and it has been corroborated. This fact will be used later in developing the criteria.

Pelvic Shape.–The after-coming head is accepted well by the normal-sized or even slightly contracted gynecoid and anthropoid pelvis. The head willingly enters the pelvic cavity with the occiput anterior. These two shapes may be considered good ones for the after-coming head. The fact that an after-coming head does not fit well into the flat pelvis has been recognized for many years. The head must enter the pelvis as an occiput transverse and sometimes has to be "rocked" from side to side in order to traverse the pelvic inlet. This may well cause dystocia. If the obstetric conjugate is less than 10 cm., the problem becomes acute. Unless the infant is premature, vaginal delivery is contraindicated in flat pelves with an obstetric conjugate of less than 10 cm. In the android pelvis, particularly when it is smaller than normal, the head has a tendency to enter as an occiput transverse and may well rotate to an occiput posterior as the lower pelvis is reached. When in addition there is funnelling of the pelvis, a major pelvic obstruction is met. Unless the android pelvis is large, it is a poor shape for the after-coming head.

Estimation of Fetal Weight.–All of us are aware that estimating fetal weight prior to delivery is difficult. In this group of patients there was a range from −934 Gm. to +912 Gm. of error when single estimations were used. The average error was an underestimation of 113 Gm. We have attempted to solve the fetal weight problem in the following manner: in any patient, four or more examiners estimate the fetal weight; this is done independently and without the knowledge of the others; these weights are then averaged. There is a tendency in breech presentations, as in all presentations, to overestimate small babies and underestimate large babies.

Table 2.–*Fetopelvic Grading in Breech Presentations**

Pelvic Size (Mengert's Area)	Pelvic Shape	Estimated Fetal Weight, Gm (Lb)
0 Over 90%	0 — gynecoid	0 Premature under 2,500 (5.5)
1 90% to 85%	0 — anthropoid	1 Small 2,500-3,100 (5.5-7)
2 85% to 80%	2 — platypelloid	2 Average 3,100-3,600 (7-8)
3 79% and under	2 — android	3 Large over 3,600 (over 8)

* Grading of 0 to 4 indicates vaginal delivery and 5 and over indicates cesarean section, with following exceptions: (1) platypelloid pelvis with obstetric conjugate greater than 10 cm. is graded 0; (2) transverse diameter less than 10.5 cm. in anthropoid pelvis is graded 2; and (3) any infant weighing over 4,000 Gm. should probably be delivered abdominally

Criteria.–In order to arrive at a graphic representation of criteria for vaginal delivery of breeches, each of the major factors discussed above has been weighted (table 2).

Pelvic Size: At either the inlet or the midplane or both, a Mengert's area of above 90% is graded 0; areas of 85 to 90% are graded 1; those of 80 to 85% are graded 2; and 79% and below are graded 3.

Pelvic Shape: The gynecoid and anthropoid pelves cause very little difficulty as to shape and are graded 0; the platypelloid and android pelves may cause major trouble and are graded 2. However, there are two exceptions. If in the anthropoid pelvis the transverse diameter is less than 10.5 cm., a grade of 2 should be made. If in a platypelloid pelvis the obstetric conjugate is greater than 10 cm., the platypelloid shape should be graded 0.

TABLE 3.—*Grading of Breeches in Contracted Pelves*

	No. of Women in Grade					
	2	3	4	5	6	7
Vaginal delivery	1	13	9	3	2	0
Primary section	0	2	5	9	2	1
Repeat section	0	1	2	2	1	0

Estimated Fetal Weight: Infants below 2,500 Gm. (5.5 lb.) (prematures) are graded 0; those weighing between 2,500 and 3,100 Gm. (5.5 and 7 lb.) are graded 1; between 3,100 and 3,600 Gm. (7 and 8 lb.), 2; and over 3,600 Gm. (8 lb.), 3.

Each patient is then graded from 0 up to a possible 8. The 53 patients with contracted pelves described above were graded, and the results can be seen in table 3. In the vaginal group, five patients were graded 5 and 6. One baby died, and the mothers of three of the remainder were multigravidas. They probably should have been delivered abdominally. In the primary cesarean section group, seven patients were graded 3 and 4. They had the following complications: one had a previous myomectomy, one had a tuberculous hip, and four had acute toxemia. These added problems entered into the decision for abdominal delivery.

Two hundred forty-seven patients with breech presentations had x-ray pelvimetry. Table 4 shows how these were graded. The indications for the primary sections were as follows: grade 0, hemorrhage in one patient; grade 1, erythroblastosis and diabetes in one patient each; grade 2, toxemia in one patient; grade 3, uterine inertia in one patient and nonpelvic indications in four; grade 4, uterine inertia in one patient, toxemia in three, and nonpelvic indications in one; grade 5, nonpelvic indications in three patients, elective section in four, and obstructive l in two; grade 6, nonpelvic indications and elective tion in one patient each; and grade 7, elective sec in one patient.

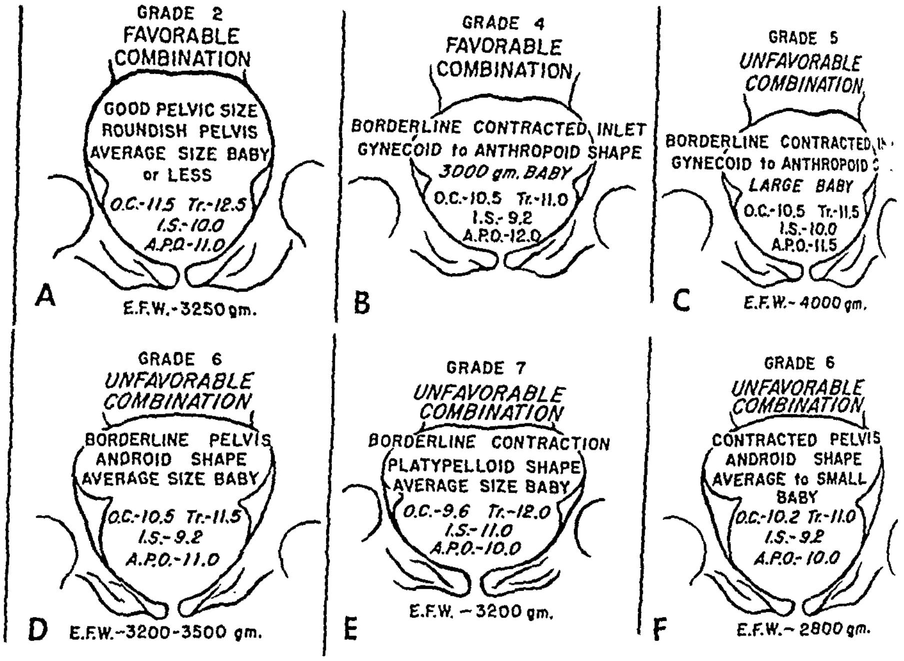
TABLE 4.—*Grading of Breeches in 247 Women Undergoing X-ray Pelvimetry*

	No. of Women in Grade								
	0	1	2	3	4	5	6	7	Total
Vaginal delivery	8	48	63	57	21	9	3	0	209
Primary section	1	2	1	5	5	9	2	1	26
Previous section	1	0	1	4	2	2	2	0	12
Total	10	50	65	66	28	20	7	1	247

The causes of the perinatal deaths were as foll nonpertinent anoxemia in 10 babies, congenital a alies in 3, trauma in 1 (grade 6), and intracr hemorrhage in one (grade 1). It appears reason with the fetal loss in grade 6 and the proved c of obstructive labor in grade 5 that levels higher t 4 could be dangerous to the infant if it is delive vaginally.

On this basis it is felt that patients graded 0 4 may be delivered vaginally; those graded 5 t should be delivered abdominally. There are two ceptions in the patients graded 4: (1) if the o ric conjugate is less than 10 cm. and (2) if the mated fetal weight is over 4,000 Gm. (9 lb.). T statistical data above do not prove that this sy of grading is valid. However, they may be suitab for practical use.

There are two other major considerations that not be weighted satisfactorally. One is the behav of the sacrum. If the sacrum has a good hollow a inclines posteriorly, one can expect little difficulty w the head. If the sacrum is straight and inclines fo ward, shortening the anteroposterior diameter of t outlet, then one can expect difficulty with extracti The second consideration is uterine inertia. Wh there is a combination of a suspect pelvis and inert regardless of the presentation, cesarean section is t better part of valor.



Examples of favorable and unfavorable combinations in breech presentat OC=obstetric conjugate, Tr.=transverse diameter of inlet, IS=interspinous diame and *APO=anterposterior diameter. A, pelvic size and shape grade 0 and estima* fetal weight (EFW) 1 to 3, depending on weight; total 1-3. *B*, pelvic size 3, pel shape 0, and *EFW 1; total 4. C, pelvic size 2, pelvic shape 0, EFW 3; total* 5. pelvic size 2, pelvic shape 2, EFW 2; total 6. *E*, pelvic size 3, pelvic shape 2, EF 2; total 7. *F*, pelvic size 3, pelvic shape 2, EFW 1; total 6.

mples of *Grading.*—The following examples may
ısidered to show some of the favorable combina-
(see figure).
\ pelvis of good size, with a roundish shape of
a gynecoid or slightly anthropoid type, and an
ge-size baby. One may not expect difficulty when
three factors are present in this form. This pa-
would have a grading of 1 to 3 depending on the
t's size (see figure, *A*).
A pelvis with a contracted inlet (Mengert's area
85%) with a gynecoid or anthropoid shape and
timated fetal weight of 3,000 Gm. Such a pelvis
have an obstetric conjugate of 10.5 cm., a trans-
diameter of the inlet of 11 cm., an interspinous
eter of 9.2 cm., and an anteroposterior diameter
e outlet of 12 cm. This patient would be graded
e figure, *B*).
e following combinations may be considered un-
able:
A borderline pelvis of any shape and a large
t. For example, an estimated fetal weight of 4,000
and a pelvis in which the inlet has an obstetric
ıgate of 10.5 cm., a transverse diameter of the
of 11.5 cm., an interspinous diameter of 10 cm.,
an anteroposterior diameter of the outlet of 11.5
would be graded 5 (see figure, *C*). Certainly a
)-Gm. infant would run the risk of major trauma
vaginal delivery.

2. A borderline pelvis of android shape, with an average-sized infant. For example, an obstetric conjugate of 10.5 cm., a transverse of the inlet of 11.5 cm. with a typical wedge-shaped pelvis with sharp spines in which the interspinous diameter is 9.2 cm., an anteroposterior diameter of 11 cm., and an estimated fetal weight of 3,200 to 3,500 Gm. would be graded 6 (see figure, *D*).
3. A bordeline contraction with a platypelloid shape of the pelvic inlet and an average-sized infant. For example, an obstetric conjugate of 9.6 cm., transverse diameter of the inlet of 12 cm., interspinous diameter of 11 cm., and an anteroposterior diameter of the outlet of 10 cm. with an estimated fetal weight of 3,200 Gm. would be graded 7 (see figure, *E*).
4. A contracted pelvis with an android shape and an average to small infant. For example, an obstetric conjugate of 10.2 cm., transverse diameter of the inlet of 11 cm., an interspinous diameter of 9.2 cm., and an anteroposterior diameter of the outlet of 10 cm. with an estimated fetal weight of 2,800 Gm. would be graded 6 (see figure, *F*).

Summary

Three variables affect the decision for the method of delivery when the presentation is a breech. They are pelvic size, pelvic shape, and estimated fetal weight. These variables have been weighted, allowing each patient to be graded for decision for vaginal or abdominal delivery.

TREATMENT OF OBESITY WITH PHENMETRAZINE HYDROCHLORIDE, A NEW ANOREXIANT

Charles Ressler, M.D., New York

By means of a double-blind procedure, 30 obese patients were tested to measure the effectiveness of a new anorexiant. The total weight lost and the average weight lost weekly by each patient were five times as great for those on therapy with the active drug as compared to those on therapy with a placebo. No special stress was placed on diet, although the elements of a well-balanced, 1,100-calorie regimen were explained. There were no unusual side-reactions, subjective complaints, or changes in physical findings to indicate toxicity of the drug.

henmetrazine hydrochloride is a new anorexiant.
s an oxazine derivative with sympathomimetic
)erties, and its reported action is suppression of
etite, with minimal cardiovascular and central
'ous system stimulation. In animal experiments[1]
lethal dose was about five times that of ampheta-
e, while the stimulative effect was about one-
ı. Clinical use was originated in Germany, where
ıeike[2] gave 50 patients a 25-mg. tablet twice daily
10 weeks and found that all patients lost weight
n average rate of 1.9 lb. (0.9 kg.) per week. In the
ted States, Gelvin, McGavack, and Kenigsberg[3]
orted on a study with a double-blind placebo con-

---

om the Second (Cornell) Medical Division, Endocrine
c of Bellevue Hospital.

trol in which phenmetrazine produced an average weekly loss of 0.9 lb. (0.4 kg.) in the 45 patients. No significant toxic results were encountered.

Method

We were supplied with two identical tablets labeled tablet A and tablet B. One was phenmetrazine, 25 mg., and the other a placebo, but the governing code was known only to the manufacturer. As obese patients were referred to the endocrine clinic for weight reduction, we alternately placed one on a regimen of tablet A three times a day one-half hour before meals and the next on a regimen of tablet B three times a day one-half hour before meals, until 36 patients were included. This was done in routine manner, with no attempt at selection of cases. Regular histories were taken and physical examinations performed on each patient, with laboratory studies including urinalysis, complete blood cell count, serology, and in most cases determinations of blood cholesterol level and basal metabolic rate.

During the first interview the elements of a balanced 1,100-calorie regimen were explained orally, and from then on no special stress was placed on diet. Patients were seen at two-week intervals and careful records made of weight, pulse, blood pressure, and subjective complaints, while evidence of toxic effects was sought by general examination and reappraisal of urine, blood cell count, and basal metabolism. After each patient had been receiving one medicament or the other for about three months, the study was concluded, with 30 patients remaining—14 taking tablet A and 16 taking tablet B. We were then informed that A was phenmetrazine, 25 mg., and B the placebo.

Results

It was at once apparent that with phenmetrazine every patient lost weight. This was accomplished smoothly and consistently at an average weekly rate of 1.34 lb. (0.6 kg.) for the group. The average weight loss for all patients receiving phenmetrazine was 15.25 lb. (7 kg.). With the placebo, some patients lost and others gained, so that an average weight loss of 0.24 lb. (0.1 kg.) per week was obtained. The average weight loss for all patients receiving the placebo was 3.02 lb. (1.4 kg.) for the duration of the study; this provided a direct contrast to results with the active drug. Summaries of representative cases follow.

Case 3.—A 42-year-old male was given phenmetrazine. He had a 25-year history of grand mal seizures and marked obesity. His seizures were kept under control with use of diphenylhydantoin (Dilantin) and phenobarbital. He had been un
in many previous attempts to reduce. Physical
revealed an obese male 67 in. (170 cm.) tall and w
289 lb. (131 kg.). Blood pressure was 130/80 mm. H
rate was 76; urinalysis and complete blood cell co
normal; fasting blood sugar level was 140 mg. per 1
basal metabolic rate was +4%; uptake of radioactive
(I^{131}) was 39%; and an electrocardiogram showed o
ventricular premature contraction. The patient made n
plaints but between March 21 and April 4 administra
phenmetrazine was interrupted because irregularity of th
was noted and an electrocardiogram revealed the pre
ventricular premature contractions.

Table 1.—*Record of Weight, Pulse, and Blood Pressure for Patient in Case 3 over Period of Fifteen Weeks*

Date	Weight, Lb.	Pulse, Beats/Min.	Blood Pressure, Mm. Hg

6/ 6	259.5	72	120/80
6/20	256.75	72	120/80

Case 21.—A 55-year-old housewife was given placeb
had attended the clinic for many years and had a l
history of obesity, hypertension, and osteoarthritis. Sh
referred to endocrine clinic for weight reduction. P
examination revealed an obese female 62 in. (157 cm
and weighing 206.5 lb. (94 kg.). Blood pressure was 1
mm. Hg; pulse rate was 90; urinalysis and complete bloo
count were normal; blood cholesterol level was 160 m
100 cc.; I^{131} uptake was 25% and x-ray showed osteoar
of the spine and shoulders. With placebo there was no c
in the complaint picture. The patient had suffered fro
somnia for many years, and "reducing tablets" effecte
change.

Table 2.—*Record of Weight, Pulse, and Blood Pressu Patient in Case 21 over Period of Sixteen Weeks*

Patient gained weight

It is interesting to note that over one-half of the obese patients had diastolic hypertension. Nevertheless, there seemed to be no adverse effect from the drug. Each patient was examined and questioned carefully on revisits at two-week intervals. Blood pressures and pulse rates did not vary, and surprisingly few subjective side-effects were elicited. One patient receiving tablet A felt that her previous degree of insomnia became more severe, but a similar complaint was made by a patient taking tablet B. Nervousness, dry mouth, and dizziness, all of mild degree, were reported with tablet A, while one patient receiving tablet B developed indigestion.

Not included in this study, since there were no controls, were 20 patients treated with phenmetrazine in private practice. In almost every instance a marked anorexiant effect was noted, and side-effects were minimal. Only one patient felt a nonspecific sense of nervousness and discontinued use of the drug. Occasionally a complaint of dryness of the mouth and also a story of headache during the first day or two of therapy were encountered.

TABLE 6.—*Analysis of Findings in Two Groups of Patients Treated for Obesity*

Total weight loss, lb	216.25	50.25
Av weight loss, lb	15.25	3.02
Av. weight loss per wk,* lb	1.34	0.24
(Standard error of av)	(0.343)	(0.113)
Incidence of side-effects	4	2

* Average weekly weight loss for the phenmetrazine group was statistically significant at the 1% level For placebo group, it was of borderline significance at the 5% level The difference was also statistically significant at the 1% level

An analysis of the results of the clinical study is given in table 6. The total amount of weight lost by each patient and the average weekly weight loss were five times as great with phenmetrazine as with the placebo. Illustrating the effectiveness of phenmetrazine as an anorexiant, the average weight loss was 1.34 lb. per week, as compared with 0.24 lb. with the placebo.

Summary

Clinical investigation of a new anorexiant, phenmetrazine hydrochloride, was conducted in our endocrine clinic by means of a double-blind procedure. Thirty obese patients were treated with either tablet A or tablet B, with no special stress placed on diet. After three months the study was concluded and we were told that tablet A was phenmetrazine, 25 mg., and tablet B a placebo.

Patients who received phenmetrazine lost an average of 15.25 lb. (7 kg.) each, at a rate of 1.34 lb. (0.6 kg.) per week. Patients who received the placebo lost an average of 3.02 lb. (1.4 kg.) each, at a rate of 0.24 lb. (0.1 kg.) per week. Incidence of side-reactions and subjective complaints was negligible, and examination, including pulse, blood pressure, blood cell count, and urinalysis, showed no signs of toxicity. Phenmetrazine hydrochloride was found to be an effective and seemingly harmless anorexiant for routine therapy in obese patients.

625 Park Ave. (21).

The phenmetrazine used in this study was supplied
ludin by Geigy Pharmaceuticals, Division of Geigy Ch
Corporation, Yonkers, N. Y.

OBSTETRICIAN'S ROLE IN POSTPARTUM MENTAL ILLNESS

Mary A. White, Ph.D., Curtis T. Prout, M.D., Carl Fixsen, B.A.
and
Marvin Foundeur, M.A., White Plains, N.Y.

One hundred patients with postpartum mental illness were compared with a group of 100 female patients, matched for age and year of admission, who had been admitted to the same institution for mental illness not associated with childbirth. No significant difference in symptomatology was found. Postpartum mental illnesses are not a psychiatric entity; the term should be understood to refer simply to the usual psychiatric disorders but in the setting of childbirth. Current beliefs regarding etiology were found to need correction. The illness was not especially associated with first pregnancies; almost half of the patients had experienced childbirth before without recognizable mental illness. Among the most frequent precipitating factors were unstable marriages, long-standing maladjustment of the patient herself, immaturity of the patient, unstable family history of the patient, and the creation of new financial and other strains by the birth of the baby. The same factors were found important in determining the prognosis. The obstetrician's role includes early recognition of symptoms, use of nursing precautions to prevent suicidal and homicidal attempts, and use of a prognostic guide described by the authors. Textbooks of obstetrics need revision in the light of new facts about postpartum mental illness.

The results to be presented here derive from a recent study[1] of 100 consecutive patients with postpartum mental illness, admitted to the New York Hospital-Westchester Division between 1944 and 1952. Our purpose was an exploratory one, to discover what we could about the present nature of this reaction by comparing these patients with a control group consisting of 100 female patients admitted to this same hospital, matched for age and year of admission, but whose mental illness was not associated with childbirth. In presenting our data, we will compare them with a survey of this subject as given in current obstetrics textbooks[2] so as to provide the practicing obstetrician and future students with a summary of the present knowledge of this reaction and in the hope that future textbooks may correct certain impressions that seem to us to be out of date, inaccurate, or confusing.

The term "postpartum mental illness" was broadly conceived in our study to mean any mental illness in which childbirth was thought to be a major precipitating factor. "Postpartum" actually includes antepartum reactions, and the term is used solely because it is the common one.

A word, first, about the research to date regarding this reaction. There have been a number of studies (see references cited in our earlier article[1]), usually clinical reviews of cases, which have often reflected the special nature of the sample studied. Few investi-

Read before the Section on Obstetrics and Gynecology at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

gators[3] have employed any type of control group for evaluating the significance or results. Many of the points of disagreement found in both the reported research and in the textbooks may be due to generalizations from small and possibly biased samples. An example of this is Zilboorg's paper,[4] which stressed certain analytic interpretations and which has influenced the presentations in some textbooks. The careful reader finds it difficult to determine the exact nature of the populations studied or how these cases were selected, so any generalizations based upon so few patients, especially if they were all schizophrenic, would be questionable.

Definition

The obstetrics textbooks use confusing terminology in referring to mental illness associated with childbearing, such as puerperal insanity; gestational psychosis; confusional insanity; insanity of pregnancy, of labor, of puerperium, and of lactation; psychosis in pregnancy; toxic and infectious exhaustive psychosis; and postpartum psychosis.

One of the major reasons for confusing terminology has been the changing theories of causality. In the past, many of the postpartum mental illnesses were probably related to toxic, infectious, and exhaustive factors inherent in the medical problems of those times. With improved medical care, such conditions are increasingly rare. There has also been a trend away from organic diagnoses as psychiatry has come to recognize functional elements. Most recent authors agree that toxic, infectious, and exhaustive factors play a smaller and smaller role in the postpartum reactions. In an earlier study[5] at this same hospital of patients admitted between 1911 and 1923, 11 of the 72 patients studied had diagnoses of delirium. In our present study, none of the 100 patients had an organic diagnosis, which reflects the decreasing role of organic reactions.

We recommend dropping terms such as puerperal insanity, confusional insanity, and toxic psychosis from future textbooks and limiting ourselves to the term "postpartum mental illness," since it is the current psychiatric term, or else to "gestational mental illness." Either term is free of organic implications, of the undesirable term "insanity," and of the implication that only a psychosis can occur.

Incidence

Depending upon the text one reads, the incidence of postpartum mental illness ranges from one in 400 to one in 1,000 pregnancies. The incidence of mental illness in all pregnancies is probably impossible to compute accurately, because there is no one reliable observer present throughout the entire period of possible onset. Hospital statistics and incidences reported by obstetricians are probably low, since many of these illnesses occur after the last obstetric contact, assuming that to be usually six weeks after delivery. In our present study 89 patients had no recognizable symptoms until after delivery. Of these 89, 55 showed symptoms within six weeks, but 34 showed symptoms well after six weeks of delivery. Let us assume that the 55 would be known to their obstetricians; this leaves 34 of the 100 patients studied who developed symptoms well after the last regular contact with their obstetrician. This means that as many as one-third of all such cases may be overlooked by obstetric sources, suggesting that any estimated incidence would need to be corrected to approximately one in 300 up to one in 750. Even this estimate may miss patients who do not receive psychiatric attention, who are not hospitalized, and who are in no way known to persons who compile such estimates. We recommend that any figures of incidence given in a text or lecture be treated as the vaguest of estimates until such time as reporting is more reliable.

As for the number of women with postpartum mental illness compared to all female patients admitted to a psychiatric hospital, there is a similar confusion. Rates cited in the textbooks reviewed were 2%, 5%, and 10% of all females admitted because of mental disease. Figures will differ depending on how one defines the postpartum illness. In our recent study, our definition was as broad as was reasonably possible, so the 5.3% obtained for women with this illness compared to all females admitted to this hospital during the same time interval could be considered the upper limit for such percentages.

The whole question of incidence needs to be clarified. Let us assume that the age span in women for a functional mental illness requiring hospitalization is roughly from 16 to 60 years, which is a span of 44 possible years. Let us further assume that the average number of children born per mother was roughly 3.7 children in 1950 for the population as a whole. We will allow 9 months of pregnancy and six weeks post partum for each child, which means that each woman spent, in those 44 years, about 39 months directly involved in the act of childbearing. What are the chances for any mental illness occurring during these childbearing months? If we divide 44 years into 39 months, we get about 7%, which would be the incidence simply by chance alone, with no causal relationship implied. It seems to us that 7% is a generous estimate of the expected incidence among females admitted for psychiatric reasons. Again, we caution future authors from placing reliance upon any such figures because of problems in definition and because of the varying admission policies of psychiatric installations. With the current trend toward increased outpatient psychiatric care and the use of tranquilizing drugs, these figures may change.

Etiology

According to the textbooks, the etiology of these illnesses includes faulty elimination, insomnia, toxemia, illegitimate pregnancy, poor heredity, unstable premorbid personality, frigidity, homosexuality, sepsis, fear of responsibility of motherhood, a first pregnancy, unknown organic factors, masturbation, financial worries, a male child, disappointment in the sex of the child, and previous mental illness.

Our present knowledge of the etiology of the postpartum mental illnesses is similar to our knowledge of most other mental illnesses. There are four general types of explanations: organic factors, heredity, personality predisposition, and environmental influences. It seems reasonably well accepted now that organic factors derived from childbirth itself have a relatively minor influence.[6]

We can report no specific cause for the postpartum mental illnesses that emerged from our study of 100 such patients. There would seem to be as many different constellations of contributing factors as there are patients studied. But approximately 30% of these postpartum patients had had a previous attack of mental illness. This is almost exactly the same percentage found in the control group. In other words, the postpartum patient is like any other female patient of the same age admitted to this hospital in respect to previous mental instability. Approximately the same percentage, 20% to 30%, of both groups had also had a previous admission to a mental hospital. Tetlow's recent findings [3b] are in agreement on this point.

As for the sex of the child, our study did not demonstrate this as a factor. Only 11 of our 100 patients reported disappointment in the sex of the child. Since 48 of the infants born were male, 51 were female, and one was stillborn (sex not given), there would seem to be no encouragement for believing that the sex of the child is an etiological factor.

Some authors have felt this illness is primarily associated with first pregnancies. It seems to us that this partially a result of a statistical misunderstanding. bviously there are more first-born persons in the population than of any other sibling rank. One should expect the incidence of all these illnesses to decrease with the birth rank of all children, since the actual number of such pregnancies must also decrease with the rank of the child born. In our study, 57 patients reacted to their first-born, 26 to their second, 13 to their third, and 4 to their fourth child. It is difficult to obtain figures for a comparable normal population in order to test the significance of this frequency, although Vislie [3c] made such a comparison and concluded that women going through their first pregnancies were more susceptible. What was significant, perhaps, in our study was that almost one-half of the patients reacted to a later child rather than to their first child. Almost half had experienced childbirth at least once without a recognizable mental illness. It would not be wise to infer that this illness does not occur after one stable pregnancy, but it is possible that the illness occurs more often in first pregnancies. The obstetrician might remember that almost one-half of these illnesses which he will see will occur in multiparas.

As for physical complications which might have caused undue stress, a review of these 100 histories failed to reveal unusually difficult pregnancies or deliveries, as reported by the attending obstetrician or by the patient's family. Tetlow's controlled study [3b] of 67 patients also showed no significant frequency of physical complications.

In the psychiatric literature, reference has been made to the frequency of this illness among patients of Jewish background. This seems to be another statistical mishap. One must compare these patients to a matched control group from the same hospital, since the population of a hospital may reflect ethnic patterns of its area. When we made such a comparison, no significant incidence was found for any one religious group. Abnormal sexual behavior, such as frigidity, homosexuality, or masturbation, was not outstanding in our group nor in Anderson's.[3a]

The precipitating factors which impressed us in our group of patients were these, in order of frequency: (1) unstable marriage; (2) long-standing maladjustment of the patient herself; (3) immaturity of the patient; (4) unstable family history of the patient; (5) birth of the baby creating considerable extra responsibility upon the patient, particularly financial; (6) baby not wanted by wife or her husband; (7) physical illness of mother or the baby, including extreme fatigue in caring for a sick baby; (8) unfavorable situation at home after delivery, such as poor living conditions, in-law friction, death of a relative, or husband losing his job; and (9) traumatic situations, such as the suicide of a relative or witnessing a tragic death. There were additional factors that were hard to classify, such as a fearful reaction to childbirth based on ignorance, or low mentality.

It seems to us as well as to others [7] that what precipitates such an illness can be a combination of many things, rather than one simple factor. There is the patient's basic stability, the stability of the marriage itself, the setting into which the baby is born, plus a combination of circumstances to which the patient might have been especially vulnerable. The arrival of a child into such circumstances can set off complicated reactions in the total life situation which are due not to the symbolism of childbirth as much as to a difficult life situation faced by a somewhat unstable person.

We have, it will be noted, referred to "precipitating factors" rather than to etiological factors. This is due to our reluctance to posit causal factors without the assurance that we are correct. The cause or origin of a disease is something we need to have correct, particularly when we are educating future physicians.

Onset

Some texts say symptoms often occur in the first trimester, still others say not until after delivery. Some say that depressions begin during pregnancy, whereas schizophrenic reactions appear during pregnancy and labor; the onset may be slow or sudden. If the onset follows delivery, some say this happens in the 10th to 14th day, some say the 1st to 14th day, and some say up to the end of the second year.

The data from our study support few of these statements. Only 11 of our 100 patients showed recognizable symptoms during pregnancy, these occurring on the average between the fourth and fifth months, but an average is of little value with so small a number. The remaining 89 showed symptoms after delivery, which suggests that this is when the bulk of reactions are to be expected.[8] Of these 89 reactions, 55 had their onset within six weeks of delivery, with a mean onset of two and one half weeks. (Only 21 of these patients showed symptoms within the first week, when presumably they were still in a general hospital. This means that only about 20% of these reactions would be seen today while a patient was in the hospital or on an obstetrics service.) As was stated earlier, the balance, 34 patients, had their onset after six weeks, with an average of some four months after delivery. This average was not distorted by a few extreme cases. This suggests that one in three cases of postpartum disease, as defined here, had its onset well after the patient's last regular obstetric contact.

Two questions remain about onset: first, is there a typical time of onset for any one type of illness, and, second, is time of onset related to prognosis? Our data indicate that most of the psychoneurotic and manic-depressive disorders occur after delivery, about half of these within six weeks and half later. The schizophrenic patients, as a group, tended to have a more sudden onset after delivery, but the interval ranged up to 10 months. In our follow-up study, we found that the schizophrenic patients, as a group, did less well than either the psychoneurotics or manic-depressives, so we infer that a sudden onset after delivery is not related to a good prognosis.

Symptoms

The symptoms described in the textbooks cover almost everything, and even for someone familiar with mental disorders it would be most difficult to recognize an illness from such descriptions. The symptoms are said to include insomnia, irritability, anxiety, depression, delusions, neurotic symptoms, excitement, hallucinations, hostility, homicidal threats, suicidal attempts, restlessness, mood swings, and suspicion. These might describe the symptoms of the population of any psychiatric hospital.

It seems to us that the whole topic of symptoms is closely related to a discussion of diagnoses, unless one believes that the postpartum mental illnesses are a diagnostic entity in themselves. One of the major findings of our research has been that the postpartum mental illnesses are not a psychiatric entity; childbearing is no different from any other situation to which people can react with mental disorders.[9] To every major change in life, such as adolescence, marriage, childbirth, promotion, or aging, there are some people who react abnormally. To us, postpartum mental illness is merely a term to refer to the illness of those patients who develop the usual psychiatric disorders, but in the setting of childbirth. A cause-and-effect relationship between childbirth and mental illness is not implied,[3a] only a temporal relationship. The symptoms of these illnesses therefore should be discussed in connection with the types of disorders that occur.

Types of Disorders

One finds a multitude of types of disorders described in the textbooks, depending upon the author's theoretical point of view and upon the adequacy of his review of previous research. There are those who stress depressions, confusional states, or schizophrenia. Some type the reaction according to its time of onset.

This topic would be clarified greatly if the textbooks referred to research in which the types of postpartum disorders have been found to be quite like those occurring in psychiatric patients of the same age and sex.[10] In our study, we compared the diagnoses of the 100 postpartum patients with those of our control group. There were no significant statistical differences between these two groups in the frequency of psychoneurosis, schizophrenia, or manic-depressive illnesses. The significant point would be that the major mental disorders of this age group of women occur with the same distribution in the postpartum setting as they do in any other setting.

If we accept this finding, then any description of types of illnesses and their symptoms should follow the descriptions of these disorders given in any up-to-date psychiatric textbook. The future obstetrician would be well advised to recognize the symptoms of the major functional disorders as they are currently taught in psychiatry. Psychiatric consultation might be a helpful step for the practicing obstetrician whenever there is any question as to the nature or severity of the reaction.

Considerable emphasis has been placed in the textbooks upon suicidal and homicidal risks among these patients. Current research, including our own and Vislie's,[3c] would support the idea that suicide is a sufficiently common risk to alert the obstetrician that close nursing observation and safety precautions for these patients are a wise move, at least until such time as the patient is under psychiatric treatment or sufficiently improved.

The homicidal risk is another matter. Many postpartum patients express hostility toward their newborn infants, and often toward their husbands, but evidence is scanty regarding the frequency of infanticidal attempts. We cannot report a homicidal attempt in any of our 100 patients, nor did Anderson[3a] or Vislie.[3c] It may be that, with earlier recognition and treatment of these patients, the opportunity has been decreased. In planning nursing care, precautions against hostile acts should be observed. If a patient is so disturbed as to threaten homicide, it seems reasonable to expect that the physician will have already sought psychiatric consultation.

Treatment

The topic of treatment is usually cited briefly in the textbooks except for advice as to the use of electroshock treatment and hospitalization as indicated. Usually psychiatric consultation is suggested. The subject of early detection might profit from amplification, but this depends in turn upon the author's familiarity with the psychiatric disorders and their symptoms. The obstetrician needs to be aware that postpartum mental illnesses can take the form of any functional mental illness and that therefore any symptom can have significance, from tension, depression, and insomnia to flagrant hallucinations. Reassurance by the obstetrician, as long as it is successful, is the treatment most often suggested in the textbooks. We would argue for increased emphasis upon early detection and careful observation.

In discussing treatment, since the patients in our study were all hospitalized, we must limit ourselves to psychiatric hospital treatment. These 100 patients spent an average of seven months in this hospital, which was a significantly shorter hospitalization than for the controls. Some received electroshock treatment, but all received psychotherapy as well as program therapies. There was no unique plan of psychiatric treatment that differentiated them from other patients. However, one-third of these postpartum patients left the hospital against advice, prior to the time the hospital staff felt that a good level of recovery had been reached. This was a significantly greater amount than in our controls. Those who left the hospital against advice stayed an average of 4.4 months, some 3 months less than the total postpartum group. This raises the question: Does leaving the hospital against advice, prior to the conclusion of treatment, affect the patient's chance of recovery? In our study, it did. Those who left the hospital too soon had a significantly lower level of adustment upon follow-up than did those who left with the staff's approval. This may be due to the shorter hospitalization or possibly to the pressures within a family situation which caused the patient to leave as she did.

To date, our knowledge of treatment for these mental disorders is like that for other mental disorders. No specific treatment is yet known. Psychiatric hospital treatment includes psychotherapy, planned activities, and good nursing care. Electroshock treatment follows the indications found in any other patient. (Tranquilizing drugs had not been in use at the time our patient group was studied.)

Prognosis

In discussing prognosis, we will omit the organically induced disorders, which we think to be infrequent these days, and concern ourselves only with the functional disorders. The textbooks vary considerably regarding the prognosis for individual types of illness, but most authors feel the over-all prognosis is good, a point with which we agree wholeheartedly.

The follow-up study of our 100 patients was carefully done, with detailed information obtained on 9 of the 100 patients. The follow-up period following hospitalization ranged from one to nine years, averaging four years. The details of this study are published elsewhere,[1] so only the final results will be give here. Seventy-two of these patients had achieve a reasonable level of adjustment some four years aft hospitalization; of these, 57 were apparently reco ered. The balance were making a marginal adjus ment, were still in treatment, or were in a ment hospital. One could restate this to say that three o of four made a reasonably good recovery and thr out of five were fully recovered. From what w know of similar hospitalized groups, this can be co sidered a good recovery rate.

The types of disorders varied in their prognos The manic-depressive and psychoneurotic groups d somewhat better than the schizophrenic group, whi is consistent with our present knowledge of the illnesses. But one must be cautious of group averag because many individual schizophrenic patients d extremely well and also because diagnosis itself is t variable to put much faith in prognosis based upon Our data do not substantiate the opinion that t later the onset the worse the prognosis or the mo excited and confused the patient the better the pro nosis.

Many workers in the mental health field look f reliable prognostic signs, and we were no exceptio Our data indicate a quick rule of thumb for progno which seems to be reasonably accurate. When an o stetrician has a patient who is to be hospitalized f a postpartum mental illness, a good psychiatric histo is his most reliable guide. We would ask him to revie the psychiatric history for the following major poin (stated briefly): (1) long-standing maladjustment the patient, (2) family history of mental illness, (psychological immaturity of the patient, and (4) u stable marriage.

If the obstetrician finds none or only one of the four factors, then he can feel quite confident abo the ultimate prognosis after psychiatric hospitaliz tion. Of the 31 patients in our study who showed non or only one of these factors, 28 made an excellen recovery and the remaining 3 made a fair recovery. In other words, 9 out of 10 such patients who had none or one of these factors made an excellent recov-

y. There was considerable variability in the recovery
tes of patients with two or more factors, making
ediction based upon the presence of two or more
ctors not reliable. The advantage of this prognostic
ıle of thumb is that it is based on data available at
ıe time of onset, allowing the obstetrician to guide
ıe patient's family as to the future outlook when the
atient's illness has just begun.

As for future pregnancies, most authors are pessi-
ıistic because of the possibility of further mental
lness. Some speak of therapeutic abortion for this
eason. We do not share this degree of pessimism,
nd similar optimistic figures regarding both prognosis
nd future pregnancies have been found recently by
Madden and others.[11] There were 27 subsequent preg-
ıancies among 22 of our patients, and only 3 patients
eacted with a recurrence of their mental illness. From
his small sample, one might infer that the chances
are that one in seven patients will experience mental
illness associated with a subsequent pregnancy. Of
course, there may have been some patients who avoided pregnancy for mental health reasons, so such figures are only the roughest of estimates. In the group studied in Norway,[3c] several abortions were performed, but of those women bearing children, 12 of 15 had no untoward mental reaction. The patients who aborted may have been poorer mental risks. It would seem however that the risk of recurrence is not so great as to preclude future pregnancies.

Summary

A study of 100 patients with postpartum mental illness and their control group, and a review of the recent literature, would suggest to the obstetrician the following points of current information: 1. The postpartum or gestational mental illnesses are not a psychiatric entity in themselves but instead are the typical functional mental illnesses found in women of this age. 2. The relation between childbirth itself and mental illness is not thought to be causal, nor is any one etiological factor demonstrated. 3. The birth of a child is thought to be a final precipitating factor in a somewhat unstable person facing a total life situation to which she may be vulnerable. 4. Although first pregnancies may be frequently associated with postpartum mental illnesses, approximately one-half of all such patients seen by the obstetrician may be multiparas. 5. The onset is most likely to follow delivery, with one-third showing symptoms some four months after delivery, well after their last regular obstetric contact. 6. The incidence of these reactions in all pregnancies is reestimated to be from one in 300 to one in 750, whereas the incidence among all female psychiatric admissions is reestimated to be from 5 to 7%. 7. The prognosis for these disorders, following hospitalization, is good.

The obstetrician's role in these disorders might include (1) early recognition of psychiatric symptoms, which will be those typically found in any of the major functional disorders; (2) after recognition, initiation of careful nursing precautions against suicidal and homicidal attempts until psychiatric consultation is obtained; (3) an estimate of a patient's recovery after hospitalization by use of a brief prognostic guide; (4) the recommendation to the patient and her family not to terminate hospitalization against the staff's advice, since this has been associated with a poorer prognosis; and (5) diminished pessimism that future pregnancies are associated with further mental illness.

The authors of obstetrics textbooks should clarify the presentation of postpartum mental illnesses in future editions.

PREANESTHETIC USE OF ATROPINE AND SCOPOLAMINE IN PATIENTS WITH GLAUCOMA

Herman Schwartz, M.D., Andrew de Roetth Jr., M.D.
and
Emanuel M. Papper, M.D., New York

In patients with glaucoma some confusion exists regarding the parenteral use of atropine and scopolamine as preanesthetic medication for nonocular surgery. This study suggests that there is no danger in using the belladonna drugs intramuscularly for preoperative medication. A single dose of atropine sulfate (up to 0.6 mg.) and scopolamine hydrobromide (up to 0.6 mg.) may be used. Pilocarpine hydrochloride (1 to 2%) or physostigmine salicylate (0.25% to 1%) should be instilled into the conjunctival sac to produce miosis to counteract the potential mydriatic effect of the belladonna drugs and the anesthetic agents.

Proper preanesthetic medication before general anesthesia includes the parenteral use of a belladonna drug such as atropine or scopolamine. These drugs diminish salivation and tracheobronchial secretions during the induction and maintenance of general anesthesia. In patients with glaucoma, some confusion exists regarding the parenteral use of atropine and scopolamine when an operation unrelated to the eye is necessary. Most of the data in the literature are concerned only with the ophthalmic effects of locally and orally administered belladonna drugs.[1] It is necessary to know with certainty the effects of these drugs upon the eye when administered by injection to glaucomatous patients. It is unreasonable to continue to apply incomplete and inconclusive evidence[2] which has resulted in improper preparation of the patient with glaucoma for surgical treatment of other parts of the body.

Therefore, a study was undertaken to determine the ocular effects of atropine and scopolamine, administered intramuscularly (in doses of 0.4 to 1.0 mg.) to patients with acute and chronic glaucoma. The effects of these drugs on the intraocular pressure and pupillary size changes were measured and compared.

Method

Fourteen patients were studied, eight with chronic simple (open-angle) glaucoma and six with acute (angle-closure) glaucoma. The patients with acute glaucoma were in a state of remission, and five had been treated previously with unilateral iridectomy. Local miotic therapy was stopped, and no medication of any kind was permitted during the 48 hours prior to the study. Two drops of 0.5% tetracaine hydrochloride, which does not influence pupillary size, were instilled into each eye for corneal anesthesia. The intraocular pressures were measured with a Schiøtz tonometer.

Four patients with chronic simple glaucoma and three with acute glaucoma were given atropine sulfate (0.5 to 0.6 mg.), intramuscularly, and the same number in each group were injected intramuscularly with scopolamine hydrobromide (0.4 to 1.0 mg.). The intraocular tensions were measured at 20-to-30-minute intervals for two hours. The average and the range of these measurements for each patient appear in tables 1 and 2.

In 10 subjects the diameter of the pupil was also measured with a millimeter ruler. In five of these subjects both eyes were studied. In the other five it was only possible to measure one eye, since the other eye had had an iridectomy. Therefore, a total of 15 eyes were studied.

Results

Chronic Simple Glaucoma—Atropine (Table 1).—There were no changes or a fall in intraocular tension in seven eyes after the injection of atropine. Only in one eye (left eye, subject 3) was there a rise, and that was a maximum of 3 mm. Hg. Subject 1, during one measurement, exhibited a decline of 8.6 mm. Hg in the left eye.

Chronic Simple Glaucoma—Scopolamine (Table 1).—There was no change in intraocular pressure in four eyes after scopolamine. In two eyes (left eye [O. S.], subject 5; right eye [O. D.], subject 6) there were small rises. These changes appeared to be of no importance to the welfare of the eyes. Subject 8 was not included in the compilation of the averages because the dose of 1 mg. of scopolamine is greater than that usually used for preanesthetic medication. This patient exhibited a significant fall in intraocular pressure, the pressure at one point falling 9.8 mm. Hg. This may have been the result of the sedative effect of a relatively large dose of scopolamine.

Acute Glaucoma—Atropine or Scopolamine (Table 2).—There were no significant differences in intraocular pressure in patients with acute glaucoma after the injection of atropine or scopolamine. There was a fall

tension in 10 eyes and small rises in tension in 2). S., subject 10; O. D., subject 12). The falls in traocular pressure were more frequent and on the erage greater in the patients with acute glaucoma an in those with chronic simple glaucoma following e injection of therapeutic doses of the belladonna rugs. However, in neither group was there a single gnificant rise. Eleven of the 15 eyes in which upillary sizes were measured exhibited slight mydatic changes ranging up to 1 mm. in diameter and veraging 0.5 mm. Four pupils did not change at all.

Comment

Glaucoma is manifested by a rise in the intraocular pressure above normal levels. In the acute type this condition is aggravated by a dilated pupil, which permits the iris to interfere further with the outflow of aqueous humor at the canal of Schlemm.[3] Atropine or scopolamine instilled into the conjunctival sac are classic mydriatic drugs [1a] and are to be avoided in patients with glaucoma. Acute attacks of glaucoma have also been reported from the oral use of large doses of belladonna in the treatment of gastrointestinal disturbances.[1b] However, only one case can be found in the literature where preanesthetic injection of atropine in reasonable dosage may have contributed to the erroneous belief that parenterally given atropine and scopolamine are contraindicated for preanesthetic medication in patients with glaucoma.[2]

This study strongly suggests that there is no danger in using the belladonna drugs intramuscularly in the doses studied in patients with glaucoma who are being prepared for nonocular surgery. It does not suggest in any way that appropriate medical therapy for the glaucomatous patient can be abandoned. Pilocarpine hydrochloride (1% to 2%) or physostigmine salicylate (0.25% to 1%) instilled into the conjunctival sac should be given to produce miosis.[4] They also counteract the potential mydriatic effect of the belladonna drugs and the anesthetic agents.[4] Since a patient with glaucoma usually is treated with one of these drugs, preoperative and postoperative use of the same preparation can be continued.

Intramuscular doses of morphine sulfate (up to 15 mg.) cause constriction of the pupil as well as a fall in the intraocular pressure.[5] Barbiturates (given orally or parenterally) also lower the intraocular tension in patients with glaucoma.[6] The use of these drugs may therefore be incorporated in the preanesthetic medication if not contraindicated for nonocular reasons.

Summary

The effects on intraocular tension produced by the intramuscular injection of therapeutic doses of atropine sulfate and scopolamine hydrobromide were studied in 14 subjects (28 eyes) with acute and chronic simple glaucoma. Both drugs produced small rises in tension in only 5 of the 28 eyes. These increases are insignificant. Twenty-three eyes exhibited either no change or a fall in the intraocular pressure. Slight mydriatic changes were noted in 11 of the 15 pupils measured. The pupil never increased in diameter by more than 1 mm.

The safety of a single dose of parenterally given belladonna drugs for preoperative medication in glaucomatous patients was clearly established. The maintenance of topical instillations of pilocarpine hydrochloride (1% to 2%) or physostigmine salicylate (0.25% to 1%) into the conjunctival sac in the preoperative and postoperative periods is recommended. Morphine sulfate and the barbiturates may be used (for premedication and during general anesthesia) in the safe management of patients with glaucoma for extraocular operation.

THE INFLUENCE OF VARIOUS CLINICAL DISORDERS AND DRUGS ON EXCRETION OF UROPEPSIN

Leo J. Corazza, M.D.

and

Ralph M. Myerson, M.D., Philadelphia

In order to determine the amount of uropepsin excreted every 24 hours by normal individuals as well as by those with diagnosed disorders, 960 uropepsin determinations were performed on 280 patients. There is a significant fluctuation in daily excretion by the same individual and a marked degree of overlapping of results between normal individuals and patients with duodenal and gastrointestinal lesions. Both physical and emotional stress may have an effect on uropepsin excretion. It is felt that these variables make the uropepsin excretion an unreliable test in routine gastrointestinal diagnosis.

The existence of a proteolytic enzyme in the urine has been known since 1861. In 1947, interest in this enzyme, usually referred to as uropepsin, was stimulated by Bucher's excellent review,[1] and since that time a considerable amount of literature has appeared. It has been demonstrated that uropepsin originates from the peptic cells of the stomach as an endocrine secretion and that urinary and plasma pepsinogen are identical with crystalline pepsinogen obtained from the stomach.[2] Uropepsin is found in the urine in amounts equal to about 1% of the gastric peptic output.[2b]

While there is agreement on the fundamental aspects of uropepsin excretion, opinions regarding the application of uropepsin assay to clinical problems and diagnosis differ widely. In the present study, 960 uropepsin determinations were performed on 280 patients. Our purpose was to determine the amount of uropepsin excreted by normal individuals and to assess the influence of disorders of the gastrointestinal tract, psychic stimuli, gastric surgery, pernicious anemia, and drugs on uropepsin excretion.

Method of Assay

In most instances, three or more 24-hour specimens were analyzed to establish the mean output in a given case. The procedure employed was a modification of the methods described by Bucher[1] and Anson and Mirsky[3] as reported by Gray and his associates.[4] A 1-ml. aliquot of acidified (pH 1.5), diluted (4:5) urine from a 24-hour specimen was incubated 5 ml. of 2% acidified (pH 1.5) hemoglobin subs at 37 C for 30 minutes. The reaction was termin with 10 ml. of 0.3*N* trichloroacetic acid and filt Tyrosine-like (phenol-positive) compounds prese the filtrate, resulting from the proteolysis of the h globin, were determined by use of the Folin-Cioc method.[4A]

A zero time control (blank) consisting of trich acetic acid-inactivated urine, and hemoglobin employed with each individual test to compensa chromogenic substances present in the urine and strate. Tyrosine standards (256, 128, and 64 mc milliliter) and reagent blanks were employed for

ies of determinations. The results are expressed as its of uropepsin activity per 24 hours. One unit of opepsin activity is that amount of enzyme which ould release an equivalent of 0.04 mg. of tyrone-like compounds during a 30-minute incubation riod at 37 C.

Results

The results of uropepsin determinations in the major roups studied are shown in the figure.

Normal Uropepsin Excretion.—The mean 24-hour opepsin excretion of 93 normal subjects without emonstrable gastrointestinal disease was 3,556 units, ith a standard deviation of ±1,265 units. There was treme variation in uropepsin output, which ranged om a low of 242 units to a maximum of 12,825 units. f the individuals studied, 64.5% had an output in the nge of 1,000 to 4,000 units. Daily 24-hour uropepsin utput was studied in four normal individuals during -to-10-week periods. Wide variations in daily excreon were noticed, despite the absence of any obvious ctors to produce such changes.

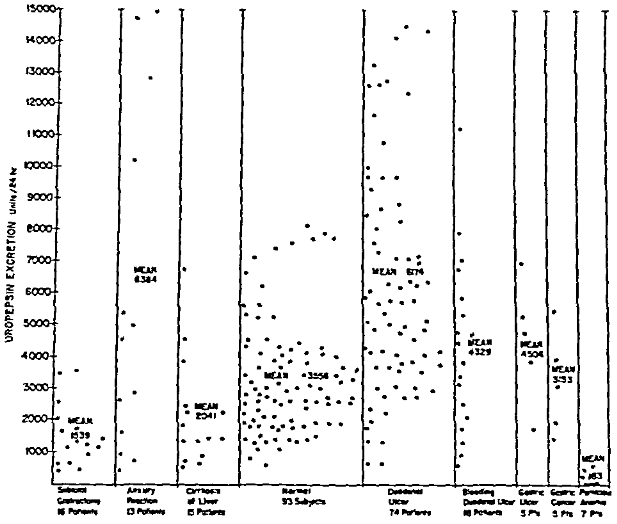
Excretion in Ulcer and Cancer Cases.—Seventy-four atients with proved duodenal ulcers had a mean 24-our uropepsin output of 6,147 units, with a standard eviation of ± 3,773 units. Again, both a wide indiidual variation and day-to-day fluctuation in the same atient were noted. During the course of ulcer therapy nd healing, no significant changes in uropepsin exretion were noted. The mean 24-hour uropepsin excreion of 18 patients with proved bleeding duodenal lcers was 4,329 units, with a standard deviation of ± 2,630 units. Extreme fluctuations in uropepsin exretion were again noted. Only five patients with roved benign gastric ulcerations were studied. Their mean 24-hour excretion of uropepsin was 4,506 units. Five patients with proved cancer of the stomach had a mean 24-hour uropepsin excretion of 3,153 units.

Excretion in Cases of Pernicious Anemia.—Seven patients with pernicious anemia had extremely low excretions. Uropepsin was absent in four cases, and in the other three cases the mean excretion was 409 units. There was no change in uropepsin excretion after the use of cyanocobalamin (vitamin B_{12}) and clinical remission. One patient presented a clinical picture resembling exogenous cyanocobalamin deficiency. After cyanocobalamin therapy in this patient, the uropepsin excretion rose to normal levels despite the persistence of histamine anacidity. In two patients with histamine anacidity but who were otherwise apparently normal, uropepsin excretion was within normal limits. The pH of the gastric contents in these patients was not determined. One patient with posterolateral sclerosis and achlorhydria, without, however, the hematological manifestations of pernicious anemia, had a 24-hour uropepsin excretion of 143 units. There was no increase in excretion during either cyanocobalamin or corticotropin therapy.

Excretion in Cases of Cirrhosis of the Liver.—The mean 24-hour uropepsin excretion in 15 patients with Laennec's cirrhosis of the liver was 2,014 units, with a standard deviation of ± 1,662 units. In two patients with combined duodenal ulcer and cirrhosis of the liver, uropepsin excretion tended to be high (5,800 and 6,800 units).

Excretion During Anxiety State.—Thirteen patients with the diagnosis of acute anxiety state had a mean 24-hour uropepsin output of 6,384 units. None of these patients had gastrointestinal symptomatology or radiologically demonstrable gastrointestinal disease.

Excretion in Cases of Subtotal Gastrectomy.—Sixteen patients with subtotal gastrectomies had 24-hour uropepsin excretions varying from 481 units to 3,543 units, with a mean excretion of 1,539 units and a standard deviation of ± 323 units. To minimize the effect of any "alarm" reaction, all excretion values were obtained at least one week after the patient had undergone surgery. There was no apparent relationship between the amount of stomach removed and the postoperative uropepsin excretion, nor could a definite relationship be established between preoperative and postoperative levels.



Uropepsin excretion in normal subjects and patients with gastrointestinal disorders, anxiety reaction, and pernicious anemia.

Miscellaneous.—No pattern of uropepsin excretion could be established for a miscellaneous group of patients with gastrointestinal disorders including regional ileitis, acute pancreatitis, cholecystitis, acute appendicitis, carcinoma of the large intestine, or diverticulitis. Three patients with chronic ulcerative colitis had 24-hour uropepsin excretions varying from 5,800 to 7,500 units with a mean of 6,700 units. Three patients with acromegaly excreted normal amounts of uropepsin.

Effects of Drugs.—Attempts to decrease the uropepsin excretion of patients with duodenal ulcer with anticholinergic drugs were unsuccessful. Atropine, methantheline (Banthine) bromide, and propantheline (Pro-Banthine) bromide were given orally in doses sufficient to produce dryness of the mouth and/or visual blurring. No significant change in uropepsin excretion was noted. Six patients with duodenal ulcers were treated with reserpine given orally in doses of 2 mg. daily. No significant changes in uropepsin excretion resulted.

In an attempt to alter the renal excretion of uropepsin, probenecid (Benemid), 2 Gm. daily, was administered to six patients. There was no effect on the excretion of uropepsin. Neither carinamide nor acetazolamide (Diamox) altered the excretion of uropepsin. Corticotropin was administered to 10 patients and resulted in an average increase of 75% in the uropepsin excretion. As long as three weeks may be required to achieve a maximum response to corticotropin. No increase occurred in two patients with pernicious anemia who received corticotropin. Testosterone had no effect on uropepsin excretion in two patients.

Comment

In our experience, the determination of the 24-hour uropepsin excretion has limited clinical application. There is a significant fluctuation in daily excretion by the same individual and a marked degree of overlapping of results between normal individuals and patients with duodenal and gastrointestinal lesions. This is apparent from the high standard deviations. Both physical and emotional stress may have an effect on uropepsin excretion. An example of this is demonstrated by the elevated levels in the majority of the patients with anxiety reactions. It is felt that these variables make the uropepsin excretion an unreliable test in routine gastrointestinal diagnosis. A similar view has been expressed by others.[5] Some investigators,[6] however, feel that the test has a definite place in the differential diagnosis of gastrointestinal disorders.

The complications of peptic ulcer such as hemorrhage do not appear to alter the uropepsin excretion. The presence of high levels of uropepsin excretion in gastrointestinal bleeding favors the diagnosis of peptic ulcer rather than esophageal varices, since the excretion of uropepsin tends to be low in cases of cirrhosis of the liver. In the present series, however, several patients with proved bleeding duodenal ulcers had low levels of uropepsin excretion.

Subtotal gastric resection tends to be followed by a decrease in the average uropepsin excretion. The decrease does not appear to be proportional to the amount of stomach tissue removed. Levy and Levine[7] have recently reviewed the subject of uropepsin excretion after gastrectomy.

An absence of or marked decrease in uropepsin excretion has been consistently noted in patients with pernicious anemia. This renders the test a valuable adjunct in the diagnosis of this disease. It may be of particular help in differentiating pernicious anemia from other macrocytic types of anemias.[5a]

An increase in the excretion of uropepsin following the administration of corticotropin has been a fairly consistent finding.[8] The increase is probably mediated through a humoral mechanism involving the hypothalamic-pituitary-adrenal-gastric axis that is independent of the vagus nerve.

Although anticholinergic compounds had no effect on uropepsin excretion in the present study, there have been reports[9] of a decrease during the use of these drugs. Balfour[10] found an an increase in uropepsin excretion during testosterone administration. We found no change in amount of uropepsin excretion in two patients treated with testosterone, and also no effect from oral use of reserpine, probenecid, acetazolamide and carinamide.

Summary

Nine hundred sixty uropepsin determinations were made on 280 patients, both without demonstrable disease and with disorders of the gastrointestinal tract, cirrhosis of the liver, anxiety states, subtotal gastrectomies, and pernicious anemia. Because of considerable variation in the daily uropepsin excretion and the degree of overlapping between normal values and those in patients with demonstrable gastrointestinal disease, it is felt that the test is of little value in differential diagnosis. Uropepsin was absent or low in seven patients with pernicious anemia. The assay may be a valuable diagnostic aid in certain cases of macrocytic anemias. Corticotropin caused a significant increase in uropepsin excretion. The use of other drugs (acetazolamide [Diamox], probenecid [Benemid], carinamide, and testosterone) had no apparent affect on uropepsin excretion.

CLINICAL NOTES

TWO NEW MODIFICATIONS OF THE ENDOTRACHEAL TUBE

Frank Cole, M.D., Lincoln, Neb.

The practice of endotracheal anesthetization not infrequently imposes two problems: easy insertion of the tube, for which exact control of the distal end of the tube is needed and is rarely provided, and the leaking inflatable cuff. In an attempt to solve both problems, I offer two devices, the threaded endotracheal tube and the double-cuff endotracheal tube.

Threaded Endotracheal Tube

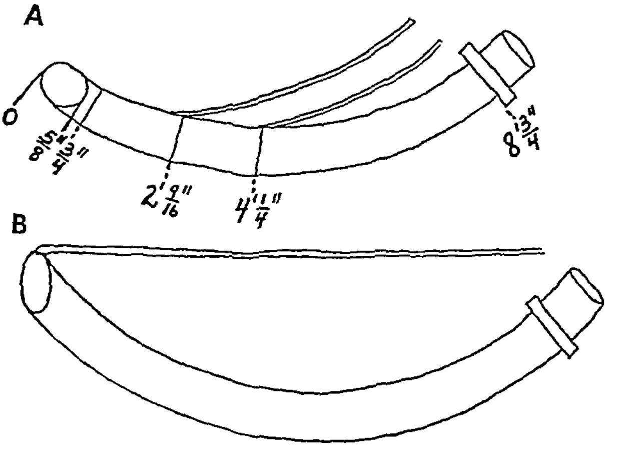
With the use of a simple paper-punch, a small hole is made near the end of the tracheal tube, and a strong thread is passed through the hole. The anesthesiologist then holds the tube in the usual manner and manipulates the thread with two fingers. In this way, the sharp upward curve at the end of the tube and the precise control of the tube, both so necessary to tracheal intubation, are obtained. Care must be taken that the thread does not injure tissues anterior to it. The thread can be knotted and left in place, or it can be withdrawn.

Double-Cuff Endotracheal Tube

It is no exaggeration to say that the patient's safety and perhaps his life may depend on airtight endotracheal anesthetization connections at any time during surgery, particularly in thoracotomy and in operation for intestinal obstruction. It is sometimes a harrowing experience for the anesthesiologist to discover a serious leak in the inflatable cuff while surgery is going on, particularly when thoracotomy is being performed.

With the conventional single-cuff tube, when a leak occurs, the anesthesiologist can resort to or is driven to any one of the following 10 remedial devices to (1) do nothing if the leak is small; (2) cut the balloon off; (3) keep adding air to the cuff; (4) intubate anew; (5) insert a pharyngeal pack; (6) change to nitrous oxide; (7) put a mask over the patient's face and the tube; (8) avoid pressure; (9) raise rates of flow; and (10) remove tube and convert to mask.

Where the endotracheal tube does not afford a leakproof system, anesthesia may become dangerously light, aspiration of gastric contents may occur, and pressure in the form of controlled or artificial respiration may be impossible. To overcome these difficulties, I have explored the possibility of attaching two inflatable cuffs to an endotracheal tube, so that a leak in the first cuff occurring during surgery can be remedied merely by inflating the second cuff. There is another advantage afforded by a double-cuff tube. Although keeping a cuff inflated too long may produce laryngeal ischemia or edema, the anesthesiologist may hesitate to deflate the cuff even for a little while during a long operative procedure; two cuffs can, of course, be alternately inflated and deflated, so that the pressure exerted by the cuffs occurs at different points in the trachea.



Endotracheal tubes. *A*, double-cuff tube. *B*, threaded tube.

In 150 consecutive intubations, leaks in the inflatable cuff system occurred 13 times, with 2 such leaks occurring in the balloon and thus easily reme-

---

Chairman, Department of Anesthesiology, Lincoln General Hospital, and Clinical Associate in Surgery, University of Nebraska College of Medicine.

died. Of the remaining 11 leaks, 5 were large and 6 were slight. Eleven leaks out of 150 intubations constitute an incidence of 7.3%. Assuming that a cuff will leak in 7% of all cases, then the numerical advantage of having a second cuff is easily calculated. The first cuff will leak in 7% of cases, but the second cuff will stop the leak 93% of the time, so that a two-cuff tube will leak in 7% times 7%, or in 0.5% of cases. A one-cuff tube will thus leak once in 14 times, while a two-cuff tube will leak only once in 200 times. It must be pointed out that all cuffs are tested on the tubes, under pressure, and under sterile water, before being used.

Since the balloon (hanging from the end of the catheter that leads to the inflatable cuff) serves little or no useful purpose and leaks all too frequently, it is my practice to cut it off and insert endotracheal tubes without balloons. It has proved possible to put two inflatable cuffs on an endotracheal tube; such tubes have been used successfully at the Lincoln Ge Hospital and are now employed routinely in ations in which leaks are disastrous, as in thoracot

There are five points of measurement to be loc on such a tube, and their distances from the d end of the tube are: (1) the proximal end of beveled opening, ⅝ in. or 15 mm.; (2) the beginnin the first cuff, ¾ in. or 19 mm.; (3) the joining of two cuffs, 2 9/16 in. or 65 mm.; (4) the end of second cuff, 4¼ in. or 108 mm.; and (5) the end of rubber or plastic endotracheal tube, 8¾ in. or 222

It is essential that the auxiliary or proximal exert most of its effect within 4 in. of the end o tube, since the trachea does not usually exceed in length. When the tube is finished, both bal are removed and the cuff-catheters are cut so they hang at uneven lengths; in this way, the thesiologist can always tell which cuff he is inf or deflating.

ELECTROMECHANICAL ARM SLINGS

Earl F. Hoerner, M.D., Beverly Konugres, O.T.R.
and
Donald Smith, B.S., West Orange, N. J.

Many disabled persons who have hands that are capable of functioning well are prevented from using them due to the loss of shoulder, arm, and forearm muscle power as a result of poliomyelitis or other causes. Electrically controlled slings can aid such severely disabled persons to adapt to their home and work environments. These electromechanical slings allow the person's arms to be placed in a wide variety of functional positions, from a 90-degree elbow flexion at a table level for the beginning phase of eating or working to a 90-degree shoulder flexion for such activities as reaching for food on the upper shelf of a cupboard or tools on a high ledge (fig. 1).

The slings can be lowered to a level where the person can independently "crawl" or be placed into the elbow and forearm slings; then, by the use of a switch, the arms are brought to the level at which the patient desires to function or work. The maximum pressure needed to raise the hand to the mouth by use of these slings is less than ¼ lb. on the electrical switch. This pressure can be applied by flexion of the finger tip, toe movement, shoulder shrug, leg movement, or even flexion and extension of the neck.

When both the upper arm and the forearm are su ported, a broader variety of hand activities can performed with greater coordination and less physi fatigue. Activities of daily living such as eating, sh ing, brushing teeth, or combing hair can be acco plished efficiently by first electrically lowering arms to the selected level for picking up the necess implement and then pressing the switch to raise arm to head level.

Since the range of shoulder motion, with th slings, can vary from a 0-degree extension to 90-deg forward flexion, occupational activities requir bilateral arm movements, such as soldering, electri wiring, mechanical drawing, and woodworking, be performed (fig. 1). As each sling is separately c trolled and operated, the arms can be placed in needed position of function as indicated by the oc pational pursuit.

The apparatus is composite and can be convenie connected to a standard wheel chair or table. No ad tional apparatus is necessary. This standardizat makes its use practical for different persons with va ing degrees of muscle-power involvement. The elec mechanical sling (1) aids the severely handicap person in his performance of the activities of d

---

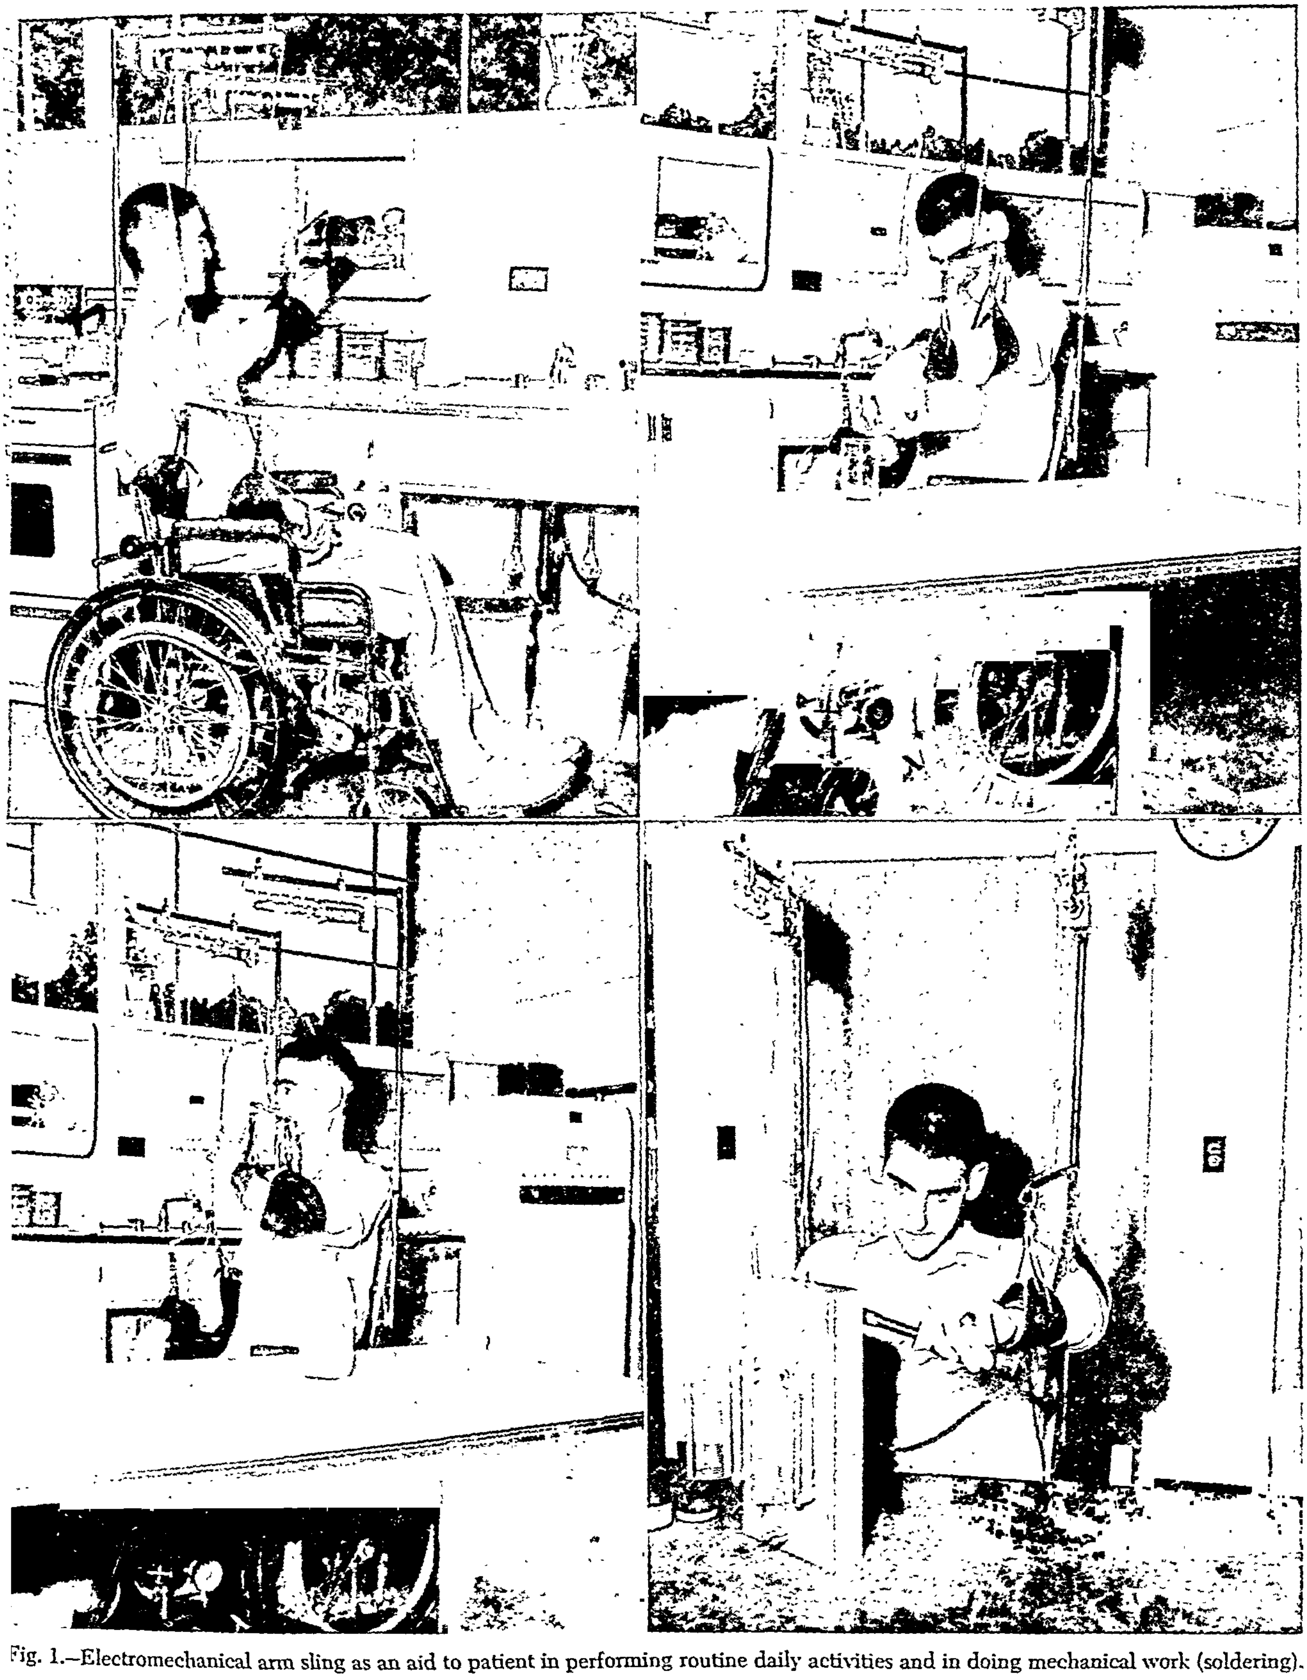

Fig. 1.–Electromechanical arm sling as an aid to patient in performing routine daily activities and in doing mechanical work (soldering).

living; (2) increases the scope of occupational opportunities; (3) supports the shoulder, arm, and forearm; and (4) permits greater range of motion for activities that require bilateral action.

Construction

The principle of operation of the electromechanical overhead *arm sling lies in the fact that a cable,* which suspends the arm sling, winds and unwinds around a spindle attached to an overhead bar. This motion of the sling results in elevation and lowering of the arm (fig. 2). The basic structure is a modification of the standard right-angle overhead bar that is affixed to the upright part of the back of a standard wheel chair or a table. The perpendicular section of the bar is placed so as to rotate freely in a 360-degree arc, thus making the horizontal overhead section available for wide lateral *arm motion* when the patient is in t sling. *Holes* are *drilled* in the overhead horizontal b at *the proper places* for holding of the spindle, mo and relay unit.

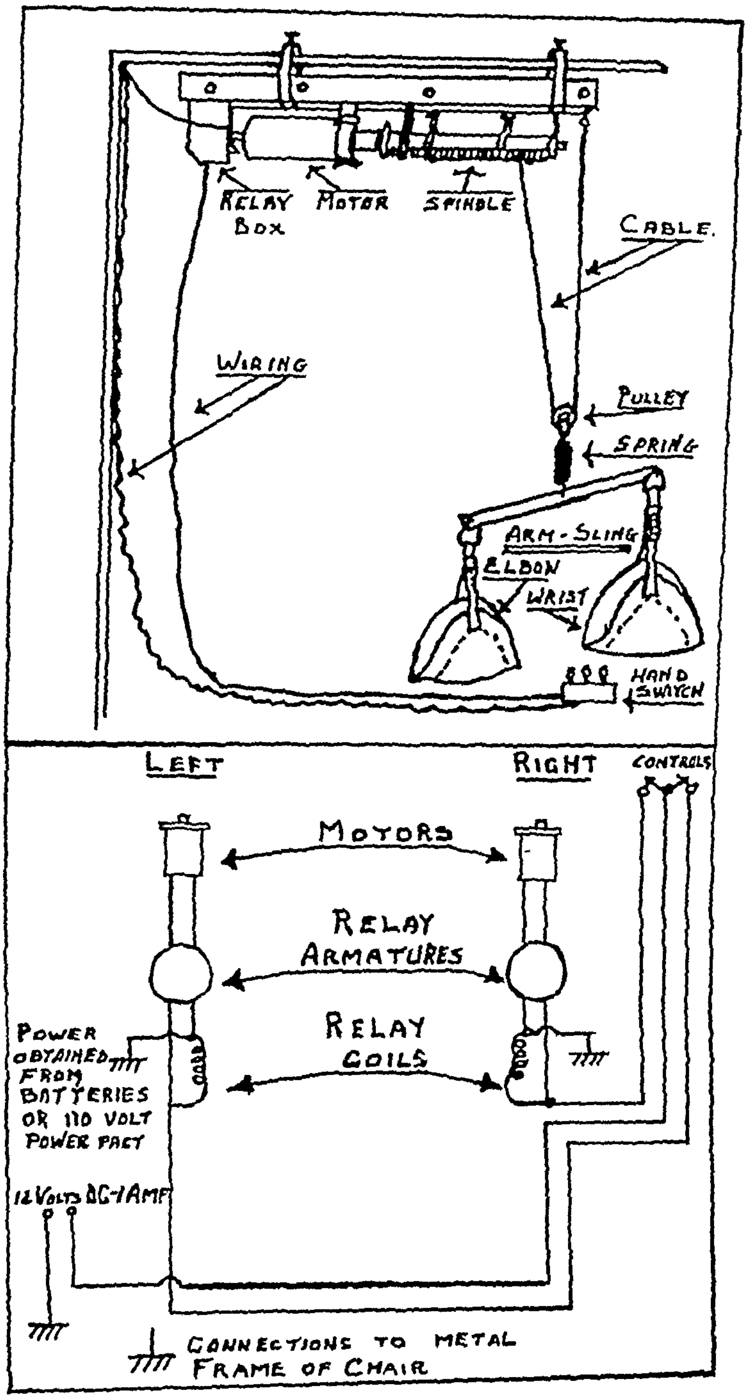

Fig. 2.—Diagram showing principal parts of, and wiring system for, arm-sling unit.

The spindle is a metal cylinder that is grooved, o lathe, like a *screw, so* that the cable which suspe the *sling may* wind and unwind without snagging o bunching. The spindle is set into ball bearings at ea end to reduce friction and is attached at one end to cylindrical 12-volt D. C. *motor* (240 *rpm*) with a bu in gear. The motor, in turn, is connected to a re unit of the type used in toy train locomotives. T switch is controlled by a hand, a foot, the neck, o other part of the body. The relay unit controls t direction of the motor and, hence, the spindle in clockwise or counterclockwise direction.

The cable which suspends the sling is fixed at o end to the overhead bar and at the other end to t spindle; it first passes through a pulley to which t *sling is fastened.* The electrical *unit is* so construct that, on the first closing of the switch, the sling elevate by means of the spindle's rotation in a cloc wise direction. *On the opening of the switch,* the slin stops at the desired height. The second closing of t switch *reverses the direction of the spindle* to counte clockwise *so that the sling may be lowered,* and o the opening *of the switch it stops in the desired* po tion. The whole unit is powered by a 12-volt batter that is located under *the seat of the wheel* chai Figure 2 *illustrates* the wiring *system* for a bilatera *electromechanical* arm *sling unit.*

Report of a Case

A 20-year-old male electrical-engineering student was ad mitted to a general hospital in September, 1954. The diagnosi was *poliomyelitis* with *paralysis of* all neuromuscular com *ponents of the trunk and extremities and respiratory* inadequacy The performance of a tracheotomy was *not necessary,* as ther was no bulbar involvement. Hospitalization in the gener hospital was *necessary for a period* of 18 months.

At the time of the patient's discharge from the general ho pital to his home and his entrance into a rehabilitation cente he presented the following status: A rocking bed was use during his sleep; a chest cuirass respirator was used for re periods of one-half to one hour twice during the day, and th patient could sit in his wheel chair without undue fatigue fo periods of from one to three hours without respiratory assist ance. Respiration was accomplished by use of the accessor muscles of the neck and by intercostal *movement.* The periph eral muscles showed considerable weakness, *and the* patient's lower extremities were completely paretic. There was no gros abdominal power. The head and neck were well controlled. There was marked lateral weakness in the shoulders and elbows, with lack of functional motion. Fair functional motion of the wrist, fingers, and thumb bilaterally was found. The patient was *unable to perform* any functional activities of any type.

After a thorough evaluation had been made and therapeutic procedures carried out, it was recommended that, due to the lack of return of further functional motion in any of the in- *volved systems,* mechanical devices be obtained and used by the patient. Electromechanical slings were obtained and fabricated by the patient *himself.*

Through training in the use of the electromechanical aid, the patient is *now available* for occupational placement. He has considered returning to school and, in conjunction with this plan, is now working with several *electronic* manufacturing companies as a consultant in the engineering and fabrication of similar devices *for* other disabled persons.

EFFECTIVE METHOD OF STRAPPING THE LUMBOSACRAL REGION

John T. Bate, M.D., Louisville, Ky.

fter the trial of several methods, over many years, treating the acute back pain which usually starts as atch or painful sensation when an individual who s bent over to pick something up (thus flexing the nbar spine and hips while the knees are straight) rts to resume the erect position, I have been able to ovide considerable immediate relief by a relatively expensive temporary support. This supports the nbosacral region in a relatively straight position, us embodying partially and temporarily the prinple of the Williams low-back brace.

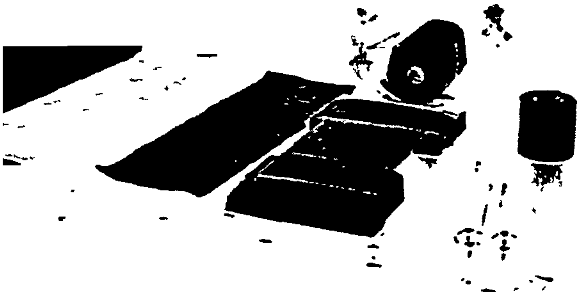

Fig. 1.—Showing the sponge rubber attached to the ends of e board, gauze to protect skin from rubber and board, 5 yd. 4-in. elastic bandage, and roll of 2-in. adhesive.

A wooden forearm splint of the type formerly wide- used in the treatment of fractures of the bones of ie forearm, made of a firm, soft type of wood (not icca or basswood), 18 in. long, 4 in. wide, and $\frac{3}{16}$ in. iick, is sawed into two equal lengths. To each end f one half of this board is attached a piece of sponge ibber. While many thicknesses and dimensions could e used, a satisfactory size is 5 in. by 4 in. by ½ in. This placed so as to overlap the end of the board, about in., and the sides ½ in., and held in this position with small piece of adhesive tape. Two strips of folded auze cut from a package of sterile gauze, each about 2 in. long, 4 in. wide, and consisting of four folded iicknesses are placed over the sponge rubber and oard in such a way as to prevent either from coming contact with the skin (fig. 1). The skin of the lumar region of the back flanks and the sides of the abomen are painted with compound tincture of benzoin. sufficiently large place of the gauze of the kind hich was used to cover the splint is now cut and pened up so as to cover the anterior surface of the bdomen and prevent the elastic adhesive from stickg to the hair. With the padded splint placed so that ne portion of the sponge rubber fits over the proximal portion of the sacrum and the other over the upper lumbar, or lower dorsal region (fig. 2), it is now held in place by means of 5 yd. of 4-in. elastic adhesive bandage applied circularly. The end of the elastic adhesive is fastened in place with the usual type of 2-in. adhesive and the protruding gauze is turned down so as to protect the protruding end of the sponge rubber and is held in place with adhesive.

Depending upon the type of skin the individual has, this can be left in place for three to six days. When combined with medication and the usual instructions as to posture, bed, and methods of protecting the lumbar region, this method of strapping will often relieve the simpler forms of back pain within this period. Occasionally, reapplication may be decided on in an individual who has obtained much relief, is satisfied, but thinks he needs the support for a few days longer.

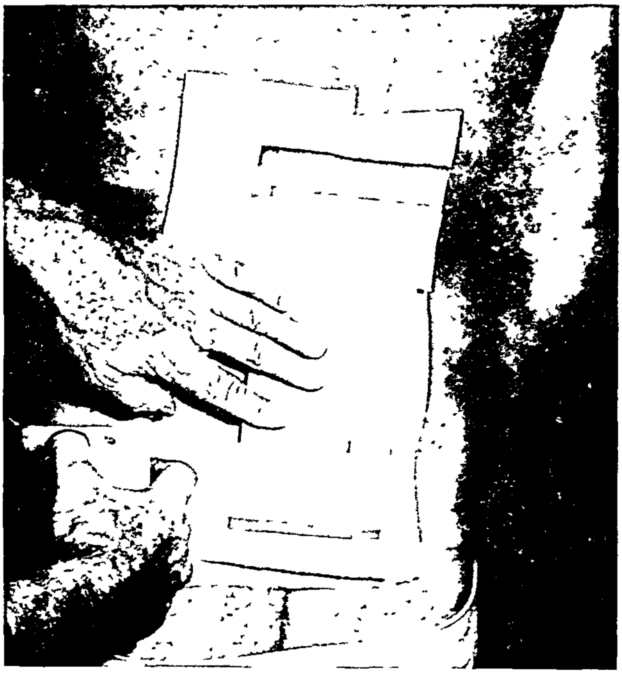

Fig. 2.—The padded board being applied. The upper part was brought into midline before the circular strapping was completed.

This method gives the best results in individuals who have definite acute muscle spasm of a few hours' to a few days' duration. More severe and chronic cases, of course, require other, or additional, treatment.

301 W. Ormsby.

ACUTE TRANSIENT MYOPIA ASSOCIATED WITH USE OF ACETAZOLAMIDE (DIAMOX)

Samuel S. Binder, M.D.
and
Willard Steele Sr., M.D., Chattanooga, Tenn.

Acetazolamide (Diamox) has become a popular drug in the practice of obstetrics and gynecology. Its value in the treatment of premenstrual tension has been described by Greenblatt.[1] Assali and co-workers[2] have also mentioned its action in treating edema of pregnancy. In other branches of medicine, acetazolamide has been used for the treatment of congestive heart failure,[3] glaucoma,[4] and epilepsy.[5]

The toxicity and side-reactions described have been minimal and in our experience have consisted mainly of tingling sensations in the fingers and occasional drowsiness. We have observed an unusual side-reaction that was quite alarming to the patient and somewhat baffling to the physicians. This consisted of an acute transitory myopia. One other such case has been reported by Black.[6]

Report of a Case

The patient was a 30-year-old woman, seen for the first time on Aug. 21, 1956, with the complaints of severe abdominal swelling, lower abdominal pain, and marked irritability. These symptoms were noted approximately one week premenstrually and had been present for the past 10 months. The menstrual periods were regular but scant and associated with severe dysmenorrhea. Her latest period had begun on Aug. 15 and had continued for four days. She was gravida 2 para 2, her last pregnancy having occurred five years previously. Six months after this pregnancy she had had a dilatation and curettage and cervical conization performed but no other surgery. The remainder of her history was negative.

Physical examination showed a blood pressure of 110/80 mm. Hg, pulse rate 76, and weight 143.5 lb. (65.1 kg.). General physical findings were within normal limits. There were no abdominal masses, and pelvic examination revealed no gross abnormalities. The hemoglobin level was 12.6 Gm. per 100 cc., and urinalysis was negative. It was felt that the patient had a symptom complex consistent with premenstrual tension. As part of her therapy, she was advised to be on a low-salt diet and was given acetazolamide intermittently for 10 days premenstrually. The dosage was 250 mg. daily, for four days; this was stopped for two days and repeated for four more.

On Sept. 2, the patient was in an automobile accident and received a bump on the head. At the scene of the accident, she was checked by a physician who reported no evidence of injury. Acetazolamide therapy was started on Sept. 4 and continued for four days, stopped for two days, and continued for two more days. On Sept. 9, the patient's vision became blurred, and the next day she was seen by one of us (W. S.) for ophthalmological examination. Her vision on Sept. 10 in each eye was 20/100, improved to 20/20 with a −2 sphere lens in each eye. The ocular tension was normal, there was no muscular imbalance, the fundus showed no changes, and pupillary reactions were normal.

The patient was advised to discontinue all medication. She returned to the office of her gynecologist (S. S. B.) on Sept. 12. Her vision was considered worse, and no improvement noted in her premenstrual tension. She was emotionally u and feared that she was going blind. On the same day, returned to her ophthalmologist, who found that she had come more myopic. Her vision was 20/300, corrected wi −4.5 sphere to 20/30 in each eye. Ocular tension was nor and no opacities were noted. Visual fields were normal. underlying cause of her condition was not apparent.

A glucose-tolerance test, performed on Sept. 13, reveale normal curve. A repeat ophthalmological study on Sept. and Sept. 24, after the completion of her menstrual pe revealed a complete remission of symptoms, and her eyes was 20/20 bilaterally on both days. Subsequent follow-u this patient revealed a cervical stenosis which was relieve cervical dilation. After this procedure, her dysmenorrhea improved. The premenstrual tension was relieved by other medication along with a low-salt diet.

Comment

Acute refractory changes have been noted in m bolic disorders such as diabetes mellitus. Emacia diseases, causing dehydration and acid-base im ances, have also caused refractory errors. The al tion of vision may stem from changes involvin areas of the visual apparatus. Transient myopia been reported with the use of arsenicals, disulf and sulfonamides.[7] Irritative spasm of the ci muscle, osmotic changes in the lens, and local encephalitis (possibly due to allergic sensitivity) been some of the explanations offered by Duke-El The same author concludes that "the mechanis the refractive changes, however, is by no means c Acetazolamide is a sulfonamide,[9] and it is quite sible that the reaction described in the case of patient is on the same basis as those previously cussed.

Suite 201, Doctors Building. (4) (Dr. Binder).

COUNCIL ON DRUGS

NOTICE OF CHANGE IN OPERATION

LISTING OF PREPARATIONS WITH MONOGRAPHS

As an aid to physicians in writing prescriptions, the Council has adopted an expansion of the section in New and Nonofficial Drugs, "Principles Governing the Evaluation of Drugs Described in New and Nonofficial Drugs," to provide for listing pharmaceutical preparations, including either sizes or strengths, in conjunction with monographs published in the Council's column of The Journal and in future annual editions of New and Nonofficial Drugs. Available dosage forms, and either sizes or strengths, will be listed alphabetically according to appropriate nonproprietary pharmaceutical terminology only. In order to avoid undue expansion of monographs, with this kind of information, available sizes or strengths will be limited to dosage units or concentrations, depending on the type of formulation.

The listing of available preparations, which is instituted with this issue of The Journal, should not be construed as affecting any statements in monographs that may be critical of the usefulness, safety, suggested dosage, concentration, or particular route of administration of a drug. However, it is hoped that this added feature will increase the usefulness of the Council's publication to physicians when such information is desired for prescribing.

The Council will continue to list applicable commercial names of evaluated drugs of which it is informed and urges the continued cooperation of industry in supplying scientific data and reports of investigations to aid in the early evaluation of new drugs. Commercial outlets are further invited to supplement such future data with information on available dosage forms, sizes, and strengths or otherwise to inform the Council respecting any additions or corrections concerning preparations which are included in subsequently published monographs. The Council also desires information concerning adverse reactions to drugs that may appear after extensive use.

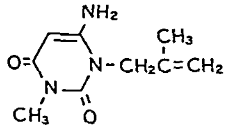
This notice of the desire of the Council to include dosage preparations and to continue its policy for listing commercial names will not be repeated in the Council's column of The Journal, since statements to this effect will appear annually in New and Nonofficial Drugs.

NEW AND NONOFFICIAL DRUGS

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Drugs are based on the evaluation of available scientific data and reports of investigations.

H. D. Kautz, M.D., *Secretary.*

Amisometradine.—1-Methallyl-3-methyl-6-aminotetrahydropyrimidinedione.—The structural formula of amisometradine may be represented as follows:



Actions and Uses.—Amisometradine, an orally effective, nonmercurial diuretic agent, is a structural isomer of aminometradine, and its pharmacological actions are similar to those of the latter agent. Thus, amisometradine is proposed for the maintenance of an edema-free state in patients responsive to diuretic therapy and for the initiation of diuresis in most edematous conditions except severe congestive heart failure. The drug also may reduce or, in mild cases, eliminate the need for parenteral injections of mercurial diuretics. Amisometradine has been successfully employed for the gradual mobilization of edema fluid in a substantial number of patients with mild to moderate congestive heart failure, hepatic cirrhosis, and the nephrotic syndrome. It has also been useful for the management of water and electrolyte retention during pregnancy (mild preeclampsia) and in the premenstrual period.

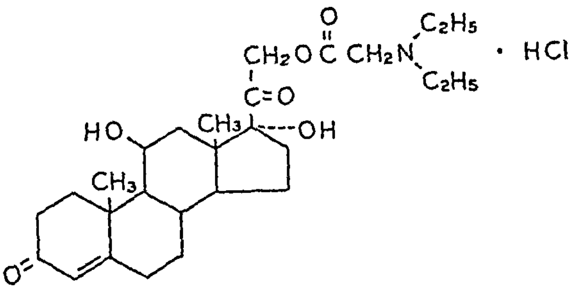
The chief difference between amisometradine and aminometradine lies in the possibly diminished incidence of gastrointestinal upsets associated with the former drug. Some data have indicated that whereas nausea or vomiting occur in approximately 20 to 30% of patients to whom aminometradine is administered, this incidence is reduced to about half, or 10 to 15%, when amisometradine is employed. Thus, from the standpoint of patient tolerance, amisometradine appears to offer some advantage. Since the clinical effectiveness of both drugs appears to be about the same, it seems likely that amisometradine may eventually replace aminometradine for the treatment of edema.

Amisometradine has not been extensively studied from the standpoint of serious toxic effects, and although the drug so far has not been observed to cause such reactions, physicians should be alert to the possibility of their occurrence with extensive and prolonged use.

Dosage.—Amisometradine is administered orally. Dosage is governed largely by severity of edema and individual response as reflected by the serial weight record of the patient. As a general guide, 400 mg. may be administered four times daily with meals on the first day of therapy and twice daily thereafter. Patients with mild edema may be satisfactorily maintained on 400 mg. or less per day. On the other hand, daily amounts up to 3.2 Gm. may be required in more severe cases.

Preparations: tablets 400 mg.
Applicable commercial name: Rolicton.
G. D. Searle & Co. cooperated by furnishing scientific data to aid in the evalution of amisometradine.

Hydrocortamate Hydrochloride.—17-Hydroxycorticosterone-21-diethylaminoacetate hydrochloride.—The uctural formula of hydrocortamate hydrochloride may be represented as follows:

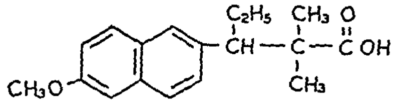


Actions and Uses.—Hydrocortamate hydrochloride, an ester-salt of hydrocortisone, is used for the treatment of dermatoses known to be responsive to topical gluco-corticoid therapy. The drug exerts an excellent anti-inflammatory action against such cutaneous eruptions and is believed to be approximately twice as potent, milligram for milligram, as free hydrocortisone or its acetate ester. Thus, hydrocortamate hydrochloride is effective against acute or chronic dermatoses that have an allergic or inflammatory basis and are associated with pruritus. These would include, among others, such conditions as atopic and contact dermatitis, pruritus with lichenification, seborrheic dermatitis, and nonspecific anogenital pruritus. Clinical experience to date has been confined largely to short-term therapy on relatively limited areas of the body. Although the possibility of systemic reaction after prolonged or intensive therapy does exist, this appears to be quite unlikely. To date, no reactions suggestive of systemic absorption have been observed with hydrocortamate hydrochloride or with any other topical preparation of hydrocortisone. Likewise, no appreciable changes in eosinophil counts or excretion of 17-ketosteroids have been demonstrated after such therapy. Nevertheless, pending the accumulation of more information on this subject, hydrocortamate hydrochloride should be used cautiously in long-term therapy, especially in cases in which large areas of abnormal skin surfaces are involved. The drug should not be applied to infected areas. Its sensitizing potential is not known, but in view of its similarity to other local preparations of this class, this is considered to be negligible. The ointment base rather than the drug may elicit some sensitization in particular instances.

Dosage.—Hydrocortamate hydrochloride is applied topically in a 0.5% ointment (5 mg. per gram). A small quantity should be applied to the affected areas of skin two or three times daily.

Preparations: ointment 0.5%.
Applicable commercial name: Magnacort.
Pfizer Laboratories, Division of Chas. Pfizer & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of hydrocortamate hydrochloride.

Methallenestril.—α,α-Dimethyl-β-ethyl-6-methoxy-2-naphthalenepropionic acid.—3-(6-Methoxy-2-naphthyl)-2,2-dimethylpentanoic acid.—The structural formula of methallenestril may be represented as follows:



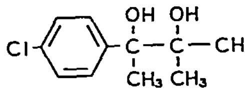
Actions and Uses.—Methallenestril, a nonsteroid estrogenic compound, is effective orally, and its onset of action is prompt. Its estrogenic potency, milligram for milligram, is apparently no greater than that of orally administered estrone; it is only about one-tenth as potent as diethylstilbestrol. Methallenestril causes less gastrointestinal upsets than does diethylstilbestrol. Otherwise, its administration in therapeutically effective doses is followed by about the same degree of nausea as is found with the other synthetic estrogens. In the reports available to date, there is some indication that methallenestril therapy may cause less withdrawal bleeding than do the other estrogens. However, if dosage is adjusted sufficiently to produce a comparable therapeutic effect, endometrial proliferation and subsequent withdrawal bleeding may be expected. Methallenestril is useful for the same conditions for which other natural and synthetic estrogens are employed and is subject to the same contraindications. (See the general statement on estrogens in New and Nonofficial Remedies.)

Dosage.—Methallenestril is administered orally. The usual initial dosage for menopausal symptoms is 6 mg. daily for three weeks; thereafter dosage is decreased

3 mg. daily for as long as required. For suppression lactation, 20 mg. is administered daily for the first e postpartum days. Doses of 6 mg. daily for four eks may be given for the treatment of postmeno-usal vaginitis, kraurosis vulvae, and pruritus vulvae. the initial treatment of postmenopausal osteoporosis, mg. per day for two weeks is usual; maintenance sage is 3 mg. daily. For the palliation of prostatic rcinoma, daily doses of 20 mg. may be administered.

Preparations: tablets 3 mg. and 20 mg.
Applicable commercial name: Vallestril.
G. D. Searle & Co. cooperated by furnishing scientific data aid in the evaluation of methallenestril.

Phenaglycodol.—2-*p*-Chlorophenyl-3-methyl-2,3-bu-nediol.—The structural formula of phenaglycodol ay be represented as follows:



Actions and Uses.—Phenaglycodol is one of a series f synthetic diol compounds that exert a mild depres-ant effect on the central nervous system. At least at he level of the spinal cord, the drug has properties n common with the interneuronal blocking agents such as mephenesin and meprobamate. Phenaglycodol and meprobamate have a common chemical derivation rom mephenesin. In the case of phenaglycodol, a degree of metabolic stabilization is achieved by full substitution on the OH-bearing carbon atoms. In experimental animals, phenaglycodol produces some degree of skeletal muscle relaxation and exerts an inhibitory influence on transmission through polysynaptic pathways. It also diminishes the severity of electrically induced convulsions in animals, and initial clinical experience has suggested a possible usefulness in epilepsy. As a muscle relaxant, phenaglycodol is much less potent than mephenesin. From the standpoint of overall clinical usefulness, phenaglycodol is probably most closely comparable to meprobamate. Hence, it may be characterized as a mild sedative with weak muscle-relaxing properties.

Phenaglycodol has been used to produce a calming or mood-ameliorating effect in patients with emotional instability, anxiety-tension states, and functional disorders. Although early reports have been favorable, there is need for more evidence to establish conclusively its usefulness as a psychotherapeutic agent. Studies designed to compare its tension-relieving effects with meprobamate are inconclusive. In some patients with anxiety states, the drug has elicited a degree of behavioral improvement; in other studies the effect has been primarily that of a placebo. In general, phenaglycodol appears to be similar in effectiveness to meprobamate, but the ultimate usefulness of this type of drug must await the results of further clinical experience.

From the evidence available to date, it would appear that phenaglycodol may have usefulness in the adjunctive management of simple neuroses. The drug probably has no place in the treatment of the more severe psychotic type of mental disturbance and cannot be classified as a tranquilizing agent in the same sense as chlorpromazine or reserpine.

The toxicity of phenaglycodol is low. No adverse effects on hepatic or hematopoietic function have been observed after long-term administration to animals and patients. In clinical experience, large doses are apparently without effect on blood pressure, pulse, or respiration. To date, drowsiness appears to be the only side-effect referable to therapy with phenaglycodol. This has occurred only occasionally and generally follows the administration of high doses.

Dosage.—Phenaglycodol is administered orally. The usual dosage for adults is 300 mg. three or four times daily.

Preparations: tablets 300 mg.
Applicable commercial name: Ultran.
Eli Lilly and Company cooperated by furnishing scientific data to aid in the evaluation of phenaglycodol.

Use of Ethchlorvynol for Daytime Sedation

The Council has evaluated the use of ethchlorvynol (Placidyl) for daytime sedation. This nonbarbiturate hypnotic has previously been described as useful for the induction of sleep in selected patients with simple insomnia. (See the monograph on ethchlorvynol in New and Nonofficial Remedies.) On the basis of additional evidence, the Council concluded that the drug may also be given in small doses during the day to allay or calm certain patients with organic or functional disorders characterized by anxiety or tension. Its clinical employment for this purpose has been confined largely to patients with mild anxiety neuroses, hypertension, and various skin diseases. It has also been used on a limited scale in patients with asthma, peptic ulcer, and cardiac disorders. Currently available evidence indicates that the drug exerts a mild sedative effect in such patients and that the incidence of side-effects is low (about 8%). Side-effects so far encountered include drowsiness, fatigue, hang-over, ataxia, vertigo, headache, nightmares, mental confusion, bad after-taste, nausea, and vomiting. There has been no observed tendency toward development of psychic dependence or habituation. Pending the accumulation of more clinical information, however, this possibility should be kept in mind, particularly when the drug is used over prolonged periods of time.

Dosage of ethchlorvynol for use as a daytime sedative should be individualized according to the response of the particular patient. Oral dosage usually ranges from 100 mg. twice daily to 200 mg. three times a day. If the drug appears to be rapidly absorbed, producing transient giddiness or ataxia, these side-effects will be minimized if the medication is given with a glass of milk or other light refreshment.

The Council voted to expand the monograph in New and Nonofficial Drugs to describe the use of ethchlorvynol as a daytime sedative.

Abbott Laboratories cooperated by furnishing scientific data to aid in the evaluation of this additional use of ethchlorvynol.

MAN CONTRACTING RABIES FROM MAN

GUEST EDITORIAL

Karl F. Meyer, M.D.

THERE has been much recent publicity concerning the administration of the Pasteur antirabies treatment to persons who were in contact with a patient who died of rabies. The indications for giving vaccine for rabies prophylaxis should be clearly understood. The following case illustrates the principles involved.

In July, 1956, a man was bitten by his dog while attempting to train her. The dog had no illness at that time but ran away and never was located. In April, 1957, the patient complained of headache followed by nausea and vomiting. Four days later he became severely ill, was unable to swallow, and was extremely apprehensive. That evening he was admitted to the hospital, where in addition to his extreme agitation he suffered from thirst and fear of water. He was removed to a mental hospital, where rabies was diagnosed. He died that evening, five days after the onset of his illness. Postmortem examinations and laboratory studies revealed Negri bodies in the brains of mice inoculated with tissue from the patient's brain. During the course of his illness the patient vomited and expectorated large amounts of saliva which contaminated the skin and clothing of most of the persons who tried to treat or restrain him.

The diagnosis of furious human rabies in a person who had thus contaminated his environment makes it necessary to decide whether the persons exposed to the patient should receive antirabies vaccine. This is always a difficult decision. A wave of anxiety, nearing hysteria, must be anticipated. People who have been with the patient during and before his illness will demand antirabies treatment. Babes in 1912 stated that human rabies presents little danger, because he knew of no case of transmission from man to man. That rabid human beings may bite others was well documented by observations at the Vienna Pasteur Institute in 1926.

In a critical review of older studies, Joseph Koch in 1930 emphasized that human-to-human transfer of rabies through bite or other means was rare and that a conclusively proved transmission had never been reported. The most comprehensive recent summary on rabies[1] mentions that the mother of Malpighi in the 17th century died from rabies after a bite inflicted by her daughter. Without documentation he stated that human rabies had followed the bite of rabid persons in Russia. During my recent visit to Russia I heard reports that rabies was transmitted from man to man by homeless orphans who roamed the streets of Moscow during the period after the revolution when medical and public health services were almost nonexistent. Few of these transmissions have been epidemiologically or etiologically investigated. In 1898 Palmirski and Karlowski in reporting the case of a man who became infected through coitus concluded that this was the only proved instance of interhuman transmission of rabies. Authorities believe, however, that transmission in this case was probably through the saliva.

Every thoughtful report on this subject advises that precautions be taken by attendants to avoid contact with saliva of rabies-infected patients. There is ample documentary evdience that rabies virus may be present in the saliva of human beings with rabies. As early as 1823 Magendie and Berschet infected a dog with human saliva. In 1881, Pasteur and his associates and Raynaud and his associates transmitted rabies to rabbits with saliva from rabid patients. Bardach in 1888 demonstrated salivary gland infections in human beings. Pertarelli in 1905, Keirle in 1898, Nicolle and Chaltiel in 1907, and Cruickshank and Wright in 1914, using rabbits as indicator animals, succeeded in producing rabies with saliva from rabid persons. In the United States, Sulkin and Harford in 1934 tested the saliva in two fatal human rabies infections and succeeded in isolating the virus in one. At the Pasteur Institute in Odessa, Palawandow and Serebrennaja in 1931 by intramuscular injection of guinea pigs demonstrated the rabies virus in the saliva of four of five patients studied. The saliva of six persons with paralytic rabies in Trinidad proved positive for rabies when injected into rabbits by Pawan in 1937.

The fact that rabies virus is transmissible through the saliva from human beings infected with rabies to various species of animals has been proved in many observations recorded in the past 30 years.

2. Wright, G. P.: Neurotoxins of Clostridium Botulinum and Clostridium Tetani, Pharmacol. Rev. 7:413-465, 1955.

The infectivity of the saliva has never been measured. It is probably slight but of adequate virulence to incite disease if properly introduced into scratch or bite wounds. These observations, together with those of Manouelian in 1936, who found Negri bodies in the endoneurocytes of the sensory and sympathetic fibers of the face and in the sympathetic ganglions and virus in the salivary and lacrimal glands in patients with rabies, suggest that the virus diffuses through the peripheral nervous system in man as in animals. Despite the observations and the extensive experimental work, the pathogenesis of rabies is in need of review. In particular, the role of blood and lymph requires investigation. There are evident similarities to the much-debated question of the spread of neurotoxin of Clostridium tetani and Cl. botulinum.[2]

The above-described patient dispersed saliva indiscriminately by spitting frequently at random and directly into the eye of a nurse. The secretion soiled the hands of a nurses' aide who had a weeping eczema. Another nurse was bitten by the patient while she was attempting to hold a mouth gag between his teeth. The patient's son, who was with his father throughout the illness, was scratched rather badly and had contact with saliva. Knowing that the saliva may contain rabies virus in human infections, one is duty-bound to treat instances of bite and exposure to saliva. The maniacal behavior of the patient was largely responsible for the fact that every person who tried to restrain him became soiled with saliva. The practical question is not whether prophylactic rabies treatment should be instituted but how to keep its use to an irreducible minimum. Probably twice as many contacts as really need it receive the Pasteur treatment. Any physician with the imprint of maniacal human rabies fresh in his mind will fully understand this situation. This is in the best tradition of preventive medicine.

The main reason why conclusive evidence of human-to-human transmission of rabies has not often been published is doubtless that all persons in intimate contact with the saliva of a rabid person are treated the minute the diagnosis is proved by laboratory tests.

THE ORAL CAVITY AND DISEASE

Sir William Osler has called the oral cavity a mirror of the rest of the body. Yet while the changes in eyegrounds that are associated with systemic diseases are well recognized, the changes in and around the mouth do not seem to have equal appreciation by the physician.[1]

Oral tissues are unusually sensitive indicators of the general health status of an individual. This easily accessible, painless diagnostic site particularly reflects initial signs of nutritional deficiencies, endocrine imbalances, gastrointestinal disturbances, communicable diseases, blood dyscrasias including the anemias, and excessive exposure to radioactivity. In addition to the many peridontal manifestations of medical illness, not the least important reflection of disease can be demonstrated by the teeth themselves. Up to 37% of persons with congenital syphilis have been found to have hypoplasia of the occlusal surface of all four first molars.[2]

With growing emphasis on the dangers of an individual receiving too much radioactivity, it is important to know what specific changes the oral cavity does show as a result of exposure to radiation. Along with the commonly recognized signs of overexposure to naturally occurring or man-made radioactive substances, such as alopecia, brittleness of the nails, and pigmentation,[3] certain diagnostic signs appear in the mouth. In a population exposed to atomic bombing, petechial mucosal lesions have been observed associated with aplastic anemia. Other signs include a glassy smooth tongue that is particularly susceptible to infection, gangrenous ulcers of the lips, and ulcers that penetrate large areas of the buccal mucosa. It is believed that the mucosal findings are similar to those occurring elsewhere throughout the gastrointestinal tract.[4] Exfoliation of the teeth due to osteomyelitis of the mandible was frequently observed. One interesting finding was the increased radiant energy detected in the metallic restorations of the mouth that was not present in the adjacent living tissue.

Dental x-ray pictures can reveal the only signs of osteonecrosis and osteomyelitis that might occur from overexposure in x-ray technicians, as well as research men and others closely associated with radioactive substances. Finally, one of the most commonly reported signs of overexposure to radiation is xerostomia, the dry mouth that results from lack of salivary flow. This manifestation does not depend solely on locally applied radiation but can reflect over-all body exposure.

While it may seem to some that the physician examining the teeth and surrounding structures is doing a dentist's job, or the dentist who diagnoses diabetes by oral lesions is overlapping into the medical field, oral manifestations of disease indicate the close proximity of the two doctors' areas of practice. The physician and the dentist working together have provided a much better understanding of oral medicine, and in mutually reciprocating their clinical findings, as well as their scientific research, they have markedly improved the overall care of the patient. The field of radiation protection may well be the impetus to enjoin in fact, not just in theory, the two health specialties.

ORGANIZATION SECTION

REPORT OF JOINT COMMISSION ON ACCREDITATION OF HOSPITALS

The August, 1957, bulletin of the Joint Commission on Accreditation of Hospitals (660 N. Rush St., Chicago; Kenneth B. Babcock, M.D., director) is reproduced here for the information it contains that will be of interest to many physicians.—Ed.

To provide quality care for patients in hospitals, scientific tools are a necessity for both diagnosis and treatment. Although the extent and complexity of these facilities depend upon the needs of the patients whom the hospital aims to serve, no hospital can be without basic laboratory and radiological services.

Clinical Laboratory

In every hospital there should be a well organized, adequately supervised clinical laboratory with the necessary space, facilities and equipment to perform those services commensurate with the hospital's needs for its patients.

Good personnel and supervision are very important factors. It would be ideal if every hospital had its own pathologist. This is impossible because the demand is greater than the supply. Also, the amount of work in smaller hospitals does not justify the full time services of a pathologist. The Joint Commission on Accreditation of Hospitals believes strongly that if a hospital does not have the full time services of a pathologist, it should at least have the services of a pathologist on a regular part time or consultative basis. A hospital is not criticised for sending tissues out to a pathologist but if that same hospital has not been visited by or had its laboratory supervised by a pathologist for quite a long period of time, it must of necessity be scrutinized very carefully as to quality of service given.

The employment of technicians registered by the American Society of Clinical Pathologists is a factor in evaluating quality of laboratory services. Here again the actual number employed means very little without taking into consideration the type of work performed. Very frankly, however, a hospital without the services of a pathologist and without registered technicians cannot objectively be regarded as giving quality care.

Besides supervision and competence of personnel, the hospital laboratory is evaluated on the basis of the adequacy, speed and completeness of its laboratory service. All reports should be signed and filed in the patient's record. Duplicate copies should be filed in the laboratory. A tissue file and index should be maintained in every hospital laboratory. This index should be according to pathological diagnosis. Whether this index be simple or comprehensive is a question of judgment of the hospital and its needs.

Oral requisitions for laboratory work are not condoned. Requisitions may be made out by the nurse, but there should be an original order for the procedure, signed by the physician. This order should either be on the patient's medical record or in the physician's order book.

In order for a hospital to be accredited, the Commission requires that a urinalysis and either a hemoglobin test or hematocrit determination be done on all patients admitted. These are minimal requirements and in many instances should be exceeded. Additional requirements should be recommended and approved by the medical staff. The Commission has no requirements concerning laboratory work on outpatients. These policies should be determined by the local medical staff.

In a modern hospital, it is desirable that the hospital have a blood bank, established and supervised under strict regulations. Where this is not possible, the hospital should have at least proper blood storage facilities under adequate control and supervision. For the patient's safety these storage facilities should have an adequate alarm system, notifying hospital personnel of loss of electric power or faulty temperatures.

The percentages of autopsies performed and their utilization as a teaching medium is a very important factor in the accreditation of a hospital, and of necessity is closely allied to the pathology department. The actual procurement of permission for autopsies is largely a function and responsibility of the medical staff. An autopsy should be performed by a pathologist, but where this is not possible, the next best person is a physician versed in autopsy procedure and protocol. Every good hospital should have its own morgue if physically possible. The number of hospitals without morgues is quite high and the number not doing autopsies is considerable. Autopsies, as a means of staff education and improvement of clinical knowledge, rank extremely high in the minds of the Commissioners of the Joint Commission. As a rule of thumb, the Commissioners believe that non-teaching hospitals should have at least a 20% autopsy rate and teaching hospitals at least a 25% rate. Many good physicians feel this rate is too low and every effort should be made to exceed it.

Attention has been called recently to the necessity for checking the calibration of special laboratory instruments and equipment regularly and periodically. Faulty thermometers and inaccurate colorimeters have been reported in several instances in hospitals. Further checking showed they had not been checked since placed in service.

Where possible, the hospital pathologist should be a member of the tissue committee, preferably in an ex-officio, consultative capacity. The question has been frequently asked, "Should the pathologist be a member of the medical staff, entitled to vote and hold office?" The answer to this question is not within the jurisdiction of the Joint Commission on Accreditation of Hospitals and is a matter of judgment for each individual hospital. It can be stated from observation and information from most hospitals, that the answer is preferably "yes" and is done in the majority of hospitals.

X-Ray Department

A hospital, to be accredited by the Joint Commission, must have diagnostic x-ray facilities available in the hospital building proper or in an adjacent clinic or medical facility which is readily accessible to the hospital patients, physicians and personnel. A hospital is not required to have therapeutic x-ray facilities.

In the x-ray department, the need for qualified personnel is greatly stressed. Every hospital should have a qualified radiologist, either full-time or part-time on a consultative basis, to both supervise the department and interpret films that require specialized knowledge for accurate reading. Hospitals without the services of a radiologist in any capacity, whose medical staffs read all films themselves, are not considered as rendering high quality care.

The presence of at least one technician registered by the American Registry of X-Ray Technicians is quite necessary in the opinion of the Commission.

The original signed report of an x-ray film interpretation should be filed in the patient's medical record. A duplicate should be filed in the department. An index of x-ray reports according to radiological diagnosis should be kept.

The department should be free from all fire and explosion hazards and the equipment shock-proof. All proper and usual safety measures should be present. Personnel should be checked periodically (two times yearly at least) by blood counts and exposure tests.

Because of the special hazards encountered in the usage of fluoroscopes, radium and isotopes, recommendations emanating from the American Medical Association, the American College of Radiology, the American Hospital Association, and approved by the Commissioners of the Joint Commission on Accreditation of Hospitals, have been synopsized and are reproduced below for guidance and information purposes.

I. a. The use of fluoroscopes and radiographs in the department of radiology in institutions should be limited to members of the staff—either medical or lay—who have been designated as qualified by the radiologist or roentgenologist, and the use of fluoroscopes and radiographs in departments or divisions other than the department of radiology should be limited to members of the staff—either medical or lay—who have been designated as qualified by the radiologist or roentgenologist or appropriately constituted committee.

b. A special sheet should be included in all hospital and clinic charts for data of fluoroscopic examinations specifying date, site, roentgens per minute, exposure time, and operator.

c. All institutions should be requested to use timers on all fluoroscopes.

II. a. The use of radium element, its disintegration products, as well as radioactive isotopes, *shall be under the supervision of a physician* with certification, or its equivalent, in radiology or therapeutic radiology.

b. No one shall be permitted to use radium element, its disintegration products, as well as radioactive isotopes, unless he has been designated as qualified by the radiologist or an appropriately constituted committee.

c. Regulations shall be established, on the recommendation of the medical staff, as to the administration of the application and removal of these materials.

d. Ideally, a department having a supply of radium element, its disintegration products, as well as radioactive isotopes, should have a physicist qualified in radiation physics by the Board of Radiology, preferably as a full-time member of the department; such a physicist to be available in consultation for dosage problems involving radium as well as responsible for the safe housing of radioactive isotopes, the protection of patient and personnel, and the disposal of waste products.

Accreditation of Psychiatric Hospitals

A joint statement was sent by the American Psychiatric Association and the Joint Commission to every mental institution in the United States and Canada announcing that after Jan. 1, 1958, the Joint Commission would survey mental institutions on request. Mental institutions already on the accredited list published by the Joint Commission will automatically be surveyed at the proper time and they will be notified at least two weeks in advance.

Mental institutions never previously surveyed should notify the Joint Commission of their desire for survey. Schedules of surveys are made up months in advance and any request should be in the hands of the Commission before Jan. 1, 1958, to insure survey if possible for the forthcoming year.

Please note the Joint Commission's survey does not eliminate survey by the American Psychiatric Association if so desired and requested.

Publication

Every hospital accredited by the Joint Commission on Accreditation of Hospitals for three years (full accreditation) has been sent a copy of the new pamphlet entitled, "You Can Have Confidence in Your Hospital."

In the future, all hospitals that have been nonaccredited or accredited for one year will be sent a copy when accreditation for three years has been attained.

This pamphlet was prepared for hospitals to use as a device to explain to patients and the community what accreditation means. It is already proving quite successful.

FEDERAL MEDICAL LEGISLATION

First Session, 85th Congress

Tax Deduction for Higher Education

Senator Langer (R., N. D.) proposes, in S. 2479, to amend the Internal Revenue Code, allowing a taxpayer, in calculating his income tax, to deduct from his adjusted gross income amounts paid by the taxpayer during the taxable year for tuition fees, books, and supplies, for himself, his spouse, or a dependent attending college. This bill was referred to the Finance Committee.

Cigarette Labeling

Senator Bennett (R., Utah), in S. 2554, would amend the Food, Drug, and Cosmetic Act by requiring that any package or carton of cigarettes introduced in interstate commerce bear a label containing the following words: "WARNING: Prolonged use of this product may result in cancer in lung, heart, and circulatory ailments, and in other diseases."

Representative Fino (R., N. Y.), in H. R. 8947, proposes to provide "that cigarettes sold in interstate commerce shall be packaged and marked so as to show the nicotine content and the tar content of the cigarettes in each package." Both measures were referred to the Interstate and Foreign Commerce Committee.

Public Health Training and Services

Senators Hill (D., Ala.), Ives (R., N. Y.), Kennedy (D., Mass.), McNamara (D., Mich.), and Cooper (R., Ky.) have introduced, in S. 2580, a measure which would authorize an amount, not to exceed 1 million dollars (out of the 30 million dollars already authorized), to enable the surgeon general to make grants-in-aid under terms and conditions prescribed by regulation. The purpose of the grants would be for the support of public or nonprofit educational institutions which provide comprehensive professional training, specialized consultative services, and technical assistance in the fields of public health and in the administration of state and local public health programs. This measure was referred to the Labor and Public Welfare Committee.

Representative Macdonald (D., Mass.), in H. R. 8862, has introduced a measure identical to that of Senator Humphrey (D., Minn.), in S. 2304, previously reported. These measures would provide "an emergency five-year program of grants and scholarships for post-graduate education in the field of public health." Representative Macdonald would authorize the following appropriations: 1. One million dollars annually to make payments to schools to assist in maintaining and increasing their enrollment of graduate students. These funds could be used for "establishing, maintaining, and enlarging staffs and in maintaining and operating their facilities (including the acquisition of equipment) for such training." Payments would be made on the basis of 15% of the basic operating costs of graduate instruction plus $500 for each full-time student in excess of 30 students, plus $500 for each full-time student in excess of the average past enrollment. The total payment, however, could not exceed 50% of the basic operating costs of the school. 2. One million dollars annually for five years for construction and equipment grants not to exceed 50% of the cost of equipment. 3. A total of $1,500,000 over a six-year period for scholarships. This measure was referred to the Committee on Interstate and Foreign Commerce.

Additives in Food

Representative Wolverton (R., N. J.), in H. R. 8629, has introduced a measure which would prohibit the use of additives in food that have not been adequately tested to establish their safety. The pretesting data would have to be submitted to the Secretary for a reasonable period of time to evaluate such data before the additive could be used. This bill was referred to the Interstate and Foreign Commerce Committee.

Representative Farbstein (D., N. Y.), in H. Res. 311, proposes to "establish a select committee to conduct a full and complete investigation and study of the use of chemicals and other additives in food, medicine, and beverages to ascertain what deleterious effects such chemicals have on human life and health." This bill was referred to the Rules Committee.

Liberalization of Social Security Amendments

Representative Perkins (D., Ky.), in H. R. 8774, proposes to liberalize the Social Security Act to (1) increase the base upon which the social security tax is levied from $4,200 to $6,000 annually; (2) increase the maximum monthly benefits for an individual from $108.50 to $138.50 per month; (3) increase the minimum monthly payments from $30 to $35 per individual; (4) reduce the retirement age

---

From the Washington Office of the American Medical Association.

to 60 years for both men and women (the present requirement age is 65 years for men and 62 years for women); (5) reduce to 50 years the age at which widows could receive full benefits; (6) reduce requirements for disability payments to simply the standards for being fully insured, that is, coverage for 40 quarters or one-half the quarters since 1950, with a minimum of 6 quarters (the present law requires that an individual be fully insured, insured currently [1½ years out of previous 3 years] and have been insured 5 out of the previous 10 years) and (7) repeals the section in the present law which requires that a person entitled to disability benefits would have his payments reduced by the amount received from other governmental pension plans or workmen's compensation law or act of physical or mental impairment.

Representative Kean (R., N. J.), in H. R. 8883, would amend the Social Security Act in a number of ways to: (1) include compulsory coverage of physicians under Old Age and Survivors Insurance; (2) provide benefits for dependents during the periods of disability when the worker is unable to engage in substantial gainful activity, equivalent to benefits at retirement (if the worker refused rehabilitation, the benefits to dependents would be denied); (3) authorize payment for rehabilitation services for the disabled worker from the disability trust fund; (4) increase the maximum monthly benefits for covered individuals from $108.50 to $118.50, for married couples without children from $162.80 to $177.25, maximum family benefits would be raised from $200.00 to $271.25, and widows and widowers monthly payments would be raised from $81.40 to $94.80; (5) raise the maximum family benefits for widows and their dependent children from $200.00 to $296.25; (6) raise the base wages subject to tax from $4,200 to $4,800 annually (no increase in rates is proposed; by 1975, the self-employed physician [if by then covered] would pay the scheduled 6⅜% on $4,800 or $306 a year); (7) increase 1% per year over present benefit levels for those who delay retirement beyond 65 years until 72 years of age is reached. Thus, the retired worker who delayed retirement until age 72 could receive an additional $8.33 monthly or a total of $126.83 instead of $118.50. Both measures were referred to the Ways and Means Committee.

Committee to Study Federal-State Grants

Representative Bow (R., Ohio), in H. Res. 302, and Representative Landrum (D., Ga.), in H. Res. 312, have introduced identical measures which propose to create a select committee of the House to study activities in which the federal government extends aid to state and local governments, individual agencies, or to individuals "to determine (1) what justification now exists for Federal aid in any field; (2) and in what fields of activity existing programs of aid should be continued, or increased, or terminated; (3) whether new programs of aid should be started; (4) the impact of Federal grants-in-aid programs upon beneficiary States as to internal politics, economics, administrative structure, and local incentives and independence; (5) the future ability of States and the Federal Government to finance activities usually the subject of such grants; and to make such recommendations as it deems advisable."

Representative Pelly (R., Wash.) proposes, in H. Res. 318, to authorize the Ways and Means Committee to study desirability of discontinuance by the government of levying and collecting certain taxes, giving the states priority in such fields. These bills were referred to the Rules Committee, which reported in favor of H. Res. 312, and increased the members of the select committee from five to nine.

Study Commission on Problems of the Blind

Representatives Wainwright (R., N. Y.), in H. R. 8427, and Elliott (D., Ala.), in H. R. 9055, have introduced identical measures which propose to establish a Presidential Study Commission on Problems of the Blind. This measure has the support of the Administration and would authorize the President to appoint 21 members from among persons with knowledge of and interest in problems of the blind. Leaders in medicine, education, social work, psychology, rehabilitation, and related professions and volunteer agencies and the public would be represented. At least three of the members must be blind persons. The commission would make a broad and comprehensive study of programs and activities relating to blindness and the needs of blind persons. Two hundred thousand dollars annually would be authorized for the expenses of the study, which must be completed in three years. This measure was referred to the Committee on Education and Labor.

Medical Care in Alaskan Military Hospitals

Delegate Bartlett (D., Alaska) has introduced, in H. R. 8944, a measure which would authorize, in the Army and Air Force hospitals and dispensaries outside the continental limits of the United States and in Alaska, the same services, for all military personnel and their dependents and other specified civilians, now given in the naval and Marine Corps medical facilities. The bill would amend the present law to read as follows:

> In addition to those persons, including the dependents of Armed Forces personnel, now authorized to receive hospitalization at Army, Navy, or Air Force hospitals, hospitalization and dispensary service may be provided at Army, Navy, or Air Force hospitals and dispensaries outside of the continental limits of the United States and in Alaska, to officers and employees of any department or agency of the Federal Government, to employees of a contractor with the United States or his sub-contractor, to the dependents of such persons, and in emergencies to such other persons as the Secretary of the military department concerned may prescribe: Provided, That such hospitalization and dispensary service to other than the dependents of the Armed Forces

personnel shall be permitted only where facilities are not otherwise available in reasonably accessible and appropriate non-Federal hospitals. The charge for hospitalization or dispensary service for persons other than dependents of Armed Forces personnel as specified in this section shall be at such rates as the President shall from time to time prescribe, and shall be deposited to the credit of the appropriation or fund for the maintenance and operation of Army, Navy, or Air Force hospitals.

This measure was referred to the Armed Services Committee.

Studies for Older Persons

Representative Flood (D., Pa.) proposes, in H. R. 9025, to authorize, over a six-year period, federal grants of $154,560,000 to states, public and nonprofit institutions, and organizations to assist in the development and operation of studies and projects to help solve the problems of older persons through projects which will help—

(1) older persons to secure gainful employment, including self-employment in their own businesses;

(2) older persons to enjoy retirement income sufficient to support a reasonable and improved standard of living;

(3) provide older persons, so far as possible, the opportunity of living in their own homes, or, if they so desire, in suitable private or public facilities;

(4) older persons to receive adequate preventive and therapeutic medical and dental care, and hospital, surgical, nursing, and other health services;

(5) make voluntary hospital and medical-care-insurance protection available to all older persons;

(6) make available opportunities for rehabilitation which will restore to independent useful lives older persons who are physically or mentally disabled;

(7) provide services such as counseling, information, adult education, vocational retraining, recreation, and social casework for individuals who are planning for retirement or need such services in their later years;

(8) increase research in geriatrics and other aspects of aging; and

(9) train personnel necessary to provide specialized services to older persons in the fields of medicine, dietetics, nursing, psychology, counseling, education, recreation, social work, and in such other fields as will carry out the purposes of this Act.

This measure was referred to the Education and Labor Committee.

Regulation of Hazardous Substances for Household Use

Senator Bush (R., Conn.), in S. 1900, and Representative Williams (D., Miss.), in H. R. 9063, have introduced virtually identical measures t regulate the interstate distribution and sale of packages of hazardous substances intended for household use to insure proper labeling. The labe would carry such words as: "dangerous," "warning," "caution," and "keep this out of the reach o children," and would also suggest first-aid treatmen to minimize injury until medical attention could b secured. These measures were referred to the respective Interstate and Foreign Commerce Committees.

COUNCIL ON MEDICAL SERVICE

HEALTH MAINTENANCE FOR THE OLDSTER

Henry A. Holle, M.D., Austin, Texas

This is the fourth of a series of papers on various aspects of aging. Each paper has been prepared for the Committee on Aging by an authority in the field. When completed, the series will be published in booklet form.

The immediate past-president of the American Medical Association, Dr. Dwight H. Murray, in his address in Chicago last year said: "I sincerely believe that it is Nature's plan that we remain physically and mentally alert to the end of our days." Surely there are none who would dispute the desirability of such a favorable outlook for the future.

It is evident that as time goes on people will live longer. But it is not enough to live so that one might be enabled to wait for death. Life should provide such priceless ingredients as physical and mental health and well-being—the will to live. During the Federal-State Conference on Aging in Washington, D. C., in June 1956, it was stated that the Council of State Governments had compiled a "Bill of Objectives for Older People."

This list included such items as physical and mental health, including rehabilitation; equal opportunity to work; home living; adequate minimum income; participation in community activities; freedom, independence, and initiative. One will observe that these objectives are no different from those to

---

Commissioner of Health, Texas State Department of Health.

Members of the Committee on Aging are Drs. H. B. Mulholland, Chairman, Charlottesville, Va.; Edward L. Bortz, Philadelphia; Henry A. Holle, Austin, Texas; Wingate M. Johnson, Winston-Salem, N. C.; Theodore G. Klumpp, New York; Frederick C. Swartz, Lansing, Mich.; and Cecil Wittson, Omaha. Committee Staff: Mr. George W. Cooley, Secretary, and Mr. Herbert B. Norton, Research Assistant.

h any of us would aspire. But, in my judgment, maintenance of physical and mental health is lamental to the other objectives mentioned.

s physicians, we are quick to agree that in health itch in time saves nine." But our attention has too n been drawn away from the person who, for the nent, at least, was not ill. We have concerned elves almost exclusively with those who comned of symptoms and who needed relief. This took of our time. Moreover, we have always been reant to risk being placed in the position of seeming olicit business.

ll of these reasons for our failure to take action in field of health conservation are understandable. we should now take a more positive approach to lth maintenance in our oldsters. Keeping well is portant to all of us. It is the key basic need in older groups. The interest of the apparently well senior zen in his own health has been grossly underestited. Our work is thereby made easier.

or many years we have ignored the so-called deierative or chronic diseases in the elderly. We acoted them as matters of course in the treatment of re acute symptoms. Now our researchers are study g tissue cells to find out why their rate of replacent slows down with increasing age. Who can say it these mysteries will not be solved? Who can say it atherosclerosis may not some day be reversible, at least preventable?

Because of these things, we see a beginning realizan on the part of physicians in practice and in health encies that the development and application of regiens of health maintenance in our oldsters can be mendously productive. If we take this positive apoach to the "stitch in time" philosophy, we may oid being faced with the necessity of doing a comete sewing job later on when it can do little good.

Too much emphasis cannot be placed upon the need r a medical advisor in the middle and senior years. e need here the individual physician-patient relanship. It pays its greatest dividend during the years ien body reserves are dwindling and when advange should be taken by the physician of intimate owledge of the individual patient gained through ars of experience as his medical advisor.

Like the management of diabetes, health maintence in the oldster, or the science of keeping him ell, is a long-range undertaking. It must, of necessity, t be limited to the treatment of symptoms when they ise. The approach must be one of sympathetic undernding of what makes him "tick" and an interest in s over-all health problems. One need not add that must be made to feel that his physician is sincerely terested in him as an individual.

This interest should include such fundamentals of od health as his home; the food he eats; his personal ing and recreation habits; outlook on life and movation for living; and the avoidance of fatigue. Other ticles in this series discuss in more detail a number these keystones of life and health maintenance of e oldster. How then does one keep him well?

Our colleagues in pediatrics have long used the "well baby clinic" as a productive device to insure optimum health maintenance in young children. As yet we have scarcely scratched the surface in utilizing this technique in our senior citizens. The "well oldster clinic," properly managed, will yield a far richer source of things that need doing. The doctor's office is the best place for this activity. The conditions most commonly uncovered are cardiovascular disease, cancer, arthritis and rheumatism, mental diseases, nephritis, glaucoma, diabetes, obesity, anemia, and loss of vision and hearing. Ironically, some of these conditions might well have been the targets in a program of health maintenance during the early and middle years.

In this connection it seems somewhat inconsistent for us to express concern over the health of the preschool child, with a little more attention to his health through the elementary school grades, only to forget about him later. At junior-high-school age, he then is assumed to have achieved an Achilles-like state of physical and mental well-being, receiving no more frequent and directed medical supervision, except during periods of acute illness. Finally, when his body and mind have become worn with the fatigue of a half-century of struggle in a highly competitive and industrialized society, we again express a concern for his infirmities which we refer to as chronic diseases of old age.

The conditions found in the oldster may loom as formidable obstacles to the joy of living unless we begin a carefully managed program of secondary prevention. By secondary prevention we no longer mean the prevention of the condition itself, but rather a regimen to minimize its adverse effect. Secondary prevention is a positive program of hopeful action—a refusal to subscribe to the negative outlook which, in too many minds, is reconciled to the futility of effort.

Those who work with these patients know that the potential harvest of accomplishment is very great. But each case calls for a long-range plan of management, and the physician is the key to its success. The patient must learn to live with what he has left. But the more we are able to conserve his health resources, the more effectively he will be enabled to carry on as an active oldster.

It is not my purpose to describe the clinical procedures which are necessary to achieve health maintenance. Many of the elements of such a program are covered in other articles in this series. Each patient must be managed somewhat differently, according to his own needs. Medical or surgical procedures, if they are necessary, should not be avoided purely on the basis of age.

There should be sufficient flexibility to permit changes in living habits in the light of what develops with the further passage of time. Periodic reappraisals will be necessary and good records are essential. The entire program is designed to provide the maximum activity and participation permissible

Activity and participation in the living process are vital essentials in the life of the older person. Most of us have observed that sudden retirement without adequate preparation is a killer of men. Inactivity breeds depression and loneliness; death, too often, soon follows in their wake. Life must go on and there must be people to share it with; there must be things to do.

Our systems of mandatory retirement based on chronological age are not consistent with our other efforts to conserve human resources. As our methods of measuring productive capabilities of people become objective and reliable, the policy of sudden forced retirement will, in all likelihood, give way to a more gradual reassignment of duties in keeping with variations in the physical and mental aptitudes of individual employees.

We stress productive activity because of its importance to health maintenance in the oldster. This is especially true of mental health. One cannot stand still. As time moves on we either go forward or backward. Unless, over the years, we have prepared for retirement through the development of a hobby or an avocation, the sudden cessation of a lifelong activity makes a disastrous impact on our well being. For these reasons, many oldsters will need to be referred to day-centers for recreational activities or to a so-called sheltered workshop for productive work. The physician will wish to utilize these and other facilities for time consuming educational and ancillary services for his patients.

Public health agencies are giving top priority to chronic diseases, and many other agencies are also providing increased services for the aging. These activities will result in many referrals to private physicians for diagnosis and treatment. It is my hope that we as physicians will meet this challenge through the individualized approach which has distinguished the practice of medicine in the United States.

SPECIAL COMMITTEE ON INFLUENZA

COMMITTEE ON DISEASE REPORTING AND EPIDEMIC SURVEILLANCE

The Surgeon General of the U. S. Public Health Service called a special meeting of state and territorial health officers in Washington, D. C., on Aug. 27-28, 1957, to discuss and otherwise consider national and community plans to cope with Asian influenza. Members of the A. M. A. Special Committee on Influenza participated in the two-day meeting. Here are some of the recommendations adopted by this group.

Frank W. Barton, *Secretary.*

The important laboratory work lies in the substantiation of an epidemic and is of little value to the individual patient. In the identification of an outbreak, throat washings and paired serums should be submitted from at least 12 clinical cases. Accompanying the specimens should be a clinical abstract and data on how specimens were taken. In the face of an explosive outbreak of upper respiratory illness the specimens should be gathered within the first three days of illness and submitted through the state health authority.

Technical information on securing and preparing specimens together with restrictions should be disseminated through state channels. Local health authorities should participate in the evaluation of an epidemic situation in accordance with existing policy.

It is recommended that the several states plan to gather intelligence rapidly regarding the occurrence of pneumonia. Since bacterial identification by sputum specimen is as important as virus diagnosis, it is further recommended that sputum specimens for bacterial study, as well as antibiotic sensitivity, be taken as soon as pneumonia is suspected. The pneumonia rate in the extremes of age should be used as a sensitive index to assess the severity of an epidemic.

It is recommended that each state submit a week ly situation report to the Public Health Service fo operational purposes. It is further recommende that the states adopt a program of (1) epidemi reporting by counties to the states and then to th Public Health Serivce; (2) adoption of a standar method of gathering and reporting information o outbreaks; and (3) sampling of absentee rates i selected schools and industries.

In order to facilitate analysis of data gathere and to aid local, state, and national managemen of the epidemic, states are urged to participate i the proposed Public Health Service surveillance an reporting programs.

It is recommended that as much useful informa tion should be gathered in an epidemic investi gation as possible and should include, but not b limited to, symptoms and etiology as determine by laboratory confirmation on a representativ sampling, complications and mortality, and ag groups involved. Suggested forms for gatherin useful information in organized fashion are bein developed by the subcommittee on epidemic intelligence and the Public Health Service. Therefore these forms are commended to the states for organizing and reporting such information as they are able to obtain.

It is recommended that assistance be provided from the Public Health Service in support of virus laboratories in state health departments to include diagnostic materials and training of laboratory personnel. Further, the providing of aid in epidemiological personnel by the Public Health Service to the states at the latter's request is recommended. The Public Health Service should assist the states by planning for future conferences concerning epidemic progress as seem to be needed.

Committee on Vaccination Promotion

What should be the primary objectives emphasized in vaccination promotion programs?

The primary objective in promoting vaccine programs is to prevent illness and death from epidemic influenza within the limits of available vaccine.

Should there be a system of interstate allocation of influenza vaccine?

We recommend that there be a system of interstate allocation of vaccine based on a voluntary agreement with the manufacturers.

What priorities, if any, should be established for influenza vaccination and how and by whom should these be determined?

RESOLVED that the surgeon general of the Public Health Service recommend to civilian physicians that they give priority to: (1) those individuals whose services are necessary to maintain the health of the community; (2) those individuals necessary to maintain other basic community services; (3) persons with tuberculosis and others who in the opinion of the physician constitute a special medical risk; and be it further

RESOLVED that the Committee on Influenza of the A. M. A. take such action as necessary to assist in implementation of these recommendations.

Whereas other basic community services vary from place to place, be it resolved that each level of government be encouraged to establish advisory committees broadly representative in nature to consider which groups are deemed essential to maintain necessary services.

What recommendations should be made regarding vaccination of children?

Administration of influenza virus vaccine containing the Asian strain is approved for use in children and it may be initiated at about three months of age. From experience with earlier vaccines evidence has been obtained that a somewhat better antibody response can be obtained in children if the vaccination is given in two injections instead of one. The doses recommended are as follows:

For preschool-age children (3 months to 5 years)—0.1 cc. intracutaneously or subcutaneously, repeated after an interval of one to two weeks.

For children 5 to 12 years of age—0.5 cc. subcutaneously, repeated after an interval of one to two weeks. For children of 13 years of age and older, the dose for adults (1.4 cc. subcutaneously in a single injection) may be used.

MEDICINE AND THE LAW

PATIENT'S RIGHT TO PRIVACY

This is the second in a series of six articles dealing with the necessity for and proper format of certain medicolegal forms. The subjects to be covered are (1) consent to operations and other medical procedures; (2) patient's right to privacy; (3) confidential communications and records; (4) artificial insemination; (5) the physician-patient relationship; and (6) autopsy.

This material has been prepared and will be published in book form by the Law Department of the American Medical Association under the title "Medicolegal Forms with Legal Analysis." The book will include extensive legal citations and a substantial number of additional forms which have not been included in this series of articles.—ED.

In recent years there has been a trend among the courts to provide a remedy, in the form of an action in tort, for the violation of an individual's right of privacy. The individual has a right to be "left alone" and not be subject to unwarranted and unwanted publicity, with possible attendant shame, mortification, and humiliation.

A patient has the same right of privacy that any other individual has. He has a right to have information relating to his condition kept secret and not made the subject of publicity. When a patient disrobes for an examination, operation, or any other medical procedure, he does so for the professional benefit of the physician and he does not expect to be subjected to the examination of other persons, medical or nonmedical, who are not necessary to the carrying out of the medical procedure. The admission of nonessential persons, without the specific consent of the patient, constitutes a violation of the patient's right of privacy. Nor does the patient, when he submits to a medical procedure, consent to the taking of his picture for future publication. The unauthorized taking of pictures of the patient, even though they have not been published, will give rise to a cause of action. One of the most frequent violations of a patient's right of privacy is the unauthorized use of his picture. It is immaterial that the patient's condition is made public because it is newsworthy and of interest to the public or that unessential persons are permitted to observe the patient or pictures of the patient are taken and published for the purpose of advancing medical science or educating the public.

The attorney general of New York made the following answer to the state department of health's question whether it could, legally, present an educational exhibit of "before and after" pictures of cancer patients at the state fair: "It is my opinion that you may not legally make use of these photographs for the purpose of public display as set forth in your letter, without the consent of the subjects of the photographs, if they are of living persons. While it is true that the contemplated use may have a distinct social value for the general instruction and information of the public, yet I believe that the unauthorized use of such pictures is barred by the provisions of the statute. . . . The unfortunate person afflicted with a malignant disease such as cancer may very well have a perfectly natural and readily understandable aversion to having a photograph or picture showing his condition displayed before the public." Publicity may be given to the patient's condition, observers may be admitted, and pictures may be taken and published only as specifically consented to by the patient. To facilitate proof, if such should become necessary, the consent should be in writing. It should state specifically just what it is that the patient consents to with respect to observers, pictures, etc. If there are any restrictions or limitations on the consent they must be strictly observed.

In addition to having his right to privacy respected by the physician, the patient has a right to receive from the physician, at all times, decent and respectful treatment.

FORM 1.—*Authority to Admit Observers*

PATIENT'S NAME.. AGE........ DATE........

I hereby grant authority to Dr. ....

and to .... Hospital to permit the presence of such observers as they may deem fit to admit in addition to physicians and hospital personnel, while I am undergoing (operative surgery) (childbirth), examination, and treatment.

Signed..

Witness..

FORM 2.—*Consent to Taking of Photographs*

In connection with the medical services which I am receiving from Dr. ...., I consent that photographs may be taken of me or parts of my body, under the following conditions: (1) The photographs may be taken only with the consent of my physician or surgeon and under such conditions and at such times as may be approved by him. (2) The photographs shall be taken by my physician or by a competent photographer, approved by my physician. (3) *These photographs shall be used for medical records only, unless, in the judgment of my physician, medical research, education, or science will be benefited by their use. In that event I agree that they may be used for such purposes, provided that my identity is not revealed by the photographs or by descriptive texts accompanying them.*

Signed ....

Date ....

....

Witness

FORM 3.—*Consent to Publication of Photographs*

PATIENT.................................. PLACE...................... DATE........

1. I hereby authorize Dr. .... and such assistants, photographers, and technicians as he may engage for this purpose, to take such photographs of me *as he may desire* before, during, and after the operation which is to be performed upon me on or about......................

.... 19........, and to permit such photographs to be published *and republished in professional journals* and medical books or to be used for *any other purpose* which he may deem fit in the interest of medical education, knowledge or research.

2. Authority is further given to permit the modification or retouching of the aforementioned photographs, and to the publication of information relating to my case, either separately or in connection with the publication of the photographs taken of me.

3. Although I give permission to the publication of all details and photographs concerning my case, it is specifically understood that I will not be identified by name.

Signed ....

Witness ....

FORM 4.—*Consent to Televising of Operation*

PATIENT................................ PLACE.................... DATE...........

In the interest of medical education and knowledge, I hereby consent to the televising of the operation which is scheduled to be performed upon me on or about...................

.... 19......... I hereby authorize Dr. ....

and the .... Hospital to admit to the operating room, the cameramen and technicians who are to participate in the televising of this operation, in addition to the usual hospital staff.

Signed ....

Witness ....

FORM 5.—*Consent to Taking of Motion Pictures of Operation*

PATIENT................................ PLACE.................... DATE...........

1. I hereby consent to the taking of motion pictures of the operation which is scheduled to be performed upon me on or about .... 19......... I authorize Dr. .... and the .... Hospital to admit to the operating room, the cameramen and technicians who will participate in the filming of this operation.

2. I hereby and forever waive all rights that I may have to any claims for payment or royalties in connection with any exhibition, televising, or other showing of this motion picture film, regardless of whether such exhibition, televising, or other showing is under philanthropic, commercial, institutional, or private sponsorship, and irrespective of whether a fee of admission or film rental is charged.

3. I grant this consent as a voluntary contribution in the interest of medical education and knowledge and subject only to the condition that I will not be identified by name in this motion picture film.

Signed ....

Witness ....

MEDICAL NEWS

CALIFORNIA

Grants for Cardiovascular Studies.—The American Heart Association, in support of their studies of heart and blood vessel diseases, has awarded grants totaling $149,792 to 24 scientists from California. The awards are among 225 national grants-in-aid totaling $1,395,285. Largest of the grants, $8,600, went to Dr. Arthur Selzer and Dr. Forrest Willett, of Veterans Administration Hospital, Fort Miley, for a fellowship to Dr. David Y. Naruse, of San Francisco, who will do research to clarify the mechanisms responsible for cardiac shock and test the effects of various drugs in overcoming cardiac shock.

Cardiovascular Research Institute.—Dr. Julius H. Comroe Jr. medical researcher and educator, has been named director of the Cardiovascular Research Institute at the University of California Medical Center, San Francisco. Dr. Comroe comes from the University of Pennsylvania Graduate School of Medicine, Philadelphia, where he was chairman of the department of physiology and pharmacology. He has been appointed a professor of physiology on the University of California faculty.

The institute will be devoted to an intensive, many-phased research attack on diseases of the heart and circulatory system. Quarters for the institute are being built on the 13th floor of Herbert C. Moffitt Hospital and are to be ready for occupancy next July. Several research programs are already in progress, however. Dr. Comroe has served on numerous research and advisory committees of scientific organizations and from 1944 to 1946 was a medical research consultant to the Army. In 1956 he became chairman of the Physiology Study Section of the U. S. Public Health Service. He is currently president of the Laennec Society and a councillor of the American Physiological Society.

COLORADO

State Medical Society Meeting.—The 87th annual session of the Colorado State Medical Society will be held Sept. 24-27 at the Shirley-Savoy Hotel, Denver. The presidential address will be given by Dr. Gatewood C. Milligan, of Englewood. Roundtable discussions and luncheons will be held Sept. 25 and Sept. 26. On Sept. 27 "the Practicable Aspects of Professional Liability; A Medicolegal Clinic," will be conducted with Edwin J. Holman, LL.B., Chicago, serving as guest moderator. A special program by the law department of the American Medical Association and the Medicolegal Committee of the Colorado State Medical Society will be held Sept. 27. A symposium on "What Has Been Done in Colorado" will be conducted by Drs. Monroe Tyler, Denver, Henry Thode, Fort Collins, and Mason Light, Gunnison. Entertainment includes a banquet the evening of Sept. 26. Technical exhibits are planned. For information write the Colorado State Medical Society, 835 Republic Building, Denver 2, Colo.

ILLINOIS

Chicago

Research Award.—The Dr. Morris L. Parker award, given annually upon recommendation of the faculty of the Chicago Medical School for meritorious scientific research, was conferred this year on Abraham R. Goldfarb, Ph.D., assistant professor of biochemistry, and Waldemar Dasler, Ph.D., also an assistant professor of biochemistry. Dr. Dasler received the award because of his studies having to do with lathryism. Dr. Goldfarb was given the award because of his work in connection with the isolation of a master chemical in ragweed pollen. The award, $500, was made during the recent commencement.

Clinic for Headache Studies.—A clinic has been opened as part of the Chicago Medical School's neurological clinic at Mt. Sinai Hospital at which studies will be confined to the severe and persistent headache in an attempt to discover its possible relationship to the more severe forms of mental illness. Patients are referred to the clinic only from other departments of the hospital, after preliminary interview in the neuropsychiatric department of the Medical School. After neurological, psychiatric, and physiological tests, they are enrolled in the headache clinic for study and treatment or other type of therapy needed to fit the diagnostic impression. Dr. Louis S. Schlan heads the project. The clinic, made possible by a grant from Sandoz Pharmaceutical Company, will be held Monday mornings from 9:30 to noon.

IOWA

State Academy of General Practice Meeting.—The ninth annual meeting of the Iowa Chapter of the American Academy of General Practice will be held

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Sept. 22-24 at the Savery Hotel, Des Moines. The program includes the following papers by out-of-state speakers:

The Relationship of the GP to Industry, Dr. Charles F. Shook, Toledo, Ohio.
The Postphlebitic Syndrome, Dr. Geza de Takats, Chicago.
Recent Advances in the Etiology of Mild Respiratory Diseases, Dr. Thomas G. Ward, Notre Dame University.
Initial Management of the Seriously Injured Patient, Dr. Claude R. Hitchcock, University of Minnesota, Minneapolis.
Diagnosis of Acute Internal Injuries, Dr. Daniel J. Moos, University of Minnesota.
Surgical Treatment of Varicose Veins and Stasis Ulcers, Dr. Karl Lofgren, Mayo Clinic, Rochester, Minn.

Question and answer periods will follow the formal presentations. Luncheon speakers, Rev. Granger Westburg, Chicago, and Mr. Walter L. Stewart, attorney at law, Des Moines, will speak on "Problems Related to Medicine and Religion," and "Wills, Taxes, and Money," respectively. The E. E. Shaw Memorial Lecture, "Forceps Delivery," will be given by Dr. William C. Keettel, State University of Iowa, Iowa City. A panel discussion, "Obstetric Problems," will be conducted the afternoon of Sept. 24 with Dr. Keettel as moderator. Entertainment includes the annual banquet, Sept. 23. A special ladies' program is planned.

NEW YORK

Conference on Animal Diseases and Health.—"Animal Diseases and Human Health" was the subject of a joint conference of the New York Academy of Sciences and the Communicable Disease Center in New York City, recently. The center is a division of the Bureau of State Services, Public Health Service, U. S. Department of Health, Education, and Welfare, with headquarters in Atlanta, Ga.

The conference provided a 10-year progress report on the zoonoses. Diseases such as psittacosis, brucellosis, cat scratch fever, rabies, anthrax and encephalitis were reviewed.

Other diseases were discussed from the standpoint of possible relationship to similar conditions in man, such as pulmonary adenomatosis, which is reported to have been decimating sheep flocks in many parts of the world and has several factors in common with lung cancer in humans. For information write Medical and Pharmaceutical Information Bureau, Inc., 115 East 69th St., New York City.

New York City

Tumor Transplantation Techniques.—A three-day session on the techniques and problems associated with the heterologous transplantation of human tumors will be held Oct. 8-10, at the Sloan-Kettering Institute. Besides the lectures, personal opportunity to work with various transplantable human tumors and a variety of animal hosts as well as embryonated eggs will be available. Tissue cultures derived from the transplantable human neoplasms will also be demonstrated. The value of these tumors in various research programs will be discussed. The session will be given by Drs. H. Toolan, David Karnofsky, Alice Moore, George Woolley, J. Harris, and other associates. For information write Helene W. Toolan, Ph.D., Sloan-Kettering Institute, 410 East 68th St., New York City. There will be no charge.

OREGON

General Practice Meeting in Portland.—The 10th annual meeting of the Oregon Academy of General Practice will be held Sept. 26-27 at the Multnomah Hotel, Portland. Luncheon panel discussions will be held at noon on both days. The program includes the following topics by out-of-state speakers:

Certain Aspects of the Control of Inflammatory Conditions in the Urinary Tract, Dr. Ian Thompson, Ann Arbor, Mich.
The Problem of Adenomyosis, Dr. Ralph C. Benson, San Francisco.
Fats, Cholesterol and Atherosclerosis, Dr. Norman Jolliffe, New York City.
Common Errors in Diagnosis of Early Cancer, Dr. N. Frederick Hicken, Salt Lake City.

Technical exhibits are arranged. Guest speaker at the annual banquet, Sept. 26, will be Dr. John S. DeTar, Milan, Mich. For Information write Mrs. Anna Payne, Executive Secretary, Oregon Academy of General Practice, 4942 N. E. Thirty-Fourth Ave., Portland 11, Ore.

PENNSYLVANIA

State Medical Society Meeting.—The 107th annual session of the Medical Society of the State of Pennsylvania will be held Sept. 17-21 at the Penn-Sheraton Hotel, Pittsburgh. Panel discussions and moderators to be presented at the general sessions include the following: Hyperthyroidism, Dr. Isidor S. Ravdin, Philadelphia; Resistant Hospital Infections, Dr. Russel B. Roth, Erie; Use and Misuse of the Hospital Bed, Dr. Samuel P. Harbison, Pittsburgh; Diagnosis and Treatment of Early Heart Failure, Dr. Wendell B. Gordon, Pittsburgh; and Common Precancerous Lesions, Dr. John W. Shirer, Pittsburgh. The following papers will be presented by out-of-state speakers:

Peptic Ulcer, Dr. Keith S. Grimson, Durham, N. C.
Hypnosis and Its Medical Indications, Dr. William S. Kroger, Evanston, Ill.
Drug Addiction, Dr. Guy H. Williams, Cleveland.
Cardiac Surgery, Dr. Alfred Blalock, Baltimore.
Carcinoma of the Colon, Dr. Richard K. Gilchrist, Chicago.
The Clinical Spectrum of Pyelonephritis, Dr. George E. Schreiner, Washington, D. C.

Question and answer periods will follow the formal presentations. Scientific and technical exhibits are planned. Entertainment includes a golf tournament and dinner, Sept. 16. A special ladies' program has been arranged. For information write Dr. Harold B. Gardner, 230 State St., Harrisburg, Pa.

GENERAL

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Winners of Ophthalmology Fellowships.—Five additional physicians who are beginning their residency training in ophthalmology have been announced as the 1957 winners of fellowships provided by the Ophthalmology Scholarship Fund of the Guild of Prescription Opticians of America, Inc. Each fellow will receive $1,800 paid in monthy stipends over the three years of residency training. This year's fellowship recipients and the institution in which each will serve his residency are: Dr. Donald P. Tucker, of Erie, at Massachusetts Eye and Ear Infirmary, Boston; Dr. Milton Boniuk, of Glace Bay, Nova Scotia, Canada, at Wills Eye Hospital, Philadelphia; Dr. Henry T. Edmondson Jr., of Pineview, Ga., at the Medical College of Georgia, Augusta; Dr. John A. Emerson, of Delray Beach, Fla., at Northwestern University Medical School, Chicago; and Dr. George K. Edwards, of Sudbury, Ontario, at Royal Victoria Hospital, Montreal.

CORRECTION

Micrococcic Infections.—In the article "Micrococcic (Staphylococcic) Infections in a General Hospital," in the Aug. 17 issue of The Journal, pages 1733-1739, the first sentence in the last paragraph of the summary should have read "Most of the micrococcic infections which appeared during hospitalization or shortly after discharge were probably the result of cross-infection within the hospital." As printed, the word "probably" was inadvertently omitted.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 17-19. Sec., Dr. D. G. Gill, State Office Building, Montgomery 4.

Arizona:° *Examination and Reciprocity.* Phoenix, Oct. 16-18. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:° *Examination and Reciprocity.* Little Rock, Nov. 7. Sec., Dr. Joe Verser, Harrisburg.

California: *Written Examination.* Sacramento, Oct. 21-24. *Oral Examination.* San Francisco, Nov. 16; *Oral and Clinical for Foreign Graduates.* San Francisco, Nov. 17. Sec., Dr. Louis E. Jones, 1020 N St., Sacramento 14.

Colorado:° *Reciprocity.* Denver, Oct. 8. *Examination.* Denver, Dec. 3-4. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Connecticut:° *Examination.* Hartford, Nov. 12-14. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic. Examination.* Derby, Sept. 10. Sec., Dr. Donald A. Davis, Derby.

Delaware: *Examination.* Dover, Jan. 14-16. *Reciprocity.* Dover, Jan. 23. Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:° *Reciprocity.* Washington, Sept. 9. *Examination.* Washington, Nov. 12-13. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington, D. C.

Florida:° *Examination.* Miami, Nov. 24-26. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination.* Atlanta, Oct. 8-9. *Reciprocity.* Atlanta, Oct. 10. Sec., Mr. Cecil L. Clifton, 111 State Capitol, Atlanta 3.

Idaho: *Examination and Reciprocity.* Boise, Jan. 13-15. Ex. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Iowa:° *Examination.* Des Moines, Dec. 2-4. Exec. Sec., Mr. Donald V. Saf, State Office Building, Des Moines 19.

Kentucky: *Examination.* Louisville, Dec. 9-11. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maine: *Examination.* Portland, Nov. 12-14. *Reciprocity.* Portland, Nov. 12. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Reciprocity.* Baltimore, September. *Examination.* Baltimore, Dec. 10-13. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, Jan. 14-17. Sec., Dr. Robert C. Cochrane, 37 State House, Boston.

Montana: *Examination and Reciprocity.* Helena, Oct. 1-2. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:° *Examination.* Omaha, June. Sec., Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 11-13. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 15-18. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.

New Mexico:° *Examination and Reciprocity.* Santa Fe, Nov. 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 10-13. Sec., Dr. Stiles D. Ezell, 23 South Pearl St., Albany 7.

North Carolina: *Endorsement.* Morehead City, Oct. 12. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 9-12. *Reciprocity.* Grand Forks, Jan. 12. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Endorsement.* Columbus, Oct. 1. *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma: *Examination.* Oklahoma City, Dec. 14-15. Sec., Dr. E. L. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon:° *Reciprocity and Endorsement.* Portland, Oct. 3-5. *Examination.* Portland, January. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Rhode Island:° *Examination.* Providence, Oct. 3-4. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, Dec. 10. Sec., Dr. H. E. Jarvey, Jr., 1329 Blanding St., Columbia.

South Dakota:° *Examination.* Sioux Falls, Jan. 21-22. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:° *Examination.* Memphis, Sept. 25-26. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:° *Examination and Reciprocity.* Fort Worth, Dec. 5-7. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 9-11. Director, Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Reciprocity.* Richmond, Dec. 4. *Examination.* Richmond, Dec. 5-7. Address: Office of the Secretary, 631 First St., S.W., Roanoke.

Washington:° *Examination.* Seattle, Jan. 13-15. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Reciprocity.* Charleston, Oct. 7. *Examination.* Charleston, January. Sec., Dr. Newman H. Dyer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:° *Reciprocity.* Madison, Oct. 18. *Examination.* Madison, January. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Sept. 30, Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Alaska:° On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: *Subject to Call.* Act. Sec., Dr. S. F. Provencher, Agana.

Hawaii: *Examination.* Honolulu, Jan. 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Virgin Islands: *Examination.* St. Thomas, Nov. 13. Sec., Dr. Earle M. Rice, Charlotte Amalie, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Sept. 17. *Reciprocity,* Tucson, Sept. 19. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 7-8. Sec., Mr. S. C. Dellinger, Zoology Department, University of Arkansas, Fayetteville.

Connecticut: *Examination.* New Haven, Oct. 12. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 21-22. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N. W., Washington, D. C.

Florida: *Examination.* Gainesville, Nov. 9. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Iowa: *Examination and Reciprocity.* Des Moines, Oct. 8. Sec., Dr. Elmer W. Hertel, Waverly.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 11-12. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 1-2. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

New Mexico: *Reciprocity.* Santa Fe, Sept. 29. *Examination.* Santa Fe, Oct. 20. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Sept. 27-28. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, Dec. 6-7. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 25-26. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* Austin, October. Chief Clerk, Miss Pearl A. Barrera, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 20 and Milwaukee, Dec. 7. Sec., Mr. William H. Barber, 621 Ransom St., Ripon.

°Basic Science Certificate required.

GOVERNMENT SERVICES

AIR FORCE

Hospital Accreditation Program.—At the close of the 1957 fiscal year, the Air Force has 45 hospitals which are accredited by the Joint Commission on Accreditation of Hospitals—41 within the United States and 4 overseas. During the period of Jan. 1 through June 30, 1957, several of these hospitals underwent a periodic resurvey for an additional three years of accreditation and none of these failed to maintain their accreditation.

ARMY

New Student Dietitian Program.—The chief of the Army Medical Specialist Corps has announced a new Army Student Dietitian Program for women students of home economics. Under this program, which will become effective for the 1957 fall school term, students receive over $200 a month through their last year or two years of college education.

While completing the requirements for a bachelor's degree under this program, students are enlisted in the Women's Army Corps Reserve. On graduation the students are commissioned as second lieutenants in the Army Medical Specialists Corps with the opportunity to participate in the Army dietetic internship. The completion of these two educational programs enables students to be professionally qualified as hospital dietitians.

Obligatory active duty service as a commissioned officer in the Army Medical Specialist Corps for students who participate in these combined programs depends on the amount of time spent in college under the Army's sponsorship. If 12 months or less are spent in a civilian institution, 24 months active service as a commissioned officer are required; if over 12 months, but not more than 24 months, are sponsored in a college, 36 months on active duty are required by the Army.

Additional information may be obtained from the Surgeon General's Office, Department of the Army, Washington 25, D. C., Attention: Personnel Division.

NAVY

Dr. Karsner Honored.—Dr. Howard T. Karsner, medical research advisor to the surgeon general, was elected honorary president of the International Society for Geographic Pathology at the sixth conference of the society in Paris, July 9 through 11. This nongovernmental group aims to study the relations which might exist between diseases and the geographical areas in which they occur.

VETERANS ADMINISTRATION

Rehabilitation of Paraplegics.—A pamphlet, entitled "Occupations of Paraplegic Veterans of World War II and Korea"—the first major study ever attempted of the work experience of paralyzed veterans—is now available through the U. S. Government Printing Office in Washington, D. C., at 35 cents a copy. The Veterans Administration will use it in counseling and planning the vocational rehabilitation training of disabled veterans. It also should be useful to all in the field of rehabilitation and employment of the handicapped, as well as to the handicapped themselves. In a foreword Harvey V. Higley called the study "a vivid demonstration of the resiliency of man, of his tremendous ability to adapt his life to the limitations of a severe physical handicap. . . . Ability is not confined to the able bodied. The disabled, too, can contribute to America, if only they are given the opportunity to do so."

Personal.—Dr. John J. Blasko, former Connecticut commissioner of mental health, has been appointed chief of the VA psychiatry division in the Psychiatry and Neurology Service, Washington, D. C., succeeding Dr. Stewart T. Ginsberg, who left to become commissioner of mental health for Indiana. Dr. Blasko, who served as chief of psychiatric training at the VA Central Office from March, 1952, to May, 1954, is certified in psychiatry by the American Board of Psychiatry and Neurology.

PUBLIC HEALTH SERVICE

Grants for Training Health Workers.—The Public Health Service announced on July 19 the award of grants and awards totaling $1,020,143 to 230 persons, including physicians, engineers, health educators, laboratory workers, dentists, and members of other health professions who will enter colleges and universities this fall for a year of training in public health aspects of their professions. Grants totaling $919,878 also were made to 44 colleges and universities offering public health nursing courses and to 11 schools of public health to assist in the training of students whom the schools select.

This is the second year that public health training funds have been available from the federal government. Last year, under a one million dollar appropriation, the traineeship grants and awards financed the training of 364 public health workers. The purpose is to help relieve the acute personnel shortages in state and local health agencies. In selecting trainees, consideration is given to the professional categories in which personnel shortages are most acute, the age of the candidates, their previous training and experience, and other factors which will increase the supply of young, well-trained workers.

DEATHS

Tonney, Frederick Oscar, Chicago; born in Vinton, Iowa, March 7, 1881; Illinois Medical College, Chicago, 1909; director of laboratories and research for the Chicago Health Department from 1909 to 1931, when he became assistant commissioner in charge of laboratories, serving until 1938; medical officer, Federal Trade Commission, Washington, D. C., 1938-1939; served as director of the City-County Health Department, Escanaba, Delta County, Mich., state health officer for Northern Illinois, District number 2, comprising Lake, McHenry, and Boone counties with offices at Woodstock and Waukegan, Ill., city-county health officer, Mansfield, Richland County, Ohio, medical director, Shelby-Effingham Bi-county Department of Health, Shelbyville, Ill., and health officer, Victoria and Cameron Counties, Texas; on the staff of the Ravenswood Hospital, where he died July 11, aged 76, of bilateral pyelonephritis.

Zillessen, Frederick Otto ⊕ Philadelphia; born in Passaic, N. J., Sept. 16, 1902; University of Pennsylvania School of Medicine, Philadelphia, 1926; certified by the National Board of Medical Examiners; specialist certified by the American Board of Pathology; member of the College of American Pathologists; founding fellow of the American Society of Clinical Pathologists; fellow of the American College of Physicians; past-president of the Pennsylvania Association of Clinical Pathologists; formerly vice-president of the Northampton County Medical Society; served as fellow in pathology at the Mayo Foundation, Rochester, Minn.; from 1931 to 1947 pathologist and pathological consultant at Easton (Pa.) Hospital, Warren Hospital, Phillipsburg, N. J., and Monroe County General Hospital, East Stroudsburg; director of laboratories at Jeanes Hospital; died June 1, aged 54, of coronary atherosclerosis.

Brockman, James Manning ⊕ Memphis, Tenn.; born in Chattanooga Aug. 9, 1903; University of Tennessee College of Medicine, Memphis, 1928; assistant professor of obstetrics and gynecology at his alma mater; specialist certified by the American Board of Obstetrics and Gynecology; member of the Southeastern Surgical Congress and the Endocrine Society; fellow of the American College of Surgeons and the International College of Surgeons; veteran of World War II; on the courtesy staff, Baptist Memorial Hospital; consultant in gynecology, St. Joseph Hospital and Le Bonheur Children's Hospital; attending gynecologist, John Gaston Hospital; attending gynecologist and chairman of the department of gynecology, Methodist Hospital, where he died June 17, aged 53, of ventricular fibrillation and coronary arteriosclerosis.

Webb, Walter Duval ⊕ Colonel, U. S. Army, retired, St. Augustine, Fla.; born in Mankato, Minn., June 15, 1872; Columbia University College of Physicians and Surgeons, New York City, 1895; veteran of the Spanish-American War and World War I; entered the medical corps of the U. S. Army in 1900; retired with the rank of major in January, 190 returned to active duty from February, 1917, t September, 1918; retired with the rank of colone under the Act of June 21, 1930; returned to activ duty in December, 1940, to August, 1946; durin World War II head of the medical department fo Selective Service in the State of Florida; life member of the American College of Surgeons; formerl on the faculty of Georgetown University School o Medicine in Washington, D. C.; died June 12, age 84, of coronary heart disease.

Parsons, Frederick William, New York City; bor in Buffalo Nov. 13, 1875; University of Buffal School of Medicine, 1901; an associate member o the American Medical Association; specialist cert fied by the American Board of Psychiatry an Neurology; fellow of the American Psychiatric Association; member of the Association for Researc in Nervous and Mental Disease; for many yea state commissioner of mental hygiene; entered th state hospital service in 1902 as a member of th staff of the Hudson River State Hospital in Poughkeepsie, where he remained until 1919, when h was appointed superintendent of the Buffalo Stat Hospital; veteran of World War I; died in th French Hospital July 5, aged 81, of arterioscleroti heart disease and cerebral thrombosis.

Burch, Frank Earl ⊕ Two Harbors, Minn.; born i Menominee, Wis., March 27, 1876; University o Minnesota College of Medicine and Surgery, Minneapolis, 1897; professor emeritus of ophthalmolog and otolaryngology at the University of Minnesota Medical School; specialist certified by th American Board of Ophthalmology; member an past-president of the American Academy of Ophthalmology and Otolaryngology; member of th American Ophthalmological Society; fellow of th American College of Surgeons; veteran of Worl War I; served on the staff of the Charles T. Miller Hospital in St. Paul; died in Duluth, Minn., July 1, aged 81, of arteriosclerotic heart disease.

Willson, Prentiss ⊕ Venice, Fla.; born in Fredonia, N. Y., Aug. 2, 1882; Georgetown University School of Medicine, Washington, D. C., 1905; formerly

---

⊕ Indicates Member of the American Medical Association.

practiced in Washington, D. C., where he was on the faculty of his alma mater, and on the staffs of the Georgetown University Hospital and the Columbia Hospital for Women and Lying In Asylum; veteran of World War I; past-president of the Medical Society of the District of Columbia; Georgetown Clinical Society, the Clinico-Pathological Society, and the Washington Gynecological Society; specialist certified by the American Board of Obstetrics and Gynecology; died June 25, aged 74, of cerebral hemorrhage.

Wolfe, Stanley George ⊕ Shreveport, La.; born in Shreveport Nov. 6, 1905; University of Texas School of Medicine, Galveston, 1932; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; fellow of the American College of Physicians; past-president of the Louisiana State Society; formerly vice-president of the Tri-State Medical Society; served as chief of pediatrics service at Confederate Memorial Medical Center, and on the staffs of the Highland Hospital, North Louisiana Sanitarium, and T. E. Schumpert Memorial Sanitarium; died in Philadelphia June 22, aged 51.

Thornton, Lawson ⊕ Atlanta, Ga.; Johns Hopkins University School of Medicine, Baltimore, 1910; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; veteran of World War I; on the staffs of Piedmont Hospital, St. Joseph's Infirmary, and Grady Hospital; died June 26, aged 73, of cerebral hemorrhage.

Van Leuven, Buell Hitchcock, Empire, Mich.; Detroit College of Medicine and Surgery, 1915; fellow of the American College of Physicians; at one time mayor of Petoskey, Mich., director of the Grand Traverse County (Mich.) Health Department, and consultant for the state department of vocational rehabilitation; formerly member of the staff of James Decker Munson Hospital, Traverse City, where he died June 18, aged 69, of myocardial infarction and arteriosclerotic heart disease.

Arnovitz, Emanuel Morris ⊕ Granite City, Ill.; St. Louis University School of Medicine, 1924; veteran of World War I; on the staffs of the Missouri Baptist Hospital, St. Louis, and St. Elizabeth Hospital, where he died July 8, aged 60, of uremia, nephrosclerosis and osteomyelitis of the vertebrae.

Atkinson, Newell Wrigley, Alice, Texas; University of Texas School of Medicine, Galveston, 1898; died July 5, aged 81.

Bacon, Otis Guy ⊕ Frederick, Okla.; University of Louisville (Ky.) Medical Department, 1907; veteran of World War I; died July 6, aged 76, of intestinal obstruction.

Baskett, Roy Frederick ⊕ Texarkana, Ark.; Washington University School of Medicine, St. Louis, 1924; veteran of World War I; on the staff of St. Michael's Hospital; died May 19, aged 58, of cerebral hemorrhage.

Brady, Charles Joseph ⊕ Lake Geneva, Wis.; University of Wisconsin Medical School, Madison, 1934; veteran of World War II; died in the Lakeland Hospital, Elkhorn, July 11, aged 53.

Brady, Thomas S. ⊕ Bayonne, N. J.; Fordham University School of Medicine, New York City, 1919; served as Hudson County assistant medical examiner; on the staff of the Bayonne Hospital; died July 6, aged 59.

Branon, Anthony William ⊕ Old Saybrook, Conn.; Jefferson Medical College of Philadelphia, 1913; fellow of the American College of Surgeons; veteran of World War I; an honorary member of the staff, Hartford (Conn.) Hospital; member of the Chamber of Commerce and the Rotary Club; died July 3, aged 69, of coronary disease and arteriosclerosis.

Brown, Harry Abed, Lehman, Pa.; Medico-Chirurgical College of Philadelphia, 1903; an associate member of the American Medical Association; served as deputy coroner of Lehman and Lake townships; on the staff of the Nesbitt Memorial Hospital; for many years treasurer of the school board; died June 12, aged 79, of cancer of head of the pancreas.

Brown, William Riley ⊕ Ogden, Utah; University of Illinois College of Medicine, Chicago, 1913; fellow of the American College of Surgeons; veteran of World War I; associated with Dee and St. Benedict's hospitals; died June 7, aged 68, of myocardial infarction and arteriosclerotic heart disease.

Brownell, Clifford White, Sussex, N. J.; Long Island College Hospital, Brooklyn, 1910; served as president of the Alexander Linn Hospital; died in the Orange (N. J.) Memorial Hospital June 15, aged 71.

Bundy, Erwin Stillman, Southington, Conn.; University of Vermont College of Medicine, Burlington, 1913; school physician for many years; died in the Bradley Memorial Hospital July 3, aged 68.

Burnside, Raymond Alexander ⊕ Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1923; on the staffs of the Mercy and Lutheran hospitals; died June 23, aged 65.

Calhoun, Hazen Albert Jr. ⊕ Higganum, Conn.; Tufts College Medical School, Boston, 1934; veteran of World War II; died in Watertown, Mass., June 7, aged 50, of coronary thrombosis.

Caraker, Charles Tobias Jr., Perry, Fla.; Atlanta Medical College, 1914; veteran of World War I; died June 13, aged 67.

Chadwick, Suzanne ⊕ Bronxville, N. Y.; Cornell University Medical College, New York City, 1948; certified by the National Board of Medical Examiners; on the staffs of the Lawrence Hospital in Bronxville and the White Plains (N. Y.) Hospital, where she died June 27, aged 34, of Laennec's cirrhosis.

Chesbrough, Phrania, Atlanta, Ga.; Ensworth Medical College, St. Joseph, Mo., 1899; for many years practiced in Willoughby, Ohio; died July 6, aged 86, of septicemia and arteriosclerosis.

Chesnutt, James H. ⊕ Hot Springs National Park, Ark.; Johns Hopkins University School of Medicine, Baltimore, 1907; past-president of the Garland County Medical Society; past-chairman of St. Joseph's Hospital staff on which he served for many years; died June 8, aged 77, of acute coronary occlusion.

Chronik, Joseph B., Dunedin, Fla.; Temple University School of Medicine, Philadelphia, 1921; for many years practiced in Columbus, Ohio; died near Chillicothe, Ohio, June 19, aged 62, in an automobile accident.

Church, Lee O., Pelahatchie, Miss.; Illinois Medical College, Chicago, 1908; veteran of the Spanish-American War; died in the Veterans Administration Hospital, Jackson, June 26, aged 80.

Ciampolini, Ettore, New Haven, Conn.; Boston University School of Medicine, 1916; died in the Littleton (N. H.) Hospital June 27, aged 80.

Clark, Earl Finley ⊕ Belle Plaine, Kan.; University of Kansas School of Medicine, Kansas City, 1910; past-president of the Sumner County Medical Society; a veteran of World War I; died in the Veterans Administration Hospital, Wichita, June 2, aged 77.

Cobb, Elliott Cunningham, Davenport, Iowa; University of Nebraska College of Medicine, Omaha, 1913; fellow of the American College of Surgeons; past-president of the Woodbury County Medical Society; veteran of World War I; died June 10, aged 69, of cancer of the stomach.

Cooke, Grady Carlyle, Morehead City, N. C.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1919; specialist certified by the American Board of Surgery; member of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; formerly practiced in Winston-Salem; on the staff of the Morehead City Hospital, where he died July 7, aged 63.

Cook, Norman Lyle ⊕ Cape Girardeau, Mo.; Jefferson Medical College of Philadelphia, 1933; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthesiologists; veteran of World War II; on the staffs of St. Francis and South East Missouri hospitals; died June 26, aged 50.

Corrigan, John Francis ⊕ Cleveland; Western Reserve University School of Medicine, Cleveland, 1913; fellow of the American College of Surgeons; for many years on the staff of St. Alexis Hospital, where he died June 24, aged 68, of myocardial infarction.

Cox, Ernest Harper ⊕ Cleveland; Western Reserve University Medical Department, Cleveland, 1905; fellow of the American College of Surgeons; on the staff of the Women's Hospital; died June 9, aged 78.

Coyne, Douglas Ruthven ⊕ Detroit; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1924; member of the American Academy of General Practice; died in the Ford Hospital June 1, aged 58.

Cramer, Ray D., Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1936; died in the Germantown Hospital June 16, aged 45.

Crawford, Clyde Houston, Bartlett, Texas; University of Nashville (Tenn.) Medical Department, 1905; served as city health officer; died in Carlsbad, N. M., June 21, aged 77, of arteriosclerotic heart disease.

Daniel, James Wallace ⊕ Claxton, Ga.; Atlanta Medical College, 1894; served as state senator and as chairman of the county board of health; died June 25, aged 85, of coronary thrombosis.

Daniels, Frank Marion Jr. ⊕ Greenville, S. C.; Medical College of Georgia, Augusta, 1932; member of the American Academy of General Practice; associated with the St. Francis Hospital and the Greenville General Hospital, where he died June 27, aged 49, of heart failure.

Olson, William Paul, Los Angeles; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; died April 16, aged 70, of cerebral hemorrhage.

Packard, Lawrence Ralph, Whitehall, Mont.; Northwestern University Medical School, Chicago, 1900; an associate member of the American Medical Association; served as mayor; died July 1, aged 80, of diabetes mellitus and myocarditis.

Perry, Robert Edward ⊕ Greensboro, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1921; died in the Wesley Long Hospital June 23, aged 61, of myocardial insufficiency.

Phaneuf, Josephat Stanislas Policarp ⊕ Brockton, Mass.; College of Physicians and Surgeons, Boston, 1913; died June 30, aged 69, of cerebral embolism and auricular fibrillation.

Pinson, Jacob David ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1924; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; on the staff of the Albert Einstein Medical Center, Northern Division; died in Ventnor, N. J., July 4, aged 59, of acute coronary occlusion.

Porter, George B., Lathrop, Mo.; University Medical College of Kansas City, Mo., 1900, died in the Memorial Hospital, Corpus Christi, Texas, May 11, aged 80, of adenocarcinoma of the lung.

Proctor, Benona Jones, Los Angeles; Rush Medical College, Chicago, 1926; died in Newhall, Calif., June 28, aged 59, of coronary occlusion.

Rainsford, Laurence Frederick, White Plains, N. Y.; Columbia University College of Physicians and Surgeons, New York City, 1909; died in the White Plains Hospital July 4, aged 76, of myocardial infarction and coronary sclerosis.

Reitzel, Claude Everett, High Point, N. C.; Atlanta College of Physicians and Surgeons, 1902; member of the Medical Society of the State of North Carolina; on the staff of the High Point Memorial Hospital, where he died June 19, aged 77, of myocardial infarction and arteriosclerosis.

Rhudy, George Garland ⊕ Roanoke, Va.; Medical College of Virginia, Richmond, 1915; died near Strasburg, Colo., June 20, aged 68.

Ross, Horace B. ⊕ Del Rio, Texas, Atlanta Medical College, 1895; served as city and county health officer; formerly associated with the U. S. Public Health Service; on the staff of the Del Rio Hospital; died June 10, aged 88, of arteriosclerosis.

Ross, Howard Albertus, Longview, Texas; University of Texas School of Medicine, Galveston, 1909; served on the Carthage and Longview school boards; died June 26, aged 77, of hypertensive heart disease.

Roth, Irving R. ⊕ New York City; Long Island College Hospital, Brooklyn, 1917; specialist certified by the American Board of Internal Medicine; member of the American College of Gastroenterology; formerly on the faculty of the New York Polyclinic Medical School and Hospital; consulting cardiologist at the Mount Sinai Hospital and the U. S. Public Health Service; died June 25, aged 71, of cerebral vascular accident.

Rothkugel, Paul R., Philadelphia; Medico-Chirurgical College of Philadelphia, 1908; long time district medical supervisor with the board of education; associated with Jewish Hospital. now the Northern Division of Einstein Medical Center; died in the Norristown (Pa.) State Hospital June 20, aged 70, of arteriosclerosis.

Rouse, Benjamin H., Le Roy, Kan.; Loyola University School of Medicine, Chicago, 1919; on the staff of the Coffey County Hospital, Burlington, where he died June 25, aged 70, of coronary disease.

Salvin, Monte ⊕ Beverly Hills, Calif.; Jefferson Medical College of Philadelphia, 1928; died June 18, aged 54, of nephritis.

Schwabland, William Tecumseh, Los Angeles; Sioux City (Iowa) College of Medicine, 1901; died June 20, aged 80.

Shack, David N., Newark, N. J.; Baltimore Medical College, 1910; served on the New Jersey Compensation Board and the city board of health; on the courtesy staff of the Beth Israel Hospital; died July 5, aged 71, of cerebral hemorrhage.

Shapiro, Robert, New York City; University and Bellevue Hospital Medical College, New York City, 1915; member of the Medical Society of the State of New York; died June 19, aged 64, of coronary disease.

Shea, William Edward, San Francisco; George Washington University School of Medicine, Washington, D. C., 1905; veteran of World War I and received from Gen. John J. Pershing a special medal for his services; on the staff of St. Mary's Hospital; died June 25, aged 76, of coronary occlusion and arteriosclerosis.

Sisson, Sanford S., Jacksonville, Fla.; Kentucky University Medical Department, Louisville, 1902; died June 19, aged 79, of pulmonary congestion and cardiac failure.

Strickler, Mary E. Ranson, Burlingame, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1898; for many years practiced in Sleepy Eye, Minn.; died June 21, aged 84, of heart failure.

Smith, E. Florence Stir, Newark, Ohio; Laura Memorial Woman's Medical College, Cincinnati, 1901; Eclectic Medical Institute, Cincinnati, 1904; died June 27, aged 86.

Stennis, James H. ⊕ Mathiston, Miss.; Memphis (Tenn.) Hospital Medical College, 1898; died June 26, aged 84, of cerebral hemorrhage.

Stewart, Vida Odessa, Anguilla, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; died June 27, aged 73.

FOREIGN LETTERS

BRAZIL

Fatty Infiltration of the Liver After Portocaval Anastomosis.—Portocaval anastomosis is performed in the treatment of patients with hepatic cirrhosis, but it may cause some alterations in the physiology of the liver. Some of these alterations are not yet well understood, as, for instance, the fatty infiltration of the organ and its incapacity for parenchymal regeneration. In order to diminish these undesirable effects arterialization of the liver at the time of portocaval anastomosis has been proposed. Goffi and Gonçalves (*Rev. paulista med.* 50:317, 1957) reported a study of 30 dogs divided into three groups: the 13 animals of the first group were subjected to simple portocaval anastomosis; the 7 of the second group to portocaval anastomosis and aortoportal anastomosis; and the remaining 10 were used as controls. The degree of deposition of fat in the liver was studied in the three groups of dogs by histological examination and by the total amount of fatty acids in the liver. The authors concluded that terminolateral portocaval anastomosis permits a variable amount of fatty infiltration in the liver. The combining of aortoportal shunt and terminolateral portocaval anastomosis helps to diminish the frequency of the occurrence of the fatty infiltration of the liver.

Mast Cells.—The possible participation of mast cells in the pathogenesis of such disorders as thrombosis, atherosclerosis, and hemorrhage led Dr. Paulo S. Lacaz and co-workers (*Rev. brasil. cir.* 33:1, 1957) to study the functions attributed to these cells, namely, production of heparin, histamine, and hyaluronic acid. For this study they developed an original technique in which a mast cell increase was obtained in the liver of rats, an organ in which normally there are few if any such cells. This aim was achieved by subjecting lots of white rats to the inhalation of carbon tetrachloride during four months, five days in succession in each week. The liver of these rats (and in a second group of animals also the connective tissue) was examined at the end of each of the four months of poisoning. Immediately after the sacrifice of the animal the liver was taken out and studied by means of: (1) histochemical examinations; (2) extraction of heparin; (3) extraction of histamine; (4) bioassay of heparin (anticoagulant effect); and (5) bioassay of histamine.

The techniques adopted in the several phases of the investigation were also used for the study of the liver and lungs of oxen and dogs. The authors concluded that the hypertrophic hepatitis of rats due to carbon tetrachloride poisoning produced a marked increase in the amount of heparin and histamine derived from the presence of a large quantity of mast cells. This investigation confirms the suspected relation between mast cells and the production of heparin and histamine. On the other hand the production of hyaluronic acid by mast cells was not corroborated by this investigation.

Amebic Lesions of the Liver.—If amebic hepatic necrosis represents a clearly recognized clinical picture, the same is not true of acute and chronic amebic hepatitis. Da Silva and Torres (*O Hospital* 51:663, 1957) reported an analysis of 725 autopsy protocols and found only one case of confirmed amebic abscess of the liver. Searching for other amebic lesions of the liver, they studied the records of 82 patients suffering from amebiasis, but no reference was found of any clinical picture, past or present, that suggested the possibility of some form of amebic hepatitis. To have a uniform criterion for the diagnosis of amebiasis, the authors decided to include in their study only the cases (40) whose diagnosis was established by the presence of cysts of Entamoeba histolytica in the stools. For all these 40 cases the records included the results of several liver function tests, a complete blood count, a sedimentation rate, a roentgenogram of the chest, a complement-fixation test for amebiasis, and a needle biopsy of the liver.

In 7 of these 40 cases the disease had begun two years before the patient's hospital admission, and on admission the patient was having an acute exacerbation. In the rest of the patients the disease was chronic, having begun at least five years earlier. The ages of the patients varied from 21 to 54 years. In only 18 of these patients was some other hepatic disease, such as schistosomiasis, viral hepatitis, protein deficiency, syphilis, or malaria, not found. No specific changes directly related to amebiasis could be demonstrated. The mild lesions observed corresponding to the designation of acute amebic hepatitis were related either to the absorption of bacterial products through the damaged intestine or to some nutritional deficiency coexistent with parasitic infection or caused by it. A histological picture of a true amebic hepatitis could not be found, even in cases associated with some degree of hepatic enlargement and tenderness.

The items in these letters are contributed by regular correspondents in the various foreign countries.

INDIA

Threatened Abortion.—N. Kishore and co-workers (*J. Obst. & Gynec. India* 7:4 [June] 1957) stated that there should be little or no cornification of cells in the vaginal smears of pregnant women who are progressing normally and that most of these cells should be basophilic. The vaginal smear can be used to detect changes in the cytology in patients with threatened abortion, to determine the minimum degree of cornification that would cause inevitable abortion, to learn whether the degree of cornification can in any way be correlated with the clinical findings and the obstetric history of such patients, to predict the ultimate outcome on the basis of these changes, to assess the accuracy of such predictions, and to suggest a line of treatment to be adopted on the basis of these changes. One hundred patients with threatened abortion were thus studied. The results were correlated with the obstetric history. It was found that the prognosis was best in the group who had smears resembling those of normal pregnancy. The prognosis in the group with up to 30% cornified cells was fair. Those with 31 to 60% cornified cells had a poor prognosis, and it was worst in those with over 60% cornified cells. The obstetric history was of prognostic importance in those in whom the smears resembled those of normal pregnancy or had up to 30% cornified cells. The prognosis was good if these patients had a good obstetric history or were primigravida. The history had no bearing in those with smears showing more than 30% cornified cells. In these patients cytological interpretations were more accurate. The presence of 30% cornified cells should be considered as the borderline below which a good prognosis may be given. Patients with 31 to 60% cornification may be benefited by hormonal therapy. This method can be used to institute early and accurate hormonal therapy and to follow the progress of the case. Predictions were correct in 87.8% of cases.

Renal Biopsies.—L. R. Sarin and co-workers (*J. Indian M. A.* 29:1 [July 1] 1957) stated that needle biopsy has been found useful in the diagnosis of diseases of the kidney, especially when routine laboratory investigations fail to show involvement of the kidney in such conditions as diabetic nephropathy, systemic lupus erythematosus, and periarteritis nodosa. The authors determined the prothrombin time, bleeding time, and clotting time before performing the biopsy. Biopsies were done only on the right kidney and with the patient in two positions, prone and sitting. Of 35 biopsies on 34 patients, tissue suitable for histopathological examination was obtained in 20. The tissue from a normal kidney is pink with red granules. In patients with the nephrotic syndrome, the tissue is nearly white and translucent with no red granules. None of the patients had any serious reactions after the biopsy. All had local backache and transient microscopic hematuria. Of 12 conditions diagnosed clinically as nephrotic syndrome, 5 were found to be amyloidosis. The rest were found to be various stages of glomerulonephritis. In two young patients suffering from diabetes, diffuse intercapillary glomerulosclerosis was diagnosed. Although renal biopsy is a valuable adjunct in the diagnosis of renal disease, its scope is limited, as a satisfactory piece of kidney tissue is not obtained in every case.

Cardiac Disease and Pregnancy.—K. M. Masani (*J. Obst. & Gynec. India* 7:4 [June] 1957) reviewed 47 cases of cardiac disease associated with pregnancy collected from a series of 22,833 full-term confinements. This gives an incidence of cardiac disease of 0.2%. In 41 patients the heart disease was of rheumatic origin, and in 6 it was congenital. In the entire series mitral stenosis was the commonest organic lesion, being present in 29 patients; 3 had mitral insufficiency; 8 had mitral stenosis with insufficiency; and 2 had mitral stenosis with aortic insufficiency. Mitral valve lesions alone or in combination with other lesions accounted for all but one case of acquired valvular disease. Of the patients with congenital heart disease, one had an interventricular septal defect, one had an interauricular septal defect, two had both, and in one the type of lesion could not be defined. Although the findings in this series showed that the incidence of severe decompensation increases with age and parity, young primiparas with severe decompensation were seen.

Ten patients with cardiac disease were below the age of 20 years, 5 being primiparas and 5 secundiparas. One of these primiparas was seen for the first time during labor and died, without being delivered, from pulmonary edema. The cardiac lesion of only one primipara was of class I (according to the classification of the American Heart Association, 1945). In the entire series, 18 were of class I, 22 of class II, 3 of class III, and 4 of class IV. Patients of class I had no symptoms and were given a diagnosis by routine examination. In the patients of class II dyspnea on exertion was the chief symptom. Those of classes III and IV had dyspnea, orthopnea, cough, and edema. The management during pregnancy was by rest, salt restriction, ammonium chloride mixture if edema was present, and mercurial diuretics or acetazolamide if the urinary output was diminished. Anemia was commonly associated and was treated by iron, liver, vitamin B_{12}, and folic acid. All but two patients who required forceps delivered spontaneously. There were three deaths. One died, without being delivered, of pulmonary edema; one from cardiac failure eight hours after delivery; and one five days after delivery.

Health Program on "War Footing."—Two hundred delegates attending the Rajkot and Ahmedabad division public health and rural sanitation seminar recommended to the government of Bombay that the health program in the state be put on a "war footing." The seminar recommended the delegation of powers to medical officers to buy drugs, medicaments, and insecticides in times of emergencies. It also suggested that there should be day-to-day coordination of work between the health and developmental departments in rural areas so that the medical department could continue its work even after its period of the developmental program ended in a particular area. The seminar recommended that a health committee for every village in a development block be set up and made responsible for submission of a report to the primary health center on the occurrence of any communicable disease in the village. It also suggested that the department of health give adequate training to workers at the village level in first aid. The seminar also agreed on the suggestion to organize cleanliness drives in villages for a week every year and to hold intervillage competitions in rural sanitation.

Aviation Medicine.—The government has set up a school of aviation medicine at Bangalore. The school will concurrently run separate courses for Air Force medical officers, pilots, navigators, other personnel of the general duties branch, and airmen of the medical branch. Indian Air Force medical officers had hitherto to be sent abroad for this type of training.

NEW ZEALAND

Controlled Hypotension in Neurosurgery.—About 20% of the patients in whom controlled hypotension was induced with hexamethonium bromide and augmented first by posture and later by applying negative pressure to the legs failed to respond. It appeared that in these patients, after the maximum effect of hexamethonium bromide had been obtained, at least some of the blood vessels were contracted. One possible explanation was that this might be due to circulating epinephrine or arterenol acting peripherally on the vessel walls. With this hypothesis in mind, R. L. Coulter (*Anaesthesia* 12:74, 1957) reported the results of using adrenergic blocking agents. After preliminary trials with chlorpromazine, Dibenzyline (N-phenoxyisopropyl-N-benzyl-β-chloroethylamine hydrochloride) was chosen. Dibenzyline is several times more powerful than its predecessor Dibenamine, and much less toxic. Dibenzyline dissolved in propylene glycol and alcohol and acidified with hydrochloric acid was given to 26 neurosurgical patients resistant to hexamethonium; there was a resultant drop in blood pressure in 25 of them. The smallest effective total amount was 25 mg., but most of the patients had 50 to 100 mg. In only four of these patients was the pulse rate, after hexamethonium therapy, under 100 per minute. In many it was 140 to 160. Dibenzyline had no apparent effect on the pulse rate. Coulter concluded that the failure of large doses of hexamethonium to produce a useful degree of postural hypotension in a small proportion of patients is probably due to the presence of circulating epinephrine and perhaps arterenol, causing a direct vasoconstriction and usually a tachycardia. The vasoconstriction but not the tachycardia can usually be abolished by the use of Dibenzyline.

Adrenalectomy Follow-ups.—The population of New Zealand is widely scattered in small towns far from the main city hospitals. According to Woodruff and co-workers (*Australian & New Zealand J. Surg.* 26:297, 1957) total adrenalectomy for the palliative treatment of disseminated cancer of the breast would not be feasible for patients living in rural areas owing to difficulties in assessing maintenance. One of their patients, however, is taking a daily minimum maintenance dose of 0.3 mg. of fludrocortisone and 40 mg. of cortisone. Her clinical state is maintained from biweekly estimations of urinary sodium and potassium and of blood sugar levels. The patient has been instructed to collect and measure her urinary output on the relevant days and to mail a small sample labeled with the total volume to the Otago Medical School at Dunedin. Blood specimens are obtained by a country doctor and also sent to Dunedin. The results are referred to the country doctor. The procedure has been most satisfactory for both the patient and her medical advisors.

High-speed Dental Drill.—Selling dentistry to the New Zealand public, with quickly-decaying teeth, promises inestimable benefits. The dental profession here has welcomed the new high-speed drill, which is painless. The secret of its success is the speed with which it revolves—about 250,000 rpm compared with present speeds of 8,000 to 10,000 rpm. Dental researchers had known for years that higher speeds would cut vibrations, the cause of much pain. A turbine driven by compressed air has been found to give the desired speed, and a hand piece has been designed which is no larger than the present ones. Heat, another cause of the patient's discomfort, has been eliminated by using a fine spray of cold water.

Dental Prophylaxis.—Professor F. Wilkinson, Dean of the University of London Postgraduate Dental School and chairman of the Education Committee of the General Dental Council of Great Britain, recently paid a visit to the University of Otago Dental School. The purpose of Professor Wilkinson's visit was to look into the training of dental nurses in New Zealand. A similar training scheme is now to be established in Great Britain. Dental attention must be carried out continuously to be effective, Professor Wilkinson said, and he advocated the continuation of state responsibility up to the age of 21, when a person could be expected to seek treatment himself. He suggested that dental nursing should attract more young women, who are well suited for dealing with children, as it is a job which can be continued part time after marriage.

Amendment of Law on Insanity.—Power for a magistrate to order the confinement of a person who is not sane enough to plead when charged with a summary or indictable offense is given in the Mental Health Amendment Bill that was introduced to the House of Representatives recently. At present there is no provision for the case where a person is found by the magistrate's court at the preliminary hearing to be unfit to plead, or for the case of a summary charge. Such confinement—the pleasure of the Minister of Justice—can be ordered only if a person is found by a jury to be insane so that he cannot plead. The bill also allows boards incorporated under the religious, charitable, and educational trusts to operate "short-stay" homes for mentally retarded children. At present, these homes can be operated only by incorporated societies. The period during which a child under the age of 18 years can stay in these homes is extended from a maximum of two months at any time to a period approved by the director of the mental hygiene division of the Health Department. A proviso is that satisfactory facilities for training must not be available in the locality where the child usually lives but are available either in or near the home.

UNITED KINGDOM

Mental Illness in Scotland.—The annual report of the Scottish Board of Control reveals that in 1956 the number of admissions to mental hospitals was 10,147, compared with 9,168 in the previous year. Some patients were admitted more than once, and, taking this into consideration, the number of patients actually admitted was 9,200. The number of voluntary admissions rose to a record figure of 73% of the total admissions. The shortage of accommodations for mental defectives is still acute, in spite of the increased expenditure on mental health by the National Health Service. The number of mental patients cared for in private dwellings has increased to 341. In 1956 there were 8 suicides and 55 accidental deaths in mental hospitals. The use of tranquilizers has temporarily improved many psychotic patients, some of whom were returned home for short periods, but many of them broke down again and returned to the hospital. More patients are being treated by the "open" method, without locked doors. Week-end leave is often permitted, and even suitable outside employment is allowed. Occupational therapy is being used more, and greater use has been made of group psychotherapy and discussions, recreation (games, music, and television), and instruction in useful crafts and domestic activities.

Drug Addiction.—Great Britain remains comparatively free of addiction to drugs (chiefly narcotics) controlled by the Dangerous Drugs Acts. The number of known addicts in 1956 in the United Kingdom was 333, according to the British government's report to the United Nations. Among the addicts were 77 doctors, 2 dentists, and 20 nurses, or 30% of the total. Those addicted to morphine numbered 176, to meperidine hydrochloride 64, to heroin 53, to methadone 20, to phenadoxone 8, to cocaine 6, and to levorphanol tartrate 4. Apart from members of the medical and allied professions, who have access to narcotics, no occupational group appears to be unusually associated with addiction, although a small but appreciable number of dance-band musicians are known addicts. In 1956, 42 cases of addiction were reported; 3 of these were in recidivists. Opium smoking is rare and is practiced mostly by Asiatics in seaports. Most of the traffic in marihuana occurs in London. There were 103 convictions for dealing in or possessing the drug, 60% of them in London, the offenders being mostly of West African or West Indian origin. Since addiction is not a serious problem here, there are no state institutions for investigating the problem or for treatment, which is carried out in public hospitals and private nursing homes. In the home office an official record is kept of all known drug addicts. In 1956, 54.2 kg. of opium and 114.1 kg. of marihuana were seized. There were 157 prosecutions and 151 convictions for violation of the narcotic laws. Nearly all those convicted for offenses involving manufactured drugs were of European origin. Most addicts obtain drugs by forged prescriptions or by getting supplies from more than one physician.

Health Service Reform Plan.—A plan for a reformed Health Service on the basis of personal insurance aided by state subsidy, which could mean a net saving to the exchequer of 392 million dollars a year, is being sponsored by the Fellowship for Freedom in Medicine. It contains features adapted from the Australian system. The main objectives are to check the deterioration of the traditional high standards of medicine and to curb the ever-mounting cost to the taxpayer. The fellowship, which consists mainly of physicians, was founded by the late Lord Horder. A schedule of standard benefits would be agreed on between the Ministry of Health, the insurance companies, and the medical profession. The insurer would pay 60% of the benefit and the exchequer 40%. The patient would pay the fees not covered by the terms of insurance. On the principle of the motorist's "no claim" bonus, it is suggested that, as an inducement to patients not to make unnecessary demands, an insurance company might offer certain extra benefits to patients whose claims in a year did not exceed a certain sum.

The *British Medical Journal*, Aug. 3, notes that, according to the Fellowship for Freedom in Medicine, the major faults of the National Health Service are (1) the virtual abandonment of the insurance principle, (2) the policy of focusing the Service on the hospital rather than on the family physician, and (3) the widespread delusion among the public that their insurance payments cover the costs of the Service. The fellowship believes that the Health Service in its present form has a harmful effect on the practice of medicine and advocates a state-subsidized compulsory insurance of physicians' and hospital fees by those in a position to pay for it and a free Health Service for all others. The effect of the proposals is to give the insured person and his dependents about 90% coverage against the costs of general practitioner and hospital treatment. The motive behind the scheme is the laudable one of running a Service that places at least some direct responsibility on the patient for his health. This aim is in line with the following recommendation made by the World Medical Association in 1952: "Any Social Security Scheme should contain elements that encourage self reliance and a sense of personal responsibility; and . . . any Social Security Scheme should stress the obligation of the individual to make at least part of his contribution directly to the functioning and costs of the Scheme."

Rheumatoid Arthritis.—The joint committee of the Medical Research Council and the Nuffield Foundation have reported the results of clinical trials designed to compare the effectiveness of cortisone with that of prednisone in the treatment of rheumatoid arthritis. Sixty-eight patients who had been treated with cortisone for a year or more were divided into two groups, matched as far as possible for age, sex, duration of disease, and duration of cortisone therapy. One of each pair selected at random continued to receive cortisone. The other was changed to prednisone therapy, the dosage of which was commenced at one-third of the amount of cortisone the patient had been taking and subsequently adjusted so that the patient received the maximum benefit without side-effects. Both groups were followed up for a year. Clinical assessment was based on a judgment of the activity of the disease and an evaluation of the patient's general functional capacity. The strength of grip in each hand was measured, and laboratory tests were made with respect to the sedimentation rate and hemoglobin level.

Throughout the trial the patients remaining on cortisone therapy showed, on the average, no material change for better or worse, compared with their state in the previous year, but those getting prednisone showed improvement in strength of grip, sedimentation rate, hemoglobin level, and general functional capacity and decreased disease activity. After a year the disease was judged to be inactive in five of this group but in none of the patients getting cortisone. The patients on prednisone therapy received the greatest benefit in the first three months. Then, for the group as a whole, the benefit generally diminished thereafter, though it still remained, to a lesser degree, at the end of one year This partial loss of initial improvement may have been due to the general reduction that occurred in the dosage of prednisone during the course of the year. Although the dosage was adjusted to obtain the maximum benefit and minimum of side-effects the latter did occur, particularly "moon face," which was more prevalent in the prednisone-treated than in the cortisone-treated group. The more favorable results noted with prednisone might have been due, in part at least, to the use of a dosage that was relatively high in comparison with the cortisone dosage.

Salk Vaccine Gets into Britain.—Evidence is accumulating that large quantities of Salk poliomyelitis vaccine are arriving in Great Britain from the United States, although no import licenses have been issued by the Ministry of Health. Fears have been expressed by physicians that this "smuggling" is likely to become a matter of personal gain to unscrupulous people. At the moment this vaccine is being sought mostly by parents seeking protection for their children. British production to date has been sufficient to vaccinate only one million of the six million children aged between two and nine. Many physicians believe that the government should import enough vaccine to vaccinate children of all ages and any adults who so desire. The Ministry's restriction of the importation of the vaccine is based on the Therapeutic Substances Act, which requires licensing by the Ministry. Although no such licenses have been granted, the Ministry intimated that in certain circumstances the importation of small amounts would be authorized. These must be unsolicited gifts addressed to individuals. There must also be evidence that the vaccine is to be administered by a physician who accepts full responsibility. Most of the vaccine entering the country is arriving because of a liberal interpretation by both physicians and patients of the expression "unsolicited gifts." Some is being brought by returning travelers.

The *Daily Telegraph* stated that all physicians must know that Salk vaccine is being brought into Great Britain, but it is doubtful that anybody, including the Minister of Health and the Postmaster-General, knows how much. Since the disasters resulting from faulty manufacture of the vaccine earlier are not likely to be repeated, no physician using vaccine procured from the United States need have any anxieties about the results.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Paternity Tests: Admissibility in Proceeding for Nonsupport.—The defendant was indicted for a failure to provide for the support of his wife and two minor children. His motion for a blood test under the provisions of a 1954 law was reported without decision to the Supreme Judicial Court of Massachusetts.

The Commonwealth objected to the ordering of the blood test on the ground that the law was not applicable to proceedings for nonsupport. The superior court submitted two specific questions to the Supreme Judicial Court: (1) whether the provisions of chapter 278, section 12A, are applicable to proceedings brought for nonsupport of minor children; (2) whether expert testimony of blood tests, which show an exclusion, is admissible on the question of paternity in criminal proceedings brought for nonsupport of minor children born during wedlock. Chapter 278, section 12A, provides: "In any proceeding to determine the question of paternity, the court, on motion of the defendant, shall order the mother, her child and the defendant to submit to one or more blood grouping tests, to be made by a duly qualified physician or other duly qualified person, designated by the court, to determine whether or not the defendant can be excluded as being the father of the child. The results of such tests shall be admissible in evidence only in cases where definite exclusion of the defendant as such father has been established. If one of the parties refuses to comply with the order of the court relative to such tests, such fact shall be admissible in evidence in such proceeding unless the court, for good cause, otherwise orders."

In answer to the first question, the court held that, since the indictment for nonsupport is not a "proceeding to determine the question of paternity" the statute does not authorize an order that the mother and children therein named submit to a blood grouping test.

In answer to the second question, however, the Supreme Judicial Court held that expert testimony of blood grouping tests showing the definite exclusion of the defendant as the father of a child, the support of whom is the object of an indictment, is admissible if otherwise competent. Continuing, the court said that there is substantial authority to support the scientific reliability of blood grouping tests to prove biologically the impossibility of paternity. The court admitted that there is a presumption of legitimacy in the case of a child born in wedlock which can be overcome only by facts which prove beyond reasonable doubt that the husband could not have been the father. Proof of the impotency of the husband or no access to his wife, for example, are held to be sufficient. Since like certainty of proof appears obtainable through the definite exclusion of the husband's paternity by the tests here under consideration, the court concluded, it follows that evidence derived from blood grouping tests would warrant a finding beyond a reasonable doubt that the defendant is not the father of either child named in the indictment and would be admissible.

The case was therefore remanded to the trial court for further proceedings in accordance with such opinion.—*Commonwealth v. Stappen, 143 N.E. (2) 221 (Mass., 1957).*

Validity of Wife's Consent to Electroshock Treatment for Husband.—This was an action for damages against the insurer of a physician for injuries allegedly caused by the physician's malpractice. From a judgment for defendant, the plaintiff appealed to the United States court of appeals for the Fifth Circuit.

The insured physician, a psychiatrist, determined that the plaintiff needed some electroshock treatments. After having been informed of the possible hazards of such treatments, the plaintiff's wife consented to their administration to the plaintiff. The plaintiff, however, contends that administering the treatments without his consent deprived him of his freedom of contract and, therefore, of his liberty without due process of law. The evidence showed that the plaintiff needed neuropsychiatric treatment. It also showed, however, that his condition was such, in the judgment of his physician and his wife, as to make it unwise and unsafe to require him to undergo the strain of discussing and considering the possible hazards involved in electroshock treatments and of making a decision as to whether or not such treatments should be administered. The plaintiff's wife fully comprehended the situation and gave her consent to the treatments.

The case, said the court, must be governed by the principle that, before proceeding, a physician must acquaint a patient with the diagnosis and proposed treatment and obtain his consent, except that, when the circumstances require it, someone properly acting for the patient may give the consent. In such instance, the consent of the wife who fully understands the need and the hazards is a valid, legal consent. It was, therefore, not error, concluded the court of appeals, for the trial court to charge that there was a valid consent. Accordingly, the judgment for the defendant was affirmed. *Lester v. Aetna Casualty & Surety Company, 240 F. (2d) 676 (C. A. 5, 1957).*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Atrial Fibrillation Following Mitral Valvulotomy: A Study of Its Clinical Characteristics and Predisposing Factors. R. Heinz and H. Hultgren. A. M. A. Arch. Int. Med. 99:896-903 (June) 1957 [Chicago].

The most common postoperative complication in mitral valve surgery in patients with a normal sinus rhythm is the occurrence of atrial fibrillation. Sixty-seven of the 144 patients studied had atrial fibrillation at the time of surgery. Of the 77 patients who had a normal sinus rhythm prior to surgery, 36 (47%) developed atrial fibrillation postoperatively. Atrial fibrillation appeared within the first 7 postoperative days in 92% of the 36 patients. Fibrillation appeared most frequently on the second postoperative day, only 2 patients beginning to fibrillate on the day of surgery. In the patients who developed atrial fibrillation postoperatively, no significant relationship between the ventricular rate or the day of onset of fibrillation and the age of the patient was noted. The onset of atrial fibrillation resulted in an increase of the ventricular rate of 31 digitalized patients to a mean rate of 142, while 6 nondigitalized patients experienced a mean ventricular rate of 168. The patients with persistent sinus rhythm differ from the other 2 groups in being younger, but the difference between the postoperative fibrillation and chronic fibrillation groups is not sufficient to be of any statistical significance. Of those patients exhibiting postoperative atrial fibrillation, 28% gave a history of previous paroxysmal fibrillation, in contradistinction to those patients (5%) who maintained a normal sinus rhythm. A relationship of mild or moderate mitral insufficiency to persistent atrial fibrillation does exist, although no correlation is readily apparent between the size of the left atrium and the incidence of either persistent or postoperative fibrillation. Histological evidence of rheumatic carditis supports the tenet that positive auricular biopsies are more common in younger patients in whom the incidence of fixed or postoperative fibrillation is lower. Slowing of the ventricular rate after onset of atrial fibrillation was accomplished largely by the administration of additional digitalis glycosides. None of the patients having atrial fibrillation preoperatively reverted spontaneously to sinus rhythm postoperatively, while 10 patients who fibrillated postoperatively did have spontaneous return to sinus rhythm. Sinus rhythm restoration was successful in 16 patients (70%) who received an average of 2.5 Gm. of quinidine, which was not given until the 7th or 8th postoperative day in order to allow ample time for spontaneous conversion. Only 10 of the 36 patients who began to fibrillate postoperatively were not returned to sinus rhythm. Quinidine, given postoperatively to 18 patients who had atrial fibrillation preoperatively, resulted in sinus rhythm restoration in 7 (39%). The factors predisposing to fibrillation are the presence of associated mitral insufficiency, paroxysmal atrial fibrillation, and increasing age. There is no evidence to substantiate a decrease in intracellular potassium as the cause of atrial fibrillation.

Anemias of Hypophysial and Diencephalic Origin. J. Leprat. *Presse méd.* 65:892-895 (May 11) 1957 (In French) [Paris].

The hematological repercussions of diencephalic and hypophysial disorders have been the subject of intensive study in recent years. No convincing evidence has been found to show that anemia may result directly from any diencephalic condition, without the intervention of the pituitary body. Pituitary insufficiency, however, is responsible for the most frequent and severe anemias of all those that are attributable to an endocrine origin. The most significant factor in the production of the hypopituitary anemias seems to be the anterior lobe of the pituitary body. Thus it has been shown that the anemia produced by hypophysectomy in experimental animals does not appear when only the posterior and intermediate lobes are removed.

Anemia is almost constant in Sheehan's postpartum syndrome, and it is also common in patients with certain hypophysial tumors (chromophobe adenoma and craniopharyngioma) and in those with various other types of panhypopituitarism. Hematological studies show that the anemia accompanying all of these conditions is usually microcytic and either hypochromic or normochromic during the greater part of its course. The decline in the red blood cells is ap-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1948 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

parently due to hypoplasia of the marrow, found in most patients in association with fatty infiltration of the marrow. Gastric achylia is also a common finding in these patients. Hormone therapy is the only method by which the normal blood picture can be restored. A combination of thyroid extract with testosterone and cortisone given in small doses is effective in some cases, but in others recourse must be had to corticotropin, which seems to be the most active of the hypophysial hormones in this connection.

Experimental findings in hypophysectomized animals strongly suggest the existence of a specifically hematopoietic hypophysial principle, but whether this new hormone, if it exists, acts directly at the level of the medullary parenchyma or indirectly by means of more general metabolic changes is still a matter of speculation. Complex as this and the other problems connected with hypopituitary anemias are, their theoretical importance to hematologists and endocrinologists is so great that they should be given further study.

Asthmatic Wheezing: Compression of the Trachea and Major Bronchi as a Cause. E. Dekker and J. Groen. Lancet 1:1064-1068 (May 25) 1957 [London].

It is commonly assumed that the typical wheezing during the expiratory phase of the asthmatic attack is produced by a stenosis of the smaller bronchi and bronchioli. Opinions differ regarding the cause of this stenosis. Some attribute it to a spasm of the bronchial and bronchiolar musculature; others, to a partial obstruction by mucus, or edema and congestion of the bronchial mucosa, or both. The authors present evidence that it may be produced, at least partly, by a narrowing of the trachea and larger bronchi. They were able to confirm old observations that asthmatic patients and normal people can learn to wheeze at will by imitating the typical asthmatic expiration. This voluntarily produced wheezing is indistinguishable from the spontaneous wheezing during asthmatic attacks. X-ray studies during this voluntary wheezing reveal, both in normal subjects and in asthmatic patients, a considerable narrowing of the cervical and thoracic trachea and of the main bronchi. The same narrowing was found in x-ray pictures taken during expiration in patients with spontaneous asthmatic attacks.

In human lungs, obtained at autopsy, which were made to breathe under different pressure in a closed jar, an expiratory pressure of 1 cm. Hg or more produced a considerable stenosis by a prolapse of the membranaceous part of the trachea and main bronchi into the lumen. It is postulated that a similar passive compression of the larger air passages, caused by the high intrathoracic expiratory pressure which asthmatic patients produce as a result of their peculiar type of breathing, is an important factor in the production of the asthmatic bronchostenosis and of the expiratory wheezing which is so characteristic of this disease. These observations help indicate the mechanisms by which asthmatic attacks are brought about and by which they can disappear with breathing exercises.

A 36-Year Study of Diseases of the Chest on a University Campus (Concluded). J. A. Myers, R. E. Boynton and H. S. Diehl. Journal-Lancet 77:171-181 (May) 1957 [Minneapolis].

In a previous paper, an abstract of which appeared in THE JOURNAL (164:1154 [July 6] 1957), the authors reported on their experience with diseases of the chest studied at the clinic for the diagnosis and treatment of tuberculosis and other diseases of the chest at the University of Minnesota student health service between 1920 and 1956. They had emphasized the magnitude of the problem of clinical tuberculosis on the campus which led to adoption of successful methods for its control. The incidence of contagious tuberculosis increases as people grow older. Thus a tuberculosis control program among faculty and personnel members is exceedingly important. Tuberculous pleurisy with effusion was seen in 119 persons. Extrathoracic tuberculosis involving bones, joints, kidneys, lymph nodes, and meninges has been observed in 61 persons.

There may be students or faculty members on a campus with clinical and even contagious tuberculosis who feel and appear well and are not discovered unless a detailed search is made for them. The best search consists of testing all with tuberculin and subjecting reactors to a complete examination, including roentgenograms of the chest. Every student who reacts characteristically to the tuberculin test, either on entrance or while in school, should be apprised of the fact that multiple lesions exist in his body and that they contain living tubercle bacilli. He should be informed that these organisms may produce gross and clinical disease at any time during the remainder of his life. However, such disease can usually be detected before it has caused much destruction or spread to others and at a time when it can be treated successfully. Student health services can do much to help solve the serious problem of tuberculosis in national defense.

Primary Carcinoma of Liver: A Clinical Analysis of 107 Cases. Chung Hsüeh-Li and Ch'en Hao-Chu. Chinese M. J. 75:295-315 (April) 1957 (In English) [Peking].

Primary carcinoma of the liver is rare among Europeans and Americans but common among Africans and Orientals. In the 14 years from 1941 to 1954 the authors observed 217 patients with primary carcinoma of the liver among 61,487 admitted to 2 Shanghai hospitals. This report is concerned with 107 of these patients in whom the diagnosis was verified by histopathological examination of biopsy specimens of the liver. The ages of the patients ranged from 10 months to 66 years, but nearly 90% were between 31 and 60 years of age; there were 100 male and 7 female patients. The onset is insidious, symptoms being absent or very slight during the early stage. A growing mass in the abdomen, with pain, impairment of appetite, loss of weight, and fever are the usual symptoms during the late stage, when most of the patients reviewed here were first seen. Many appeared chronically ill and emaciated and a few were acutely ill, but in the others the general condition was fairly good. Enlargement of the liver was noted in all but 2 of the patients, in whom ascites made palpation difficult. The border of the enlarged liver usually extended 5 to 10 cm. below the right costal margin, causing bulging of the right upper quadrant of the abdomen. The liver was usually firm and tender, with an irregular surface. The spleen was palpable in 33 of the patients. Forty patients had jaundice. The laboratory findings and the main clinical features are discussed.

Although a tentative diagnosis of carcinoma of the liver may be made from an analysis of the history and physical findings, definite diagnosis depends upon the demonstration of cancer cells or neoplastic tissue. The authors investigated the merits of different diagnostic methods, and show that, apart from laparotomy, liver puncture and biopsy or smear examination for cancer cells with Wright's stain is the most reliable method, despite the risk of internal hemorrhage. The liver specimen obtained by puncture and biopsy may be examined either in sections or by the simple smear method. Search for cancer cells in the peritoneal and pleural fluids was not of great diagnostic value, and liver-function tests usually did not give much help in diagnosis. Resection was done in 1 of the patients, but urrence soon followed and the patient died 6 onths after operation. Two patients were treated with nitrogen mustard, but no definite therapeutic effect was observed. So far there is no satisfactory method of treatment. The authors believe that improvement in economic conditions, better nutrition, and proper treatment of gastrointestinal and hepatic disorders would aid the prophylaxis of carcinoma of the liver.

Leukaemia. R. B. Scott. Lancet 1:1053-1057 (May 25) 1957 [London].

The incidence of leukemia is increasing, and, while more precise diagnosis may explain some of this increase, the author believes that it does not explain all of it. The nature of the leukemic process is now generally held to be neoplastic; and, when "cancer" is defined in terms of dynamic cell behavior, there can be little quarrel with this view. It is undeniably a purposeless progressive uncoordinated cellular proliferation. The fundamental cause of leukemia is to be sought in the larger mystery of the cause of cancer. In commenting on external factors in the pathogenesis of leukemia the author mentions the higher incidence among survivors in atomic bomb explosions, in those who have received irradiation for ankylosing spondylitis or for thymic tumors, and among radiologists. A genetic factor seems to be indicated by the occasional report of several cases in one family. Leukemia has also been observed in almost every species of animal.

Acute leukemia is distinguished from the chronic form by the immaturity of the proliferating cells and the rapidity of its course. Myeloblastic, lymphoblastic, and monocytic varieties are recognized, but the distinction between the several primitive elements may be difficult, and refuge is often sought in the evasive qualification of "stem cell." There is, therefore, considerable variation in the reported incidence of the different types. More males than females fall victim to acute leukemia, an inequality due to the frequency of the lymphoblastic type in male children. The age-incidence of the 3 varieties shows striking differences. Myeloblastic leukemia is spread evenly throughout the whole span of life; lymphoblastic is predominantly a disease of children; and monocytic affects mainly the middle-aged. The different cytological varieties seldom present clear-cut clinical differences. The diagnosis of acute leukemia is established by examining the blood and bone marrow. When the changes in the peripheral blood are inconclusive, the diagnosis is established by bone-marrow puncture, which will reveal in almost every instance a replacement of the normal cells by myeloblasts, lymphoblasts, or primitive monocytes. The course of leukemia is so variable that figures of average duration have little meaning.

The fundamental aim of treatment is to control the neoplastic process and restore normal cellular behavior in the hemopoietic system, but symptomatic treatment must be considered. While blood transfusion has no place as a definitive means of treatment, it should be prescribed in quantities sufficient to maintain a hemoglobin level of 9 Gm. per 100 ml. while attempts are made to control the leukemic process. The "specific" agents which may exert partial or complete, although never more than temporary, control over the leukemic process are the steroid drugs and certain antimetabolites. In the present series, in 81 patients treated with blood transfusion and antibiotics alone the mean length of survival from the first symptom was 20.2 weeks, and in 63 who received in addition "specific" treatment, 21.7 weeks. These figures provide no cause for optimism, but the author has at present 6 patients in complete remission. It may be claimed that there are, at least, grounds for hope and encouragement in this recently acquired ability occasionally to halt for a while the formerly unrelenting malignant process known as acute leukemia.

Clinical Evaluation of 3 Anticoagulants in Thromboembolic Disease. J. M. E. Neilson and A. W. Mollison. Brit. M. J. 1:1214-1217 (May 25) 1957 [London].

Of 361 patients with thromboembolic disorders, 57 were treated with cyclocumarol (Cumopyran), 125 with ethyl biscoumacetate (Tromexan ethyl acetate), 79 with phenindione. Patients given ethyl bis- ıcetate or phenindione received 10,000 to 15,000 of heparin intravenously every 6 hours for the 4 hours of anticoagulant therapy. Because of its r effect on the prothrombin time, those given umarol received the same dosage of heparin 6 hours for 48 hours. Cyclocumarol, ethyl bis- acetate, and phenindione were given by mouth ided doses at 2 p. m. and 10 p. m. Two doses of . or 50 mg. of cyclocumarol on the first day were to be adequate for most patients. On the second doses of 12.5 or 25 mg. were most often neces- The daily maintenance dose varied from less than o 50 mg. The usual initial dose of ethyl bis- acetate was 600 mg. followed 8 hours later by ditional dose of 600 mg. On the second day of y, 2 doses of 300 mg. were most frequently used. otal amount given in the first 48 hours varied 300 to 2,400 mg., and the daily maintenance dose l from less than 150 to 1,200 mg. The most com- dose schedule of phenindione was 200 mg. di- into 2 doses on the first day, with 2 50-mg. doses e second day. The total dose given in the first 48 varied from only 125 mg. to as much as 650 mg., ne daily maintenance dose varied from less than 375 mg.

e following points of comparison were used: 1. A eutic degree of prolongation of the prothrombin was effected more quickly with phenindione than cyclocumarol. For all practical purposes, phen- ne was as rapid in its action as ethyl biscoumace- 2. Patients receiving cyclocumarol and ethyl umacetate showed greater and more frequent ations in their prothrombin times during mainte- therapy than did those receiving phenindione. e percentage incidence of hemorrhage was great- the patients treated with cyclocumarol. 4. In groups of patients the response of the prothrom- ime to vitamin K was the same, but in some nts receiving the longer-acting drug, cyclocu- l, the prothrombin time subsequently lengthened necessitated repeated administration of the vita- These findings suggest that phenindione is a satisfactory and more easily controlled antico- nt than either ethyl biscoumacetate or cyclocu- l.

GERY

cal Indications in Cerebral Hemorrhage. J. Guil- e, R. Roge, G. Mazars and A. Pansini. Presse méd. 7-829 (May 1) 1957 (In French) [Paris].

o-thirds of patients with untreated acute cerebral rrhage die during the first week. For this reason, necessary to operate as early as possible, not only ecial cases of hematoma at a late stage. Statistics ore than 10 years provide no accurate estimate of ercentage of patients saved through surgery. In eginning the authors treated surgically only subacute hemorrhages of pseudotumorous form, with a high rate of success. Later, they operated on patients with regard to the stage of their illness only. This included a series of cases usually considered hopeless. The complications of treatment and of systematic hibernation render more difficult evaluation of these data. The study of the series of 150 acute and severe vascular accidents treated surgically by the authors shows that in 22 patients with ischemic lesions there were 14 cures and in 128 with cerebral hemorrhage there were 87 cures. Seventy-five per cent of the latter 128 patients developed varying sequelae, either minimal or with unexpected functional recovery. These data stress the importance of surgery in spontaneous cerebral hemorrhage, the treatment of which should be based on elimination of the hemorrhagic focus. This should be done as early as possible, before signs of severe involvement of the cerebral trunk appear. Time should not be wasted on nonsurgical treatment; postponement of the operation is no longer justifiable. Age and arterial hypertension are not contraindications; however, severe azotemic nephritis or diabetic acidosis worsen the prognosis. The indication for operation is based on clinical and electroencephalographic examination and on arteriography and ventriculography as well. The operation is not serious in itself and consists in removing the clots and cerebral pulp through a narrow incision. The elimination of chronic azotemia and diabetes, along with the decrease of postponement of surgery, raises the hope that in the future there will be an increased rate of success or at least a decrease in mortality.

Valvular Pulmonary Stenosis with Intact Ventricular Septum: Clinical and Physiologic Response to Open Valvuloplasty. S. G. Blount Jr., J. van Elk, O. J. Balchum and H. Swan. Circulation 15:814-826 (June) 1957 [New York].

Thirty-eight patients with congenital valvular pulmonary stenosis were operated on with the aid of hypothermia and circulatory occlusion. The approach to the valve was transarterial, permitting plastic repair of the stenotic pulmonary valve with unimpaired vision and a dry operative field. Clinical and physiological studies were carried out before and after the operation in 25 of the 38 patients, 14 female and 11 male, between the ages of 1½ and 33 years. Of the 25 patients, 15 had an intact atrial septum and 10 had an associated functional or anatomic atrial defect. The first 3 patients were followed up for 3 to 3½ years, while the other 22 were followed up for from a few months to 3 years. Two of the 38 patients operated on died postoperatively; one, a 7-month-old infant, died suddenly and unexpectedly 12 hours after the operation, and autopsy was not permitted; the other, a 10-year-old boy, died 5 hours after the operation of a bleeding diathesis. This operative mortality of 5% compares favorably with that in patients operated on by the blind transventricular approach.

The results obtained in the 25 patients were considered superior to those obtained in patients operated on by transventricular approach. Only a minimal amount of actual valve substance was removed in the first 3 patients, and no valve tissue was excised in the last 35 patients. Auscultatory evidence of insufficiency of the pulmonary valve was occasionally noted. In the first 3 patients who have been followed for a period of 3½ years there has been no clinical nor physiological evidence that this minimal degree of pulmonary insufficiency is significant. The systolic pressure gradient between the right ventricle and the pulmonary artery was completely abolished in 17 of the 25 patients. A residual pressure gradient of more than 20 mm. Hg was present in the remaining 8 patients. The possibility exists that some valve cups, being fibrosed, were sufficiently rigid to obstruct blood flow in these patients, although adequate incisions had been made. Another explanation would be that an infundibular stenosis was present lower in the ventricle, although no evidence of it was found on exploration of the subvalvular area with the finger or with an instrument at the time of operation. The postoperative pressure tracings in 2 patients supported an additional explanation, namely, that obstruction to blood flow by the structures of a hypertrophied outflow tract of the right ventricle, resulting from the valvular stenosis, may be the cause of a residual gradient in some patients.

Slight to moderate pulmonary hypertension was observed postoperatively in 6 patients, although the pulmonary artery pressures were normal preoperatively. A definite explanation for this postoperative phenomenon must await further investigation.

Considerations on 200 Commissurotomies for Mitral Stenosis. G. Ceccarelli and C. A. Carlon. Minerva cardioangiol. 5:55-60 (March) (In Italian) 1957 [Turin, Italy].

The authors report on the results obtained in 200 patients subjected to mitral commissurotomy. Seventy-nine patients were male and 121 female. The lesion does not occur more frequently in women than in men. The larger number of women is due to the fact that it is easier to convince women regarding the necessity for and the benefit of operation. Four patients were below 9 years of age, 31 were 10 to 19 years old, 74 were 20 to 29, 53 were 30 to 39, 38 were 40 to 49, and 10 were 50 to 59. Stenosis was caused by rheumatic fever in 72 patients, by local infection in 43, by articular rheumatism and local infection in 49, by chorea in 12, and by an unknown cause in the remaining 24. Sixty patients had a good heart action, presenting a normal rhythm and no myocardial lesions; 79 had a fair heart action, with arrhythmia and a mild myocarditis; 69 had fibrillation and myocarditis. Seventy-four patients had a pure stenosis with fibrotic valvular edges; 64 had stenosis combined with mild insufficiency and fibrotic valvular edges; 43 had stenosis combined with insufficiency and hard valvular edges, which in some patients were calcified; 19 patie
a prevalent insufficiency. The patients with e
heart, tachycardia, arrhythmia, or fibrillation
treated with procainamide, digitalis, and quinid
some time before they were subjected to the ope
A knife was used in 20% of the patients, wh
others were subjected to a commissurolysis wi
finger. The heart was reached through an incis
the 4th left intercostal space. Very good results
obtained in 87 patients. Sixty-five patients dev
postoperative insufficiency; 44 patients dev
stenosis and insufficiency; 4 patients died. One p
died at the beginning of the anesthesia and a
after the opening of the thoracic cavity. The oper
is contraindicated while the disease causing th
nosis is still active and when roentgenologic ex
tion demonstrates massive calcification.

**Treatment of Stone in the Common Bile Duct. J
ford. Brit. M. J. 1:1202-1205 (May 25) 1957 [Lo**

A vertical, supraduodenal choledochoduodeno
was performed on 12 men and 19 women betwe
ages of 46 and 87 years with obstruction of the
mon bile duct by stone or by biliary mud. Th
was dilated in all 21 patients, and in most of t
was thickened and rigid. Sixteen of the patien
had 1 or more previous operations on the bilia
tem, but 5 patients had not been operated o
viously. One patient died of a massive pul
embolus on the 4th day after the operation.
other patients recovered, although their avera
was 66 years. Three of them died 15, 4, and
respectively, after the operation, apparently of
tions unassociated with it. There were no parti
complications in the postoperative period. In no
the patients was there any apparent leakage a
anastomosis. The freedom from symptoms was
prising; none of the patients had jaundice or
Air was seen postoperatively in a large part o
biliary passages of several patients. A barium mea
seen to go into the ducts for a considerable dis
but it soon came out. In one of the patients the
tract was outlined by air in the postoperative
genogram taken after a barium meal in the
position. As soon as the patient was placed i
supine position, the barium refluxed up the bile
which appeared rather dilated. It might be advi
to let the patients who have had a choledoch
denostomy not to lie down after a meal until suffi
time has elapsed to allow the stomach to empty

A vertical, supraduodenal choledochoduodenos
is an operation which gives good results, with free
from symptoms afterwards. It is very valuable i
tients who have recurrent stones or biliary mud
thickened, dilated common bile duct when prev
operations have been done. Performance of c
dochoduodenostomy is also probably sound pra
any patient in whom the duct, in addition to b
dilated from obstruction by stones, is thickened

from chronic inflammation, even though no pre- ; operation has been done. This operation is not ;ed when the duct appears healthy. even though ntains stones.

macological Asystole in the Surgery of the nguinated Heart: Experimental Research in Hy- ermia. P. Goffrini, E. Zanella, E. Botti and A. cchia. Chir. e pat. sper. 5:209-233 (March) 1957 Italian) [Milan, Italy].

rug-induced asystole during operation on the ex- guinated heart was studied in 12 dogs weighing o 20 kg. each. Some dogs received an injection into bulb of the aorta of 1 cc. of 5% potassium chloride kilogram of body weight. The body temperature he dogs was reduced to 25 to 28 C. The injection sed arrest of the heart for a period of 6 to 12 utes. Fibrillation, which could not be checked by of the usual procedures, began as soon as the ulation in the heart was restored. A second group animals were given injections of 25 to 35 mg. per gram of body weight of potassium chloride. Con- ctions of the heart were not arrested, and fibrilla- n developed immediately. A third group of dogs eived the drug associated with physical maneuvers reanimation. All dogs died because of an eventual est of the heart after a period of irreversible ven- ular fibrillation.

A second study was made in 17 dogs operated on der general anesthesia with barbiturates. The body nperature of the animals was reduced to 22 to 29 C. e dogs were given an injection into the bulb of the ta of 10 mg. per kilogram of body weight of acetyl- orine. Asystole was maintained for a period of m 8 to 20 minutes. Cardiac systole could be restored thout any complications. Asystole was obtained thout marked depolarization. The authors think at acetylcholine prevents damage to the myocardium ich might result from biochemical and physical mage caused by ischemia.

ccessful Treatment by Nephrectomy of Hyperten- n Resulting from Aorticorenal Embolus. P. W. ne, J. B. McNally, J. W. Lord and others. New gland J. Med. 256:1076-1079 (June 6) 1957 [Boston].

In several well-documented cases of hypertension, struction of the renal artery has been chronic due arteriosclerosis or thrombosis in the renal artery or the aorta adjacent to renal arterial orifices. Primary atment is nephrectomy, resulting in prompt re- ssion of hypertensive symptoms, although equivocal ults have been obtained after thromboendoarterec- ny of the aorta with curettage of the renal artery bilateral arterial homografting of the renal arteries. e patient observed presented symptoms of hyper- nsion and nonfunction of the left kidney 10 days er resection of a thrombosed abdominal aorta. Hy- rtension was supposedly due to embolization of a fragment of thrombus from the aorta into the artery coincidental to curettage of the abdominal aorta at the level of the renal artery orifices. An alternate suggestion is that occlusion of the same artery is due to the occurrence of a complete thrombosis in the already partially occluded left renal artery resulting from the 20-minute period of aortic occlusion proximal to the renal arteries. Hypertension was reduced immediately following nephrectomy and remained within normal ranges for 17 months commensurate with functional improvement of the remaining kidney.

Comparison of Side-effects After Partial Gastrectomy and Vagotomy and Gastro-enterostomy. H. T. Cox. Brit. M. J. 1:1211-1214 (May 25) 1957 [London].

The side-effects in 100 patients who have had partial gastrectomy for duodenal or anastomotic ulcer were compared with the side-effects in 100 patients with duodenal ulcer treated by vagotomy and posterior gastroenterostomy. Each type of operation was carried out in comparable and unselected cases. Of the 100 patients subjected to partial gastrectomy, 83 had duodenal ulcer and 17 had anastomotic ulcer after posterior gastroenterostomy or pyloroplasty. The average time between the date of operation and that of the follow-up examination was 4 years and 5 months. No regurgitation or negligible regurgitation occurred in 95 patients. Fifty-five patients were able to take a normal-sized mixed meal, and 45 were not able to do so. Thirty-five patients, 6 of the group of 55 and 29 of the group of 45, were deprived by partial gastrectomy of their ability to take a dessert. Dumping, i. e.. attacks consisting of vertigo, weakness, palpitation, and sweating, occurred in 19 patients. and in 13 of these dumping was directly induced by milk, milk puddings. fatty foods, eggs, chocolates, and pastries. In 3 of these patients, dumping was, in addition, produced by a large meal.

The average time of postoperative follow-up in the 100 patients subjected to routine abdominal vagotomy and posterior gastroenterostomy with the stoma in the pyloric antrum was 2 years and 9 months; 92 did not have regurgitation or had only negligible regurgitation. Seventy-seven patients were able to take a normal-sized mixed meal and 23 were not. Nine patients, 1 of the group of 77 and 8 of the group of 23, were deprived by vagotomy and gastroenterostomy of their ability to take a dessert. Dumping occurred in 12 patients, and in 6 of these dumping attacks bore a definite relation to meals, 2 having dumping after hot milk, 1 after "horlicks," 1 slightly after fatty foods, and 1 after the midday meal irrespective of its nature; 1 had 2 attacks a month, usually after breakfast. Selective impairment of digestion after partial gastrectomy occurred in 30 who were not able to take milk, in 30 not able to take milk puddings. in 25 not able to take fatty foods, and in 20 not able to take eggs. Selective impairment of digestion after a vagotomy and a posterior gastroenterostomy occurred in 7 who were not able to take milk, in 10 who were not able to take milk puddings, in 17 who were not able to take fatty foods, and in 14 who were not able to take eggs.

There is no material difference in the incidence of biliary regurgitation after a partial gastrectomy and that after a vagotomy and a gastroenterostomy; the incidence of dumping is less after vagotomy and gastroenterostomy. The outstanding advantage of vagotomy and gastroenterostomy over partial gastrectomy is in the nutrition of the patient; more patients take a normal-sized meal, more patients take a dessert, and fewer patients suffer from a selective impairment of digestion—and the difference in all 3 points is substantial.

NEUROLOGY & PSYCHIATRY

Acid-Base Balance of Patients in the Respirator Because of Respiratory Paralysis Due to Poliomyelitis.

W. Droese, H. Stolley and H. Cailloud. German M. Month. 2:132-136 (May) 1957 (In English) [Stuttgart, Germany].

The acid-base and water metabolism were measured in 5 patients with poliomyelitis with a purely spinal respiratory paralysis without severe complications, who were placed in a respirator. Fluid balance and blood carbon dioxide, oxygen, chloride, sodium, potassium, alkali reserve, and pH were determined. An ionogram was constructed from these data in each case. Ventilation and various measures of treatment were adjusted accordingly. In the first patient, a 21-year-old man, electrolyte and oxygen values illustrated the response in acid-base metabolism during the initial period when the patient was placed in the respirator. The electrolyte pattern in the second and third patients, a 36-year-old man and a 27-year-old woman, served as examples of the response of the acid-base balance during the maintenance period of artificial respiration. The last 2 patients, a 14-year-old boy and a 24-year-old man, illustrated the problems connected with the "withdrawal" period when they were taken out and kept outside the respirator.

The observations in these patients indicated that electrolyte and water balance in respiratory paralysis caused by poliomyelitis are affected even if there are no complications. In the initial period of artificial respiration the patient passes from *respiratory acidosis* to *metabolic alkalosis*. Any respiratory acidosis requires an increase of blood bicarbonate for restoration of acid-base balance. The increase of blood bicarbonate in respiratory acidosis is physiologically due to a decrease of chlorides and organic acids. Respiratory acidosis in the initial perod of artificial respiration differs from the physiological reaction by an even greater decrease of plasma chlorides than would correspond with the increase of bicarbonate. This hypochloremia runs parallel to a minimal elimination of chlorides in the urine. Depletion of chlorides occurs if artificial respiration is initiated late or is inadeq The loss of chlorides results from increased eli tion of urinary chlorides before the initiation of a cial ventilation and coexisting respiratory acidos addition, it is due to a more or less severe dis associated with inadequate food intake; as the ion concentration in the blood remains normal anion deficit due to the decrease of chlorides mu leveled off by the body through an increase in the radicle. During the maintenance period of arti *respiration the patients are usually* hyperventil Not all difficulties are overcome by avoiding ch respiratory alkalosis and maintaining adequate v lation. *Febrile illness*, myocarditis, and pulmo disease lead to an increase of carbon dioxide ten in the blood; in this way, without changing the r and depth of respirator action, respiratory acidosis develop. This danger becomes greater the longer the more pronounced the lowering of bicarbonate a respiratory alkalosis. A frequent error during the w drawal period is to allow repeatedly the frequ alternation from respiratory alkalosis to acidosis, w is due to *inadequate* autoventilation of a patient, w hyperventilated in the respirator, is forced to dep too much on his own respiratory effort in the inten ing period outside the respirator. A characteri metabolic disturbance may then develop into a c comitant metabolic and respiratory acidosis.

Deviations from normal ventilation are unavoida *in patients with bulbar poliomyelitis when* they first artificially ventilated in the respirator, dur maintenance of artificial ventilation, and when be weaned from it. A large number of clinical sympto *is caused by a disturbed water or electrolyte* bala It is urged that, in addition to the customary con of clinical and respiratory features, acid-base a water balance be regularly determined.

Recent Observations on Temporal Arteritis (with sideration of the Literature Since 1949 and 2 Observations).

K. Panter. Deutsche Ztschr. Nerv 176:219-232 (No. 2) 1957 (In German) [Berlin].

Temporal arteritis occurs in persons of adva age, showing a steep rise in incidence in person tween the ages of 55 and 60 and a peak around 70th year of life. Histological studies on the e vascular system, as well as biopsies from various v cular regions, revealed temporal arteritis to b systemic rather than a localized vascular disease. T arteritic process originally involves the tunica m and for this reason it has been identified anatom as mesarteriitis granulomatosa gigantocellularis. The classic clinical concept of temporal arteritis charact ized by pulseless, hardened, tortuous, and extrem painful temporal arteries accompanied by a h erythrocyte sedimentation rate, anemia, and prog sive cachexia has been greatly extended since t involvement of other vascular regions has been rec nized. These patients may have gangrene of the emities and meningitic symptoms, and some may ecome blind without apparent involvement of the emporal arteries. Involvement of the eyes is the most equent complication of temporal arteritis; it occurs n from 30 to 50% of the patients.

The first of the 2 patients with temporal arteritis hose histories are described had miotic pupils and tosis of the left upper eyelid and, after about a year, eveloped an irreversible amaurosis and total atrophy f the optic nerve. The persistence of pain in the neck nd in the heart together with the accelerated erythrocyte sedimentation rate suggested that the occipital nd coronary arteries were involved in the arteritic rocess. The second patient first presented signs of a ymptomatic depression, and after that the arteritic rocess in the temporal arteries became evident. In he course of the further deterioration the patient had a severe hepatitis with retarded convalescence. Psychological and neurological manifestations should lways be thoroughly investigated, because these may e brought on by senility and cerebral sclerosis. The rteritic process probably often involves the cerebral rteries. The morphology and the development of temporal arteritis is decisively influenced by arteriosclerosis. On the basis of the most recent observations temporal arteritis belongs to the group of rheumatic or pararheumatic disorders. This concept is further corroborated by the striking therapeutic results obtained with corticotropin and cortisone.

Epidemiology of Poliomyelitis: Investigations in the Population of Basel and in Some Military Units of Switzerland. **E. Berger, J. Marti and B. von Deschwanden. Schweiz. med. Wchnschr. 87:589-593 (May 18) 1957 (In German) [Basel, Switzerland].**

Epidemiologic and serologic investigations and the demonstration of neutralizing virus antibodies were carried out in the Canton of Basel and in several military units. The spread of poliomyelitis in Basel is limited and slow. This is partly due to the relatively high standard of living in the population, with a correspondingly high degree of sanitation. A more frequent occurrence of virus neutralizing antibodies was found in families in whose living quarters bathing facilities were not present. All 3 types of poliomyelitis virus were completely absent in 23.5% of the age group 10 to 11, and only 17.6% possessed antibodies against all 3 types. Poliomyelitis virus type 1 was found the most common infectious agent of poliomyelitis in the age groups 0 to 2, 5 to 6, and 19 to 24. The smaller distribution of virus types 2 and 3 might be of subsequent epidemiologic significance. The high contagiousness of the poliomyelitis virus observed in the younger age groups and demonstrated by the complement-fixation test was also found in military units, in which a case of poliomyelitis occurred. The frequency of clinical compared with inapparent infection was very low, despite the high contagiousness of this disease. Half of the persons in the military units, consisting of 28, 105, and 280 men, respectively, were recently infected by poliomyelitis virus, but only 3 clinical cases occurred. Only 15% of 475 persons without any demonstrable contact in Basel city were recently infected, thus indicating the low index of contagiousness and the easy transmission of the poliomyelitis virus in the population of a city. The index of contagiousness of poliomyelitis for the year 1956 in Basel was 1:190 to 1:290.

GYNECOLOGY & OBSTETRICS

Cortisone and Specific Antibiotics for Resistant Pelvic Infections. A. Hurtig. Am. J. Obst. & Gynec. 73:1183-1186 (June) 1957 [St. Louis].

Forty-five selected female patients with resistant pelvic inflammation were given combined treatment with anti-inflammatory adrenal cortical steroids and proved specific antibiotics. Twenty patients with resistant gonorrheal cervicitis and recurrent salpingitis were completely cured. Ten of these were followed up for from over 3 to 6 years. In this group there were 5 pregnancies, 1 of which, however, was ectopic. Some of these patients had been ill for 1 year or 2; relief of pain in all was complete. The so-called chronic cervicitis, which is really a subacute lesion, cleared completely in all these patients. Excellent results were obtained in patients with chronic endocervicitis. When deformity, tear, hypertrophy, or Nabothian cyst or scar formation had occurred, temporary remissions only could be obtained. Twenty patients with postpartum, postabortal, or postcauterization pelvic cellulitis, with or without tubo-ovarian abscess, all had complete remission. The amount of residual damage by scar depended directly on the duration of the disease before combined treatment. Five patients with generalized peritonitis with intestinal obstruction were successfully treated. There were no deaths. Complications of steroid therapy occurred in many patients but subsided as the dosage was decreased.

The combined use of cortisone and proved specific antibiotics will hasten cure in patients with resistant pelvic infections. The earlier this combined treatment is practiced, the less will be the final total tissue damage. The more acute the lesion, as indicated by cervical discharge, tender granulation tissue, fever, leukocytosis, and elevated sedimentation time, the more immediate and permanent are the benefits of such treatment. The lesions will not recur if therapy is adequate and is practiced early enough. The combined treatment is the method of choice for resistant gonorrheal lesions and early tubo-ovarian abscess after pelvic cellulitis. Accessible abscesses should always be treated by early, adequate surgical drainage. Once scar tissue has been laid down, the combined treatment is of no value. Repetition and confirmation under similar conditions by other workers is recommended. Until that time, treatment should be considered experimental and used only under the most careful supervision.

Endometriosis in the Vaginal Scar Following Hysterotomy for Therapeutic Abortion: Report on 100 Cases. T. Gottlieb. Acta obst. et gynec. scandinav. 36:194-208 (No. 2) 1957 (In English) [Stockholm].

The author reports on 100 women with endometriosis in the vaginal scar after hysterotomy for therapeutic abortion. The endometriosis did not cause discomfort in 28 patients. Sixty-one of the remaining 72 patients had *dysmenorrhea*, 36 had dysuria, and 32 had dyspareunia. As a rule these symptoms were not noticed until some years after the hysterotomy, and only 3 patients felt discomfort in the first year after the operation. Vaginal speculum examination did not reveal bluish cysts on the front of the cervix in 58 patients, but one or more tender nodes or infiltrates were palpable on the site of the scar or in its vicinity in these patients. Moderate digital pressure in palpating this area of infiltration reproduced the abdominal pain which had caused consultation with the gynecologist. Of 67 patients who were checked for this symptom, 65 had it. Cystoscopy revealed that the infiltration had spread to the urinary bladder in 12 patients.

Fourteen patients with severe symptoms and widespread lesions were operated on. Ten of these became free from symptoms, 2 had recurrences, 1 was operated on too recently for evaluation, and 1 died after the operation. Twenty-five patients were given local treatment with androgenic hormone in microcrystalline suspension; 50 mg. of a proprietary preparation of *testosterone propionate* was injected monthly into the palpable lesion 8 to 10 days before the menstrual period for 3 to 5 menstual cycles. Eighteen of the 25 patients became free from symptoms. The most natural explanation of endometriosis in the scar after hysterotomy for therapeutic abortion seems to be the transplantation of groups of cells from the decidually transformed endometrium. Although there are many women in whom endometriosis in the vaginal scar after hysterotomy causes little or no discomfort, endometriosis must be regarded as a serious complication to which due attention should be paid when considering whether or not to perform therapeutic abortion by hysterotomy.

The Value of Irradiation Therapy in the Treatment of Endometriosis. A. Brosset. Acta obst. et gynec. scandinav. 36:209-225 (No. 2) 1957 (In English) [Stockholm].

The hospital records of 101 women with endometriosis treated by irradiation in the gynecologic department of the Radiumhemmet in Stockholm were studied. Ninety-seven were treated by conservative irradiation and 4 by x-ray sterilization. Conservative irradiation therapy consisted either of x-ray treatment with small doses of 100 or 150 r delivered to the lesion from 2 or more portals and repeated once or several times or in application of radium directly to the lesion through the vagina. Of the 97 with conservative irradiation therapy a diagnosis of ovarian endometr was made in 38, a diagnosis of endometriosis in t rectovaginal septum in 33, and a diagnosis of e metriosis in different places of the body such as vagina, right groin, labium majus, and umbilicus 26. The diagnosis in 84 patients was confirmed ei histologically or by clinical findings.

Sixty-nine of these 84 patients were subjecti and objectively free from *symptoms or* were marke improved after irradiation therapy. Fifteen patie were therapeutic failures. The menstrual period appeared after a period of amenorrhea of v length in 55 patients, and a permanent amenorrh resulted in 19. In the remaining 10 patients amenorrh had resulted from a previous hysterectomy before t institution of the irradiation therapy. Encouraging r sults were obtained with direct application of radi to the lesion through the vagina in a few patients w endometriosis in the scar after vaginal hysteroto performed for therapeutic abortion. The reported d justify the use of irradiation therapy on a larger sc than has hitherto been done in the treatment of tients with endometriosis in whom surgical interv tion presents difficulties.

Succinylcholine Drip in Cesarean Section. P. Kol and K. F. Schye. Acta obst. et gynec. scandinav. 233-249 (No. 2) 1957 (In English) [Stockholm].

The cases of 137 women delivered in 1952 *cesarean section with the aid of pure nitrous* ox ether anesthesia were compared with those of women delivered in 1954 by cesarean section with aid of anesthesia produced by a succinylcholine (2 per mille in dextrose solution) combined nitrous oxide and oxygen *in a ratio of* 3:1. Comp tions during anesthesia such as excitation, cyan secretion of mucus, and vomiting ocurred in 46.6 the patients given ether anesthesia as compare 21.1% in those given succinylcholine anesthesia. H orrhage, pneumonia, thromboembolism, and infe occurred in 46 patients, and hysterectomy was formed in 3 patients after ether anesthesia, a incidence of 35.6% of postoperative complicat hemorrhage, pneumonia, thromboembolism, and fection occurred in 32 patients (19.9%) after succ choline anesthesia, and hysterectomy had not ha be performed in any of these patients. Serious f asphyxia occurred in 8.5% and mild fetal asphyxi 3.6% as a result of ether anesthesia, while the co sponding figures for succinylcholine anesthesia w 0.77 and 2% respectively. The corrected infant mor ity rate was 0.8% in the group with ether anesth against no infant mortality in the group with succi choline anesthesia.

Succinylcholine drip combined with administrat of nitrous oxide appears to be an ideal method anesthesia in women subjected to cesarean secti Optimal working conditions may be provided for geon by this method, and the mother is exposed to inimal strain. Apparently succinylcholine does not a rule pass into the fetus in sufficient amounts to duce asphyxia. Nor is the contractibility of the rus observed to be influenced by the anesthetic. e method produces rapid induction, in about 3 nutes, and the patient is awake at the end of the eration. Succinylcholine may be used as an anes-tic agent in all types of cesarean section, regardless indications.

nital Endometriosis and Pregnancy. J. C. Ahumada, L. Sardi and L. A. Arrighi. Obstet. ginec. latino-ner. 15:15-26 (Jan.-Feb.) 1957 (In Spanish) [Buenos res, Argentina].

Pregnancy rarely occurs in women with genital dometriosis. Four hundred sixty-five patients with nital endometriosis were observed during a period 27 years in a Maternity Hospital of Buenos Aires. egnancy occurred in 17 patients. Five patients of 1 with internal uterine endometriosis became preg-nt. Pregnancy was intrauterine in 4 and ectopic tramural) in 1. Perforation of the walls occurred in of the patients with intrauterine pregnancy as a sult of therapeutic curettage. Pregnancy did not cur in any of the 90 patients with ovarian or external eritoneal endometriosis. Ectopic tubal pregnancy ccurred in 12 of 50 patients with tubal endometriosis. In the remaining 103 patients endometriosis was resent in structures rarely involved by this process nd in which pregnancy does not as a rule occur. The uthors make the following conclusions: 1. Internal terine endometriosis weakens the uterine walls dur-ng pregnancy, predisposing the uterus to spontaneous upture or to perforation during therapeutic curettage. . Internal uterine endometriosis may cause dystocia. It may also cause a severe atony, hemorrhage, and other severe complications. 3. Ovarian or external peritoneal endometriosis prevents the occurrence of pregnancy. 4. Tubal endometriosis is a frequent cause of tubal pregnancy. Endometriosis located in struc-tures which are rarely involved by this condition pre-vents, as a rule, the occurrence of pregnancy. Regardless of the site of endometriosis, pregnancy elicits a decidual reaction which stimulates the growth of the endometrial lesions. The reaction subsides when pregnancy is near full term. It is so marked as to simulate in some cases malignant proliferation of local tissue.

The Nature and Origin of the Mammotrophic Agent Present in Human Female Urine. G. Hadfield. Lancet 1:1058-1061 (May 25) 1957 [London].

The urine of normal premenopausal women, when injected into weanling males of certain strains of albino mice, induces growth response in their primitive mammary glands. The urine of 57% of normal postmenopausal women also contains this mammotrophic agent. The author cites experimental studies that suggest, but do not definitely prove, that the mammotrophic agent present in female urine is pituitary prolactin. Preoperative tests were carried out on 7 patients with metastatic breast cancer in whom hypophysectomy was under consideration. The urine of 3 patients was found to be mammotrophic, and hypophysectomy in these was followed by regression of growth in the tumor and its metastases. No regression followed the operation in the remaining 4 patients, whose urine failed to produce a mammary response in intact male weanling mice of a strain known to be sensitive both to urinary mammotrophin and to prolactin. These results suggest that an estimation of the mammotrophic potency of the urine, by providing information regarding the mammotrophic function of the hypophysis, might be of assistance in the selection of patients with breast cancer likely to benefit from hypophysectomy. Such a test, however, carries serious clinical implications, and it would be unjustifiable to advocate its use until more is known about the organ of origin of the mammotrophin in human urine. The investigations reported here were designed to solve this problem.

Experimental evidence was produced supporting the conclusion that human female urine contains pituitary prolactin at concentrations varying from 0.01 to 0.25 I. U. per milliliter. It is suggested that an estimation of urinary prolactin may materially assist in the selection of those patients with metastatic breast cancer who are likely to benefit from hypophysectomy. It is also suggested that, for the bioassay of prolactin in human urine, potent urinary extracts (which can be preserved indefinitely) should be injected into hypophysectomized male weanling mice of the Strong A_2G strain.

PEDIATRICS

Aortic Stenosis in Young Persons. E. W. Sørensen and A. Tryggeseth. Tidsskr. nórske lægefor. 77:386-388 (May 1) 1957 (In Norwegian) [Oslo].

Aortic stenosis in younger persons has usually been considered a rheumatic disease, but it is now believed that a congenital form exists. The disease is marked by a slow stage with few or no subjective symptoms. In recent years roentgenologic cardiac-aortic signs have been described which strongly support the diagnosis. In 6 of 14 children with congenital pure aortic stenosis Kjellberg and his associates found a localized distention in the suprabulbar segment of the ascending aorta, and in all cases there were increased pulsations in the ascending aorta, especially definite in the suprabulbar segment. As the patients grow older, calcifications in the valves are seen roentgenologically. Four cases of aortic stenosis in young persons admitted to Rogaland Hospital during the last year are described. The prognosis is unfavorable in cases of grave congenital aortic stenosis which give subjective symptoms in early childhood. Progressive cardiac failure, bacterial endocarditis, and sudden death may supervene. Patients with milder congenital aortic stenosis without symptoms in childhood can reach a high age, even though in most cases there is slow progression of the stenosis and now and then a mild degree of insufficiency.

A Study of Acute Respiratory Disease in Infancy. W. C. Taylor and C. H. Read. J. Pediat. 50:679-689 (June) 1957 [St. Louis].

One hundred infants of less than 3 years of age were studied during 2 6-month periods throughout the winter months of 1953-1954 and 1954-1955. They all suffered from respiratory infections sufficiently severe to require hospitalization. They were divided into 5 equal groups: the 1st group was given 0.1 Gm. sulfamethazine per pound per day; the 2nd 30,000 I. U. dipenicillin G dibenzylethylene diamine in addition to 0.1 Gm. of sulfamethazine per pound per day; the 3rd 10 mg. of chlortetracycline per pound per day; the 4th 10 mg. of oxytetracycline per pound per day; and the 5th 10 mg. of tetracycline per pound per day. No significant differences between the 5 groups were observed when failure rate, temperature response, and duration of hospitalization were compared. Minor toxic effects such as diarrhea, vomiting, and skin rashes were seen more frequently in the 3rd, 4th, and 5th groups. Sulfamethazine and sulfamethazine plus penicillin were more effective in patients with pneumococcic infections than broad-spectrum antibiotics.

Rheumatic Fever: Prevention of Recurrence with Penicillin Given Orally. B. Dowd and H. Walsh. M. J. Australia 1:598-602 (May 4) 1957 [Sydney, Australia].

Penicillin G was given continuously by mouth for an average period of 22 months to 46 boys and 40 girls with rheumatic fever. Of the 86 children, 68 had had 1 attack of rheumatic fever, 12 had had 2 attacks, 5 had had 3 attacks, and 1 had had 1 attack when they first received penicillin. One tablet consisting of 100,000 units of crystalline penicillin G with 135 mg. of cane sugar was given 3 times daily half an hour before a meal. A control group of 166 children with rheumatic fever did not receive penicillin by mouth, but some of them were given 0.5 Gm. of sulfadiazine twice a day for varying periods after their 1st, 2nd, 3rd, or 4th attack. Comparison of the 2 groups showed a significant reduction of the recurrence rate in the penicillin group. No side-effects were observed. No infection was caused by penicillin-resistant organisms. It was not possible to assess the value of penicillin in the prevention of cardiac damage in the rheumatic children. Prophylactic treatment against streptococcic infection should be given to all children with rheumatic fever or solitary chorea to prevent recurrence. Prophylaxis should be continued throughout childhood and adolescence and probably for longer.

Corticotropin (ACTH) Therapy of Nephrotic Sy
drome in Children: I. Clinical Results and Effects
Proteinuria in 106 Instances. F. U. Mateer, F.
Wegand, L. Greenman and others. A. M. A. J. D
Child. 93:591-603 (June) 1957 [Chicago].

Seventy-two children, 45 boys and 27 girls, with t
nephrotic syndrome, 60 of whom had depend-
edema or anasarca, were given 106 courses of trea
ment with corticotropin (ACTH). Patients with hype
tension, azotemia, and morphologic elements were
excluded. Corticotropin in amounts of 100 mg. a
occasionally 200 mg. in divided doses was given da
for 4 weeks, usually without interruption, and th
patients were maintained on diets containing 2 to
mEq. of sodium and 150 mEq. of potassium and we
given penicillin or other antibiotics prophylacticall
supplementary iron, and vitamins. A remission result
in 57 of the 68 children who are still living. The 9 w
failed to respond at least once included 3 pati
with chronic azotemia. Forty-eight patients were f
lowed up for 1 year or longer, and 30 of these we
followed up for 2 to 7 years.

Within this period there have been 4 deaths, n
of which occurred during corticotropin therapy:
patient died with terminal uremia, in 2 others br
chopneumonia was present at death together
moderate azotemia and endocardial sclerosis in
death resulted from septicemia caused by Micrococ
(Staphylococcus) pyogenes var. aureus and assoc
with purpura in the 4th. Twenty patients had 1
more recurrences after an initial satisfactory respo
and 18 were again well after retreatment. Of the
living children 50 are known to be entirely well a
1 or more courses of treatment and 7 others were
tirely well when last seen, but follow-up within
past 6 months to 1 year was not possible. Serious c
plications of corticotropin therapy included infecti
personality change, and transient steroid diabe
Systolic and diastolic hypertension usually appe
during treatment and may well have been a deci
factor in the occurrence of convulsions in 6 patie

The mortality figures to date suggest that ther
modification of the underlying course of the dis
in addition to control of the symptoms and signs,
vided one keeps in mind the custom in many se
collected from the literature of excluding "nephri
patients. Only adequate follow-up will determi
however, whether chronic nephritis may still

Corticotropin (ACTH) Therapy of Nephrotic Syndro
in Children: II. Laboratory Findings in 106 Instanc
T. S. Danowski, F. A. Weigand, L. Greenman a
others. A. M. A. J. Dis. Child. 93:604-614 (June) 19
[Chicago].

The authors report alterations in the morpholog
elements of the blood, in serum and blood solut
and in urinary reducing substances and 17-ketostero

re, during, and after 106 courses of corticotropin apy in 72 children with the nephrotic syndrome se clinical results have been described in the pre- ng paper. The leukocyte count in peripheral blood to an average of 12,000 to 13,000 per cubic milli- er during the 2nd, 3rd, and 4th weeks of therapy, hing values as high as 28,000 without evident in- ion; during this same period the average per- tage of polymorphonuclear cells increased to 72 n a pretreatment range of 56, with individual es as high as 96%; the metamyelocytes increased number while the lymphocytes fell. Pretherapy ues were attained within 1 week of the termination corticotropin administration. About 25% of the pre- atment whole blood nonprotein nitrogen concen- tions were above 40 mg. per 100 cc., pointing to presence of a moderate degree of renal failure. By third week of therapy all values had decreased to s than 50 mg. per 100 cc. despite the increased nitro- n load which accompanies corticotropin administra- n. After completion of the course only scattered ht elevations of the nonprotein nitrogen level were orded.

The fasting blood sugar levels increased during rapy and decreased to the pretreatment values at completion of the course. Concentrations above 4 mg. per 100 cc. were recorded in only 2 patients. 1 of these the blood sugar level of 370 mg. per 100 and the presence of persistent glucosuria without tonuria during the 4th week of treatment pointed the presence of steroid diabetes, which disappeared completion of the course of corticotropin. The ex- tion of unidentified reducing substances in urine reased during therapy. Hypoalbuminemia present varying degree in most but not all of the patients s gradually replaced by normal serum albumin lues beginning during the second week of treatment; casional patients also showed marked lowering of e serum globulin values which disappeared during rticotropin administration. Hypercholesterolemia as present in most patients; though the elevations of holesterol concentrations were almost always associ- ed with hypoalbuminemia, the reverse was not true. retherapy decreases in serum total carbon dioxide ontent and rises in serum potassium level could not lways be related to renal failure as reflected by azo- emia; during corticotropin treatment, the serum po- assium and chloride levels fell while the serum total arbon dioxide content rose. This pattern of hypo- otassemia-hypochloremia-alkalosis occurred despite arked restriction of sodium intake.

The tendency to pretherapy hyponatremia was not lways associated with hypercholesterolemia, pointing o the existence of hypo-osmolarity, undue water re- ention, or a new steady state as the probable causa- ion. Though precorticotropin hypocalcemia disap- eared during treatment as the serum albumin level ose, the serum calcium levels were not always low in atients with hypoalbuminemia. This suggests binding y globulins or alteration in the physical properties of albumin resulting in their precipitation as globulins. Corticotropin produced a lowering of serum inorganic phosphorus levels which disappeared at completion of therapy. Though the excretion of 17-ketosteroids usually rose, equally good clinical responses to corticotropin were observed in patients who did not show this change.

UROLOGY

The Use of Radioactive Gold Grains in the Treatment of Bladder Growths. J. G. Yates-Bell and C. Q. Henriques. Brit. J. Urol. 29:97-111 (June) 1957 [Edinburgh].

The majority of bladder tumors are radiosensitive, and the best results are obtained in cases in which some form of irradiation is used as an adjunct to surgery. At King's College Hospital total cystectomy is reserved for severe papillomatosis, for extensive carcinomas in situations where irradiation might result in fistula formation, and as a palliative in cases of persistent hemorrhage or pain. Partial cystectomy gives such bad results that it has ordinarily no place in the treatment of bladder tumors. The improvement in transurethral technique has led to the removal of small malignant growths by endoscopic resection, but for the larger neoplasms resection by the suprapubic route remains the operation of choice. Such resections should, whenever possible, be accompanied by interstitial radiotherapy. The development of numerous radioactive isotopes in recent years has led to the adoption of other sources of interstitial irradiation. In 1951 a repeater gun was introduced whose object was to implant small radioactive sources into body tissues with precision. Radioactive gold grains implanted with this gun are now being used for all interstitial irradiation of bladder tumors at this hospital, and a method has been devised whereby the grains may be implanted by suprapubic puncture or by transurethral and per vaginal puncture. Thus interstitial irradiation can be provided for the smaller bladder neoplasms. The isotope used is Au^{198}, and the grains, which are cylindrical in shape, measure approximately 0.5 mm. diameter by 2 mm. in length and are screened with 0.1 mm. Pt. The specific activity of each grain at the time of implantation is 4.5 mc., and the isotope half-life is 2.7 days. The dose given to the tumor should be between 6,000 and 7,500 r. The gold grains are activated in the atomic pile.

All growths should be resected by diathermy before gold grains are implanted, the aim being to leave a tumor base not more than 1 cm. thick. Three different methods of implanting the grains were used: insertion by suprapubic puncture in 12 patients; per urethram and per vaginam in 7 women, 5 of whom had advanced growths; and by suprapubic cystotomy in 31 patients. Suprapubic cystotomy should still be used for the larger growths, but the smaller ones may be treated by suprapubic puncture in the male and transurethral and per vaginal implant in the female.

Cures may be expected whether the bladder is opened or not, and relief may often be provided for hopeless cases. The object is not to replace open operation by closed methods but to widen the field of interstitial radiotherapy to include the small early growths at one end and the larger inoperable growths at the other, aiming in the first case at a cure and in the second at palliation.

Renal Artery Aneurysm: Report of 12 Cases, Two Treated By Excision of the Aneurysm and Repair of Renal Artery. E. F. Poutasse. J. Urol. 77:697-708 (May) 1957 [Baltimore].

Renal artery aneurysm is probably more common than autopsy or clinical reports indicate. Findings on 12 additional patients, observed since 1952, are presented. Aortography now provides the urologist with an accurate means of diagnosis of renal artery aneurysm and, with modern techniques of arterial surgery, many cases will be recognized and treated successfully. Seven of the 12 patients reported had a saccular aneurysm (one had multiple saccular microaneurysms associated with partial stenosis of the renal artery), 3 had poststenotic or jet aneurysms in association with hypertension, 1 had a fusiform aneurysm in association with a hypernephroma, and 1 had a large arteriovenous aneurysm. Aortography is a valuable means of establishing the diagnosis of aneurysm and of differentiating calcified arteriosclerotic plaques within the wall of the renal artery. Aortography has also proved of value in the demonstration of unusual noncalcified types of renal artery aneurysm in hypertensive patients. Excision of the aneurysm and repair of the renal artery were performed in 2 of the patients having congenital saccular aneurysm; postoperatively, normal renal function was demonstrated in each. It is believed that large, symptomatic aneurysms, especially in hypertensive patients, should be treated by excision or nephrectomy, whether calcified or not. Small, asymptomatic, calcified aneurysms in nonhypertensive patients probably can be followed without surgical treatment.

PATHOLOGY

Adrenal Lesions in Acute Meningococcemia. J. B. Thomison and J. L. Shapiro. A. M. A. Arch. Path. 63:527-531 (June) 1957 [Chicago].

Autopsies were performed in 27 patients whose deaths had resulted from acute meningococcemia. Of the 27 patients, 6 were not older than 1 year, 15 were between the ages of 1 and 19 years, and 6 were between the ages of 20 and 54 years. The authors' report is concerned only with the adrenal changes observed in these patients. The adrenals of 4 of the 27 patients were much increased in size, and on microscopic examination the more or less complete ablation of the cortex by massive hemorrhagic necrosis was observed. The hemorrhage affected first the zona reticularis gradually migrated outward until the entire c was hemorrhagic. The medulla was characterist spared. The adrenals of 10 patients showed mul small areas of hemorrhagic necrosis, which was a ciated with thrombosis of the sinusoids or l vessels in 5. Two of these patients showed da which was estimated to be almost as great as caused by massive hemorrhage. The 3 zones, i. e., z fasciculata, glomerulosa, and reticularis, tended t uniformly involved. Most of the patients with patchy type of necrosis also showed extensive tub degeneration, and 9 other patients showed tub degeneration alone. In contrast to massive hem rhage, tubular degeneration begins in the zona merulosa and is more marked here, gradually mo inward. The remaining 4 patients showed only min tubular degeneration and loss of cortical lipids.

The patients with massive hemorrhagic necrosis w not older than 2½ years, and all of them died wit the first 24 hours. It appears very likely that no pati survives bilateral massive hemorrhagic necrosis of adrenal, which tends to occur early in the cours meningococcemia. The results of these anatomic st ies as well as the clinical course of surviving pati suggest that adrenal lesions other than massive hem rhage are reversible, with complete restoration adrenal cortical function. Although acute meningoc cemia may occur at any age, it is much common young persons, particularly infants.

RADIOLOGY

Stratigraphy in the Investigation for Mitral Calcif tion. E. Rizzetto and G. Sablich. Minerva m 48:1223-1227 (April 11) 1957 (In Italian) [Turin, Ita

Body section roentgenography (stratigraphy) was p formed by the authors on 3 patients, 1 male a female, 28, 23, and 48 years old respectively, were to be subjected to a mitral commissuroto Roentgenologic examination in the frontal and la projections did not show the presence of intracar calcification. Calcareous shadows were observed tween the 10th and 16th plane by means of ant posterior stratigraphy and between the 5th and plane by means of laterolateral stratigraphy shadow the size of a peanut was observed in the f and third patients and a shadow approximately size of a small nut was observed in the second pat The density of the shadow was always marked but always uniform in the different planes. The sh was observed in all patients on the left of the media line; it appeared at the center of the heart in t laterolateral projection. Whether the calcificatio were on the annulus or on the valvular edges co not be determined. The authors think that calcific tions of the annulus or of the valvular edges are contraindication to mitral commisurotomy.

BOOK REVIEWS

Management of the Patient with Headache. By Perry S. IacNeal, M.D., F.A.C.P., Assistant Professor of Clinical ledicine, Jefferson Medical College, Philadelphia, Bernard . Alpers, M.D., Sc.D., F.A.C.P., Professor and Head of)epartment of Neurology, Jefferson Medical College, and Villiam R. O'Brien, M.D., F.A.P.A., Head of Department of 'sychiatry, Pennsylvania Hospital, Philadelphia. Cloth. $3.50. 'p. 145. Lea & Febiger, 600 S. Washington Sq., Philadelphia i, 1957.

It is surprising how much of interest and help ias been gathered between the covers of this uthoritative book. It is true that headache is a ymptom and not a disease, but this is an overimplification, since we are so often confronted y the question: A symptom of what? The paient comes to his physician for relief, and, if his is not quickly forthcoming, he makes the ounds of waiting rooms until he gets it. Hence, liagnosis is important but is often elusive and ndeterminate. Classification of headache is also lifficult, for the causes are many and varied. We nust keep in mind the possibility of such organic diseases as brain tumor or meningitis which nay be irreversible or even fatal. An error in judgment here may castigate a practitioner for life. Since the headache is almost entirely subjective, especially in its beginning, we can get little help from laboratory tests. Even roentgenograms are usually negative, but we may have to use them to satisfy the relatives or friends. Migraine is one of the severest types. These authors say that most patients can be helped by medication, chiefly derivatives of ergot. Much space is given to this dictum concerning usage and expected results.

Chapter 5 is, perhaps, the most important in the book, since it deals with differential diagnosis and treatment. Chapter 6 describes diagnostic techniques with detailed suggestions for history taking and the physical examination. The authors seldom use spinal tap, which they think is useless in all functional cases and may be indeterminate. They warn that, if during the procedure the respiration becomes changed, it is well to have a 10-cc. syringe ready with normal saline solution for immediate injection into the spinal canal.

Handbuch der Orthopädie in vier Bänden. Herausgegeben von Prof. Dr. G. Hohmann, Prof. Dr. M. Hackenbroch, Direktor der Orthopädischen Universitätsklinik Koln, und Prof. Dr. K. Lindemann, Direktor der Orthopadischen Universitätsklinik Heidelberg-Schlierbach. Band I: Allgemeine Orthopädie. Bearbeitet von C. Bischofberger et al. Cloth. 178 marks; $42.40. Pp. 1186, with 632 illustrations. Georg Thieme Verlag, Herdweg 63, (14a) Stuttgart N, West Germany; [Intercontinental Medical Book Corporation, 381 Fourth Ave., New York 16], 1957.

About 23 authors have contributed to this volume, the first in a series of four, that will constitute an orthopedic encyclopedia rather than a handbook. The book is well organized, and some chapters make delightful reading. This volume starts with an interesting chapter on the history of orthopedic surgery. Weill's chapters entitled Congenital Diseases of the Skeletal System and Other Bone Diseases are outstanding. Unfortunately, they are practically devoid of illustrations, especially in the part dealing with benign tumors. While this volume furnishes a thorough theoretical background and should stimulate thought, therapy has been neglected. Most chapters are presented in a clear and understandable manner. The chapter on metabolic diseases and that on osteoporosis due to trauma (Sudeck's atrophy) (here called dystrophy) deserve particular mention. Unhappily, one of the chapters deals with vegetative derailment (Entgleisung), a term unknown in English literature. The chapter on the fundamentals of orthopedic surgery is conspicuously redundant. The chapter on hereditary developmental disturbances is excellent. All in all, the material in this volume is good.

Principles of Epidemiology. By Ian Taylor, M.D., M.R.C.P., D.P.H., Principal Medical Officer (Epidemiology), London County Council, London, and John Knowelden, Lecturer, Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine, London. Cloth. $9. Pp. 300, with 26 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6, 1957.

Ever since the publication of Stallybrass' book, which never went beyond the first edition, there has been a real need for a textbook on epidemiology. The present volume, written by two highly competent English authors, goes a long way toward filling this gap. Purporting to deal with the principles of epidemiology, it contains a clear and at times somewhat simplified exposition of fundamental concepts. Though dealing chiefly with the infectious diseases, adequate attention is given to the application of epidemiological principles to the study of noninfectious conditions, especially to the degenerative diseases. The book is a most welcome addition that should find a place in the libraries of workers in preventive medicine and public health. It is unfortunate, however, that the publishers have set the price so high.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

QUERIES AND MINOR NOTES

POSSIBLE ALLERGY TO TUNA

To the Editor:—*Recently a baby ingested a small amount of tuna which was apparently spoiled. Two days afterward he broke out with an urticaria-like rash. This was accompanied by edema of hands, feet, and eyelids, and the urticarial lesions became hemorrhagic. The child was treated with antihistamines and cortisone and made a rapid recovery. Could the fish which he ate produce the symptoms of allergy? F. R. Crouch, M.D., Farmington, Mo.*

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—The edematous, urticarial nature of this response suggests that it is primarily allergic in origin, but it is rather unlikely that an allergic reaction of this degree of severity should have been delayed two days. There is a possibility that this may have been an acute allergic response to a more recent exposure.

Although urticarial responses may be on the basis of food allergy, bacterial allergy, or other causes, there is insufficient evidence here to establish causation. More data as to the nature of the spoilage would have been helpful. As either uncontaminated or contaminated tuna might have caused the reaction, one can only suggest a move to rule out the possibility of sensitivity to tuna. This could be answered by the trial ingestion of a small portion of freshly opened canned tuna.

Answer.—Tuna fish, spoiled or unspoiled, could produce the condition described. The symptoms are those of angioneurotic edema due to food allergy. Although the onset of symptoms was delayed, the prompt response to treatment with antihistamines and cortisone supports this interpretation of the manifestation.

In relatively rare instances fish is the offending and provocative factor in allergy. The published reports do not list tuna as an allergen, but there is no reason to exclude this animal product because it has not been described. As a rule it is difficult to discover the offending food by means of skin tests. It seems certain that tuna, whether raw, cooked, or canned, fresh or spoiled, could produce the condition described in an allergic child. The query states that the tuna was "apparently spoiled" but does not state whether it was canned in the United States. Neither does it state how soon after opening of the can the product was consumed, soon the content was examined, or how the spo was determined. Only by means of delicate che tests can spoilage be detected. The quality of control programs in force, either by specially tra cannery personnel or by outside official inspecto canned products, makes the likelihood of spoiled being canned and sold extremely remote.

PRENATAL EFFECT ON CHILD OF MOTHER TAKING THYROID

To the Editor:—*A 3-month-old girl has a ma exophthalmos. The most important point in the natal history is that the mother took 1½ to 2 gr (0.10 to 0.13 Gm.) of thyroid daily throughout pregnancy for weight control. Could the thy medication have any causal relationship to the ophthalmos of the baby? What should be the fu management for this condition?*

N. W. Nemiroff, M.D., Oradell, N.J

Answer.—Exophthalmos has been observed in fants born of exophthalmic mothers. This may be to exophthalmos-producing substance secreted by maternal pituitary. If this hypothesis is true, the must be assumed that this substance was secrete excessive amounts and also crossed the placental rier into the fetal circulation. Thyroid-stimulating mone apparently does not cross the placental bar and there is no experimental evidence at this that exophthalmos-producing substance does. H ever, if the latter substance did cross the place barrier, then one would also have to assume that mother had some type of thyroid disturbance.

It is stated that the mother received 1½ to 2 gr. of desiccated thyroid throughout her pregnancy weight control. Normally, during pregnancy, the m er has a mild degree of hyperthyroidism, and possible that in this particular case the condition hypothyroid, even though the mother received roid therapy. It is therefore conceivable that her tuitary was hyperactive and that excessive secre of exophthalmos-producing substance occurred. other possibility is that, if the mother had a hyp roid condition, insufficient thyroxin passed the pla into the fetal circulation, and the infant's own pi tary secreted an excessive amount of exophthalmo producing substance.

It is not stated whether the mother had exophth mos or whether she had evidence of hyperthyroidis This information might be enlightening, because co genital hyperthyroidism has been reported in infa

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

rn of thyrotoxic, as well as hypothyroid, mothers. addition to exophthalmos, most of these infants hibit goiter and other signs of hyperthyroidism. owever, Keynes (*J. Obst. & Gynaec. Brit. Emp.* 59: 3, 1952) reported the case of an infant with con- nital exophthalmos, without any signs of toxicity, rn of a mother who had a thyroidectomy for thyro- xicosis. The mother developed progressive exoph- almos postoperatively and gave birth to this infant e year later. Keynes adds: "Here, therefore, we see other example of a hormone transmitted through e placental circulation, though this time it is the yrotropic hormone acting only on the infant's orbits a clinical curiosity that has seldom, if ever, been served before."

It is assumed that the infant has been observed r possible local causes for exophthalmos, namely, mors, inflammatory disease, and congenital malfor- ation of the skull. If she is normal in all other re- ects, observation should be carried out for several onths for possible spontaneous recession of the exoph- almos and for signs of goiter and/or other clinical vidence of thyroid disturbance. Then thyroid func- on studies should be considered, including uptake f radioiodine (I^{131}), protein-bound radioiodine, and erum protein-bound iodine; possible chromatographic udy of the plasma for thyroid hormone and precur- ors might be undertaken. If these studies are not ractical, and there is no evidence of hyperthyroidism, he infant should be treated with desiccated thyroid, ⅛ to ½ grain (8 to 30 mg.) daily, depending on her olerance.

LOSS OF TOOTH ENAMEL

To the Editor:—*A woman, 34 years old, is losing the enamel of her teeth, which are becoming discolored and painful. She is the mother of two children, aged 5 and 2 years, and has no significant history or symptoms. She wore an orthodontic brace on her teeth when she was a child. What can be done for her?*

Louis Gold, M.D., Lido Beach, L. I., N. Y.

Answer.—Discoloration and loss of tooth enamel in an adult is usually of local environmental origin, owing to the materials which contact the teeth. The main nocuous agents in this regard are usually (1) excessive intake of lemon or other foods containing citric or malic acid, (2) use of excessive amounts of refined starches, e. g., hard candies, cough drops, candy-coated chewing gum, sugar in coffee or tea, or sweetened, acidified carbonated beverages, or (3) acid gastric regurgitation. Many other factors, such as change in pH or buffering ability of the saliva due to emotional tension, excessive drying from radiation involving the salivary glands or from mouth breathing, improper or inefficient tooth-brushing techniques, may be involved. In studying dietary intake, it is much better to have the patient keep a dietary diary for a full week rather than to rely on office questioning of the patient.

TREATMENT OF ONYCHOMYCOSIS

To the Editor:—*A patient has onychomycosis of the right hand which has been present for several years and is resistant to x-ray therapy. Scrapings of the nails have verified the diagnosis. There has been no improvement in the clinical state. Would further avenues of investigation and treatment be advisable?*

J. Allen Marshall, M.D., Lawrence, Kan.

Answer.—The treatment of onychomycosis is highly unsatisfactory because the primary site of infection is under the nail plate. Daily scraping of the nail followed by the application of fungicidal preparations may be effective when the involvement is limited to the distal portion of the nails. If only one or two nails are involved and if there is no chronic fungous infection of the hand, surgical avulsion of the affected nails should be attempted even though this procedure may frequently fail.

FUNGOUS INFECTION OF THE VAGINA

To the Editor:—*A 44-year-old woman has had a yeast infection in the vagina for approximately eight months. She had a supravaginal hysterectomy for leiomyoma several years ago. Treatment produces a temporary relief of symptoms, but the infection invariably recurs. The husband's prostatic secretions have been checked, but there is no contributory evidence. This patient has received Mycostatin orally, in addition to therapy with methylrosaniline chloride (Gentian Violet). Good results were obtained by cleansing the vagina with Septisol about three times a week. The patient will remain well for approximately two weeks; then the irritation will recur just as before. What is the best treatment for this condition and how may permanent relief be obtained?*

Alfred H. Hathcock, M.D., Fayetteville, Ark.

Answer.—The case, as described, lacks certain information which might be helpful for a more specific answer. In the first place, the infection is most probably not a yeast infection. Actually the true yeasts do not produce disease. It is assumed that the fungus is Candida (Monilia) albicans. It is assumed that the diagnosis is made on the clinical appearance of the vagina or by finding the mycelia in a wet preparation. Culture methods are not reliable means for the establishment of the diagnosis of these organisms.

The use of detergent and soap preparations is not significantly therapeutic for mycotic infections. Husbands are most unlikely to harbor these organisms in the upper urinary or genital tract, but the husband with a prepuce, and especially if he is a diabetic, may have a mycotic balanitis and thus repeatedly reinfect his wife.

Some postmenopausal women taking excessive amounts of estrogens may produce a vaginal mucosa heavily laden with glycogen-like material and hence be likely candidates for vaginal mycosis. Diabetics with unusually high blood sugar levels may also be predisposed to vaginal mycosis. Even though the urine may be normal on the reduction test, it may be desirable to do a glucose-tolerance test to exclude diabetes. As yet there is no proved virtue in treating the gastrointestinal tract, for many people carry these organisms in this system. The fungi are found on some foods, and therefore a temporary exclusion from the gastrointestinal tract is the most that could be expected. Aci-jel, dispensed in a metal tube like a lubricating jelly, may be applied each night for a period of two to three weeks. (Use of methylrosaniline chloride may produce a chemical burn in an occasional patient.) Good results are to be anticipated, unless the patient has uncontrolled diabetes or unless she continues to receive excessive amounts of estrogens if they are being given. The withdrawal of estrogens will aid in the treatment of a vaginal mycosis.

NOMENCLATURE INTERPRETATION OF INTERNAL URETHROTOMY

To the Editor:—*What constitutes a proper definition of the urologic surgical procedure known as internal urethrotomy? Controversy now centers about the propriety of labeling the procedure in which the contracted female bladder neck is slowly, but nonetheless forcibly, dilated to 45 F. in caliber with the expanding Kollmann dilator as an internal urethrotomy. This procedure is believed by some local urologists to be a superior substitute for transurethral resection of the bladder neck in the female and is certainly not considered by them to constitute simple dilation of the bladder neck, since a dehiscence of the urethra and the bladder neck is to some degree effected. A member of the hospital audit committee states that an internal urethrotomy constitutes an actual cutting operation with a knife or an electrotome, while those who favor using the term to describe the procedure ask the question: How sharp must the knife be, and are not the four blades of the Kollmann dilator in effect separate knives producing a similar result?* *M.D., Texas.*

Answer.—The Kollmann dilator is a flexible urethral dilating instrument, invented a number of years ago. It is not considered to be a urethrotome. This instrument, by its passage, does cause a dehiscence or a breaking down of the fibers of a stricture of the urethra, and the procedure is coded in the Standard Nomenclature of Diseases and Operations as "740-840, Dilation of urethra by passage of sound." In order to differentiate this procedure from other somewhat similar procedures in which other types of sounds are used to dilate a stricture of the urethra, it is suggested that "Kollmann" be incorporated as part of the statement of the operative procedure by including this term within parenthesis. The Standard Nomenclature of Diseases and Operations does not consider the use of a Kollmann dilator as the equivalent of an internal urethrotomy.

ELECTRICAL CHARGE GENERATED BY THE BODY

To the Editor:—*A patient says that she is "charg and actually sparks with electricity. She gets wh is like an electrical sensation that starts in her kn and goes to her feet and sometimes up to her neck This has been a real problem to her in that she ca- not go to the movies because the seats feel charged Furthermore, she finds walking difficult; it is on when she walks on the beach without shoes th there is no problem. She has done a lot of experimenting on her own and finds that it makes n difference whether she wears all cotton or a mixtur of cotton, rayon, orlon, etc. Lately, when she ha gone walking, she has wrapped some wire around walking stick, and this has given her more comfort Are there any suggestions for the care of such patient?* *Martin Karr, M.D., San Mateo, Calif.*

Answer.—It is doubtful whether a properly placed ammeter would reveal any significant difference in th electrical charge generated by different human bodies Depending on variations in temperature and humidity most persons suffer from shocks and see sparks whe touching an automobile door or upon removing nylo pajamas. Just as one person tolerates pain less stoically than another, it is likely that this patient has a lowere tolerance to electrical shocks. Tranquilizers might rais this threshold. From the physical side, cotton clo may not be the entire answer, but they would contribute more to the patient's comfort than would nylo or similar fabrics. All-leather shoes, that is, those without any rubber or plastic in them, should be beneficial

FERRIC CHLORIDE TEST ON URINE

To the Editor:—*Recently in a case of phenylpyru oligophrenia in a 3-year-old child the ferric chlorid test on the urine was strongly positive, and the sam reaction has also been noticed in cases of leukemi What other medical conditions produce a positi ferric chloride test, and what is the mechanism in volved?*

A. Zaccaria Jr., M.D., Corpus Christi, Texas.

Answer.—The ferric chloride reaction is positive in many conditions. In cases of phenylpyruvic oligophrenia the addition of 5% ferric chloride solution to the urine produces a dark-green color. A similar reaction is seen in cases of thiamine deficiency with excess quantities of pyruvic acid in the urine. A transient blue or green color (Schiff's reaction) is also seen in the presence of alkapton bodies (e. g., homogentisic acid) with 2% ferric chloride solution. Phenol derivatives give an amethyst color with 10% ferric chloride solution. This consultant is not familiar with any such reactions in leukemia. The mechanism involved is presumably the oxidation of the pheno and/or pyruvic acid. The ferric ion acts as the oxidizing agent but, in so doing, is itself reduced (gain of an electron or loss of its positive valence) to the ferrous ion.

One should be specific in speaking of the ferric oride test, for many compounds can be oxidized by s reagent. Gerhardt's test for acetoacetic (diacetic) d in urine is based on the production of a cherry-red or with 10% ferric chloride; a similar color is pro- ced by various interfering substances, such as sali- ates, antipyrines, acetophenetidins, phenols, bicar- nates, acetates, and cyanates. In certain chronic sting diseases melanin in the urine reacts with 10% ric chloride to give a gray precipitate which will n black after exposure to air. This should not be mpared with the precipitation of ferric phosphate ien the ferric chloride is first added, before any lors are produced; the ferric phosphate is soluble dilute acid. The Kelling test for lactic acid in gastric ntents utilizes 10% ferric chloride with the produc- on of a canary-yellow color; the presence of thio- anates will give a more brownish or reddish color. ecently 5% ferric chloride solution has been used detect the presence of aminosalicylic acid (used in erapy of tuberculosis), resulting in a deep reddish- own color; a negative reaction is more significant, nce ketone bodies and salicylates also give a positive action.

REANESTHETIC MEDICATION FOR HILDREN

o THE EDITOR:—*There seems to be a difference of opinion among anesthetists and physicians as to the correct dose of atropine preceding a tonsillectomy in children. What is the correct method for calculating this dose, and how soon should it be administered prior to anesthetization?*

John P. Gifford, M.D., Vero Beach, Fla.

ANSWER.—The atropine should be given from a half-hour to a fraction of one hour prior to the time of induction of anesthesia. The chart, given below, is a rough guide of the patient's atropine requirements. Although many things may cause this dosage schedule to fluctuate, in general, the larger the body mass and the more vigorous the child, the larger should be the dose of atropine. This chart is based on an average weight factor.

Premedication in Infants and Children

Age	Weight, Lb.	Dem- erol, Mg.	Mor- phine Sul- fate, Grains	Atropine, Grains	Scopol- amine, Grains	Nem butal, Grains	Seconal, Grains
p to 2 mo.	7-10		None	1/400-1/300	1/650

INHERITED GENETIC DEFECT

To THE EDITOR:—*A 25-year-old married woman has congenital deformities of the hands and feet. These consist of short fourth and fifth metacarpal and metatarsal bones. These bones are 50% shorter than similar bones of the first three digits. The maternal grandfather, two maternal uncles, and the mother have similar defects. There is no history of any familial disorder in the husband's family. The patient is afraid to have children. She fears that her children may be born with even worse abnormalities. Her deformities are more marked than those of her mother or grandfather. What reassurance, if any, should the patient be given?*

Arthur M. Rogers, M.D., Charlotte, N. C.

ANSWER.—The skeletal abnormality described in this patient is rather clearly due to the effect of a dominant gene. Accordingly, the trait may be expected to appear in one form or another in half of the patient's children. There may be a considerable degree of variation in the expressivity of these inherited skeletal abnormalities. It is not possible to give the patient a clear prognosis concerning the possible range of manifestation in her children without more detailed information than is supplied in the query. Nevertheless, there is the real possibility that an affected child might show a more severe degree of defect than is present in the mother; there is, on the other hand, an approximately equally real possibility that the child might be less severely affected.

TOXICITY IN PLASTIC MANUFACTURE

To THE EDITOR:—*In a factory for the manufacture of polyester plastic resins, styrene and methyl ethyl keton (MEK) peroxide (60%) are used. The ventilation is poor. Can the fumes of these chemicals be obnoxious to the lungs or the blood?*

Theodor Friedrichs, M.D., Astoria, N. Y.

ANSWER.—Styrene is not regarded as a highly toxic compound. However, both the liquid and its vapor in sufficient concentration are irritants to the eye and respiratory tract. Prolonged exposure to high vapor concentrations is capable of producing systemic effects. The generally considered maximum allowable concentration for an eight-hour working day is thought to be 400 ppm by volume in air, according to the American Standards Association. The concentration 10,000 ppm may be fatal in 30 to 60 minutes because of respiratory tract irritation. Some of the inhibitors which must be used to check polymerization of stored or transported styrene may be toxic or irritating to the skin, but with good personal hygiene and good ventilation styrene can certainly be used without hazard.

Methyl ethyl ketone peroxide (60%) contains approximately 60% of this compound, and the balance is largely dimethyl phthalate. There is little information available about it in the literature because, to date, it has not found wide usage commercially. Its manufacturers state that its acute oral LD_{50} for mice (the dosage which will kill approximately half of the animals) is calculated to be 470 mg. per kilogram. Intraperitoneal toxicity was similarly determined; it apparently varied widely when the chemical was administered over seven successive days, but by this route the highest dose causing no fatalities was 65 mg. per kilogram. No information is available as to its irritant properties on the skin. However, it is known that dimethyl phthalate is poorly absorbed through the skin.

PROGRESSIVE LIPOMATOSIS

To the Editor:—*A patient, 26 years old, has been developing new lipomas at the rate of three to four every six months: they are mainly about the trunk, shoulders, thighs, and calves. Biopsies have been done on these fatty tumors on several occasions. Has any recent advance been made in the treatment of progressive lipomatosis?*

M.D., Pennsylvania.

Answer.—There are several types of lipomatosis, all of them progressive. There is no satisfactory method of treatment, and unless the lipomas become excessively large or undergo malignant change, it is best to leave them alone.

POLYCYSTIC KIDNEY AND AORTIC STENOSIS

To the Editor:—*A 65-year-old man has an aortic stenosis which seems relatively "tight." There is calcification of the valve on x-ray examination. The patient also seems to have a definite mitral regurgitation. He has been in grade 3 cardiac failure over the past year. Several cardiac surgeons have not considered him to be a suitable candidate for aortic commissurotomy. In addition, he has an unusual condition, namely, a huge left polycystic kidney which extends to the pelvic rim and is readily palpable both anteriorly and posteriorly. Competent urologists have ascertained that there is no function in this left kidney but that the right kidney is normal in function and shows no evidence of having a polycystic abnormality. The polycystic kidney at times is moderately painful and at times has bled. Would the removal of the left kidney and the subsequent abolition of its useless circulatory demands conceivably help the patient's heart condition by the shunting of this blood into more useful channels?*

M.D., Washington.

Answer.—The problem posed is that concerning the possible circulatory strain of a large polycystic kidney on a cardiovascular system with marginal reserve. True, a single polycystic kidney is indeed rare, and this consultant is not aware of studies of circulation through such a diseased organ. However, angiograms in such cases have indicated that the blood supply to such a polycystic kidney is indeed markedly diminished, and it is probable that only a very small amount of blood flows through such an organ. For this re it is doubtful that the removal of such an organ w reduce cardiac demands by any appreciable de It would appear that the indications for treatme the polycystic kidney would not be altered in direction of indication for removal but, rather reverse, by the severe cardiac condition whi present.

SODIUM CHLORIDE AS A CONTRACEPTI

To the Editor:—*For years a patient has been sodium chloride, 5-grain tablets, as a contracep with 100% success. She wants to know wheth use is harmful.*

M.D., Califor

Answer.—A jelly containing sodium chloride concentration of 10% or 20% has been found more spermatocidal in an in vitro test than mo the commercial contraceptive jellies or creams. vaginal application of these jellies for seven days no evidence of irritation subjectively or by spec examination according to Gamble (*J. A. M. A.* 1037-1041 [July 11] 1953). A saturated sodium ride solution (about 36%) introduced into the with a cotton wad for contraceptive purposes re in no signs of irritation by speculum examinatio

As the sodium chloride tablet, about whic inquiry is made, cannot produce a more-than-sat solution, the harmlessness of the tablet is sup by the tests cited. Since the saturated solution mild discomfort for some users, a lesser concent is to be preferred for contraceptive use. A half-sa ed solution (about 18%) can readily be prepar adding an equal column of water to saturated s chloride.

The contraceptive effectiveness of sodium ch is supported by the lowered pregnancy rates of of users in India and Pakistan. A 10% sodium ch solution was inserted into the vagina in a sponge, cotton wad, or pad or in a rice-jelly a with a syringe. Pregnancy rates were decrease 65 per 100 couples per year to 24. While this w complete protection, it was approximately the as the rate of 22 found for others in similar group used diaphragm and jelly. Many of the pregn may have resulted from omissions. A salt table contraceptive, therefore, appears noninjurious a least partially protective.

MASS IMMUNIZATIONS

To the Editor:—*Has the American Medical Ass tion adopted a policy concerning mass imm zations?*

Loran C. Grubbs, M.D., Scottsbluff, N

Answer.—It must be assumed that information cerning A. M. A. policy regarding mass immuniza refers to the Association's position concerning administration of poliomyelitis vaccine. The follow tement is the official action of the A. M. A. Board Trustees at its meeting on Dec. 14, 1956: "The M. A. is in favor of encouraging the administration poliomyelitis vaccine to the public, and is in mpathy with the efforts of those who are endeavorg to educate the public in its use. The A. M. A. will nd its efforts through regular medical channels ward the encouragement of such use by the general ıblic."

At no time has there been a specific policy position garding mass immunization. However, each county nd state medical association has been encouraged develop the inoculation program which best suited local situation. In some areas local societies elected use the mass immunization technique, while in hers they preferred that the inoculations take place the physicians' offices.

REATMENT OF IMPOTENCE

O THE EDITOR:—*A patient in his late 40's complains of complete impotence. He states that he was never too strong sexually, i. e., he has had occasional impotence ever since he was a young man. He noticed that this condition really became serious after the age of 40, and it has progressed until now, for the past three years, he has been unable to attain any erection whatsoever. This patient is a rather anxious type, worries a lot, and does sedentary work. His blood pressure is about 180/115 mm. Hg, with no symptoms; except for a mild prostatitis he is in good health. He was sent to an urologist, and prostate massage was done biweekly for three months, but no improvement resulted. The patient states that this condition has resulted in a strain in family relationships. He is going through the male climacteric, but the administration of testosterone has not helped. Is there any cure for impotence? Is the condition temporary or permanent?* *M.D., California.*

ANSWER.—The vast majority of men complaining of mpotence have no physical abnormality. This patient no exception. His history follows the usual pattern, period of relatively normal potency followed by a radual decline. Temporary remissions may occur, but he trend is toward complete impotence. In such intances local treatment either to the prostate or to the rethra has no beneficial effect. Administration of estosterone is equally ineffectual. As a matter of fact, such treatment may actually do harm because it leads the patient along the wrong path toward a solution of his problem. Proper management consists of a complete and frank discussion of the entire problem, during which the patient should be made aware of the emotional aspects of normal libido and potency. If he gets a clear concept of that, he will understand more readily the modus operandi of his premature sexual decline. The futility of both local and hormone treatment should be emphasized. If these measures fail, the patient should be referred to a competent psychiatrist.

RECURRENT, NONSPECIFIC PAROTITIS

TO THE EDITOR:—*A 27-year-old woman for the past several years has had swelling of the parotid and submandibular glands; this condition has occurred four times within the past year, apparently at the time of menses. The patient is afebrile; the upper respiratory passages are normal in appearance; and there is a mild associated depression and some discomfort caused by the "weight" of the glands, especially in swallowing. The glands return to normal size in a few days. What is the name and what is the treatment of such a recurrent mumps-like disease?* *M.D., New York.*

ANSWER.—Recurrent, nonspecific parotitis is the name applied to the condition described. It is known that increased activity of the salivary glands is many times associated with menstruation. Edema of the ducts interfering with the free flow of saliva would cause swelling without pain or fever. One author described a case which subsided during pregnancy but was again active with the resumption of menstruation. The use of one of the drugs given for dehydration in premenstrual edema may be of value. Allergic parotitis must be ruled out in this situation. The saliva is thick and ropy, with plugs which contain many eosinophils. A history of allergy, either individual or familial, can usually be ascertained.

SUBLIMATION OF SEXUAL URGE

TO THE EDITOR:—*What medical means may be employed to suppress the sexual desire? The question has arisen in connection with several patients who have utterly frigid wives but are reluctant to seek extramarital adventures. Is not this conflict, which may have serious consequences, much more frequent than is usually realized?*

Walter Newman, M.D., Springfield, Mass.

ANSWER.—This consultant knows of no authentic reports on medical means to suppress the sexual urge. That many celibates are able to suppress the sex drive is a well-established fact. In the majority of cases, this is accomplished by the process of sublimation, by which is meant the draining off of the libidinal urge into other channels that are emotionally satisfying. Since the sexual drive is primarily emotionally conditioned, it lends itself all the more readily to the process of sublimation. This method of finding an emotionally satisfying substitute is used consciously or unconsciously by many men and women who for one reason or another find it either impossible or undesirable to satisfy the sexual drive in the normal or usual manner.

The inquirer is correct in assuming that the sexual frustration produced in his patients as a result of their wives' frigidity and their own reluctance to seek satisfaction and release in extramarital relationships may lead to serious consequences. However, before focusing attention on what treatment to prescribe for the husbands, it is important to remember that frigidity in women is an abnormal condition for which there is a cause and which frequently can be relieved by appropriate therapy. In a minority of cases, frigidity in women may be due to pelvic pathology or to an endocrine disturbance, usually of a pluriglandular nature. In such instances, the nature of the pathological state or the disturbed function will indicate the type of therapy that is needed. However, in the majority of cases of frigidity in women, the cause is psychogenic in origin; hence, psychotherapy is indicated. If the patient should respond to this therapy, obviously the husband's problem will be solved. If, however, the woman should not respond or refuses to submit to psychotherapy, then the husband should be instructed how to sublimate his sexual drives.

ARCUS SENILIS IN YOUNG PERSONS

To the Editor:—*What is the present opinion regarding the prognostic significance of arcus senilis when observed in young men or women? Is there a proved relationship between this condition and premature aging or arteriosclerosis or even hypercholesteremia?* *M.D., Illinois.*

Answer.—It is generally agreed that the substance responsible for the appearance of an arcus senilis is cholesterol. In the elderly this is a degenerative process probably secondary to the obliteration of limbal vessels. However, it has been produced experimentally in animals fed a diet rich in cholesterol. It has also been reported frequently in young adults with familial xanthomatosis and hypercholesteremia. A monocular variety may occur after local injury to the eye. Although the bilateral appearance of an arcus in a young adult is not pathognomonic of premature aging, it es indicate the necessity for investigating the lipid etabolism and blood cholesterol of the patient.

HYPERTRICHOSIS

To the Editor:—*A patient, 18 years old, 5 ft. 9 in. (175 cm.) in height and weighing 150 lb. (68 kg.), complains of an excessive growth of dark hair, which is increasing in amount on face and body, particularly the chest and back. She recently lost 20 lb. (9 kg.) by dieting, but her chemical findings, pelvis, and general physical condition are normal. There has been no voice change or the development of other male characteristics. The patient has had electrolysis used on her face but has made no headway with this treatment. How should one proceed to treat this case, and what is the prognosis?* *M.D., Ohio.*

Answer.—It should be recognized that there is a great variation in the normal hair growth in women. Hypertrichosis is often familial, and rarely is there a sign of a pathological condition. All evidence indicates that hair growth is controlled by the endocrine glands, such as the gonads, thyroid, anterior pituitary, and adrenal cortex. Hirsutism has been known to oc after such diseases as mumps, encephalitis, neur and multiple sclerosis. Certain drugs, such as Dilar and testosterone, may also produce transient hirs ism. It is presumed that none of the latter were ca ative factors in this case, and it is presumed also th the patient, like the great majority of women afflict with superfluous hair, has no demonstrable hormo affliction. If that is so, there is nothing to be done b to treat the condition with electrolysis or diatherm if the thickness of the hairs warrants it.

TREATMENT OF ICHTHYOSIS

To the Editor:—*Is any information available relati to the treatment of ichthyosis? Have any of th corticosteroids or injections of histamine been us and evaluated in the treatment of this disease?* *W. F. Darkes, M.D., Orwigsburg, Pa.*

Answer.—The treatment of ichthyosis is still unsati factory; it consists of palliative measures, such as fre quent application of lubricants, use of nonirritatin soaps or soap substitutes and of bath-water softener avoidance of rough clothing and undue exposure t cold weather, and maintenance of a proper degree o humidity in the home. No reports of the use of cort costeroids or histamines for ichthyosis are known, an there would seem to be no rationale for their use.

DECREASED CLOTTING TIME

To the Editor:—*A 40-year-old man with rather hea responsibilities is being treated for hypertensi with reserpine, 0.25 mg. twice daily, and his con tion is adequately controlled thereby. He has rather short clotting time, less than a minute (L White method). What significance, if any, can attached to this clotting time? Does it indic stress? Does it raise the probability of serious v cular pathology, either causatively or as an indi tor?* *Alfred B. Mason, M.D., Concord, Calif*

Answer.—It is most unlikely that either essent hypertension per se, the administration of reserpi or "stress" might produce the extreme shortening the coagulation time described. The incidence vascular thromboses has not been increased, but pe haps reduced, in hypertensive subjects treated wi reserpine.

The clotting time of blood may be decidedly i fluenced by technical factors. If the validity of th accelerated coagulation reaction noted has been e tablished by carefully controlled studies, the pos bility of the presence of a thrombosing process o tendency must be considered. The use of anticoagulant therapy may be justified in some such circumstances the decision in this regard being influenced by the clinical, as well as the laboratory, features of the individual case.

Influenza Vaccine Allocation Plan

Immunization Limitations Under Medicare Program

Air Force Medical Consultants Complete Tour

Report on Dangers From Radiation

ALLOCATION PLAN FOR INFLUENZA VACCINE

The government has worked out a voluntary allocation program, similar to the one for the Salk poliomyelitis vaccine, for the equitable distribution of Asian influenza vaccine this fall and winter. Backing up a recommendation of the State and Territorial Health Officers, the Public Health Service announced that the six manufacturers of the vaccine had accepted the allocation proposal and are shipping vaccine in conformity with it.

Each state has been given a percentage figure based on the relationship of its population to the total population. On the important question of allocation to priority groups, the PHS again fell back on the health officers, who several weeks previously had proposed that states and communities establish advisory committees to recommend those who could get the vaccine first.

It has been suggested that first inoculations be given key personnel needed to provide medical care and to maintain other essential services. The allocation and priority plans also have been indorsed by the American Medical Association.

In explaining the PHS position, PHS Deputy Surgeon General Palmer Dearing declared: "Any one part of the nation is as vulnerable as another to a possible influenza epidemic. A program giving each state and territory its fair share of the vaccine seems to be the most equitable way of distributing the vaccine geographically throughout the country. As soon as supplies of the vaccine begin to catch up with demand, the allocation system may no longer be necessary."

Manufacturers report weekly to the PHS the total amount of vaccine released for sale that week and, on a state-by-state basis, the amount shipped to public agencies and to other purchasers.

The PHS will maintain the data from the states and will recommend modifications in allocations if its appears that supplies are exceeding demand in some states. The voluntary program does not apply to vaccine already shipped to fill military and civilian orders, but will apply to future civilian shipments, including any federal purchases for nonmilitary personnel.

The same day it announced the allocation program (Sept. 5) the PHS disclosed the release of 1,028,295 cc. of the vaccine, all for civilian use. It was being allocated according to the agreed upon percentages.

The PHS estimated that the release brought the *total since Aug. 12, when the Asian influenza vaccine* first became available, to 3,705,770 cc. The newest release included 300,030 cc. from Lederle Laboratories, 342,765 cc. from National Drug Company, and 385,500 cc. produced by Merck Sharp & Dohme.

INFLUENZA IMMUNIZATION UNDER DEPENDENT MEDICAL CARE PROGRAM

Under the military dependent medical care program (Medicare) Asian influenza vaccine will be administered at government expense only in military facilities.

In outlining the procedure, the Army, which is in charge of Medicare, laid down these rules:

1. Except in military facilities, patients will not be given influenza vaccinations at government expense.
2. In military facilities, vaccinations will be given at the request of the dependent, after military personnel have been vaccinated.
3. Because the State and Territorial Health Officers do not recommend vaccinations at under 3 months of age, vaccinations will not be approved in maternity cases, although all other maternity expenses are included.

The announcement, by Major Gen. Paul I. Robinson, head of the Army's Office of Dependent Medical Care, says:

"Immunization for this disease is a procedure normally administered on an outpatient basis. Consequently, dependents, including those receiving obstetrical and maternity care, will not be eligible to receive influenza vaccine at Government expense, except as may be provided for in medical facilities of the uniformed services. A recent resolution of the State and Territorial Health Officers indicates that immunization for infants under three (3) months of age is not recommended. Therefore, influenza vaccine for newborn is not authorized at Gov-

RED CROSS ASKS SUPPORT FOR INFLUENZA VACCINE DRIVE

The American Red Cross has asked its 3,700 chapters to give full support to medical and public health authorities in their plans for any influenza epidemic. Red Cross President Alfred M. Gruenther said in a statement that most chapters have in operation programs which he has asked be speeded up and incorporated into community planning to meet the threat of an epidemic. He listed these five ways in which local chapters can cooperate:

1. Through assignment of professional nurses already enrolled by the Red Cross to serve where needed during the emergency.
2. A continuous program of classes in care of the sick and injured, a 14-hour home nursing course for training students in care of the ill at home.
3. The new 40-hour course for volunteer nurses' aides who are trained to help doctors and nurses.
4. The reservoir of persons trained in these courses.
5. Enrollment of other trained Red Cross volunteers to assist with community-wide plans for combating the epidemic.

REPORT ON DANGERS FROM X-RAY EXPOSURE

"All man-made radiation must be regarded as harmful to man from the genetic point of view," according to a group of World Health Organization scientists who have completed a report on the effect of radiation on human heredity.

The study summarizes information on the subject and suggests lines for future research that promise to increase knowledge of the genetic effects of ionizing radiations on man and his decendents. It says in part: "There are strong grounds for believing that most genetic effects are very closely additive so that a small amount of radiation received by a large group of individuals can do an appreciable amount of damage to the population as a whole."

The report makes these points:

1. The genetic hazards of radiation from sources used in medicine, industry, commerce, and experimental science should not be underrated: "Both as an approach to control and as providing basic background information, it is essential that methods be found of recording exposures to individuals and populations, however difficult this may prove. There is reason to believe that radiation exposure can be much reduced; therefore, those in charge of sources of ionizing radiation should always ensure that there is adequate justification for exposing individuals to doses, however small."
2. An attempt should be made to develop efficient shielding of the gonads and, in addition, in every exposure the x-ray beam should, as far as practicable, be directed so that a minimum of radiation reaches the gonads.
3. Manifold precautions will have to be taken if nuclear energy is to be safely exploited, but "only the future can show how far the human race can live up to its responsibilities in this respect."

In a special document dealing with the research, Dr. Pierre Dorolle, WHO's deputy director general, cautions against using very high doses of x-rays in the pelvic region, explaining:

"The radiologist and the general practitioner alike will not fail to appreciate the serious implications of the recent warning of the UN committee, but it is to be hoped that they will be equally alive to other dangers, of which the scope and potentialities have not as yet been adequately assessed. Among such dangers is the hazard of exposing early human embryos to X-radiation. . . . If occupational irradiation does not exceed the accepted permissible weekly dose, there is very little reason to consider it a direct potential hazard to the embryo. The situation is different, however, for some types of medical application of X-rays."

TERCENTENARY OF HARVEY'S DEATH

The 300th anniversary of the death of William Harvey, the English scientist who discovered the principles governing circulation of blood, was marked by special observances at the National Institutes of Health on Sept. 17. Seven speakers delivered papers in a day-long symposium on Harvey and the historical and contemporary aspects of blood circulation. The National Heart Institute and the National Library of Medicine co-sponsored the program.

Speakers were Prof. Charles D. O'Malley, Stanford University; Frederick G. Kilgour, Yale Medical Library; Chauncey D. Leake, Ohio State University; Dr. André Cournand, College of Physicians and Surgeons, Columbia University; Dr. Theodore F. Hilbish, NIH; Dr. John H. Gibbon Jr., Jefferson Medical College; Dr. C. Walton Lillehei, University of Minnesota. An extensixe exhibit devoted to Harvey is on display at the Clinical Center at the NIH in Bethesda.

ADVANCED TRAINEESHIPS FOR NEUROLOGICAL RESEARCH

A new program of advanced traineeships for research scientists in neurological and sensory disorders has been announced by the National Institute of Neurological Diseases and Blindness. The project is designed to encourage advanced training in clinical basic science areas such as neurochemistry, neuropharmacology, neurophysiology, or neuroanatomy.

Individual awards will be made for not less than nine months or more than a year, although awards are renewable and may be continued for three years. Stipends which range from $5,500 to $14,800 a year are determined individually in accordance with each applicant's qualifications and training needs. Applicants must be U. S. citizens or have filed intent to become a citizen. The traineeships may be awarded for any institution in the U. S. or abroad qualified to give the training

Application forms may be obtained from the Chief, Extramural Programs Branch, National Institute of Neurological Diseases and Blindness, Bethesda 14, Md.

THE PHYSICIAN'S ROLE IN AIR TRAVEL

Lieut. Col. Frederick S. Spiegel (MC), U. S. Air Force

Physicians must continue to contribute to the safety, efficiency, and comfort of air travel. Three principles help to determine whether a person is fit to fly as a passenger: there must be no interference with the supply of oxygen to his lungs, the mechanical expansion of gases in his body must be unobstructed, and he must not affect adversely the sensibilities, security, and health of his fellow passengers. The frequency of airsickness and ear trouble is 5 to 10 times as great in children under 5 years as in adults. A woman during the ninth month of gestation must present a certificate, signed by her physician, stating that she will not deliver for at least 72 hours. Antiemetics, nasal vasoconstrictors, and oxygen are effective in combating nausea, preventing pain from ears and sinuses during descent, and alleviating true air hunger. Persons who have recently undergone enteric surgery must be considered carefully because of the effects of possible sudden decompression upon gases in the body. Aviation medicine has developed into a specialty, but prospective passengers generally turn to the physician in general practice. He must therefore be prepared to answer his patients' queries.

OVER 25 million revenue-paying passengers traveled on U. S. domestic airlines last year. The trend has been rising steadily, and forecasts reveal an even greater increase in the nber of air travelers in the next few years.

ven today there are legions who have had no exience with flying. These people frequently approach ticket window with ill-concealed trepidation and nb the ramp into the airliner with false gusto and vado. Anxiety is harbored by many, from the todig youngster to the timorous oldster. Since flying a new and mysterious event for them, a certain ount of fear is to be expected. All too frequently, vever, the fear is out of proportion to the situation. e trip becomes a nightmare.

Physicians can do much to allay these fears and rece some of the discomforts associated with flying. e should be of even greater usefulness in the role adviser when queried concerning the safety and visability of traveling by air. Most of the time we nember the basic physiology, vascular dynamics, d respiratory mechanics, and are qualified to give nd medical advice, a word of caution or a hearty ssurance. However, there have been instances in ich, in retrospect we must admit, we are not on too n ground. It is in these instances, I submit, that we ust be better prepared to assist with advice and inion based upon fact, not fancy. Several medical ools are now presenting courses in aviation medine and aviation physiology. These courses were made part of the curriculum as a result of the identification the need for this instruction. Since we are well into e "air age" and since air travel has grown so tremendously, it is incumbent upon all of us to become conversant with the medical and psychological problems associated with this type of transportation.

The guiding principles of the air transport industry are safety, operating efficiency, and passenger comfort. Safety is the first consideration. Many would-be passengers remember the glaring headlines concerning an

---

From the Air Command and Staff College, Air University, Maxwell Air Force Base, Alabama. Colonel Spiegel is now assigned to the Professional rvices Directorate, Office of the Surgeon General, Headquarters, United States Air Force.

airliner crash but are unaware of the millions upon millions of accident-free passenger miles flown each year. The Civil Aeronautics Board through its agency, the Civil Aeronautics Administration, maintains very close control over all airline operations, and, as a result, the safety consciousness of the operators is paramount. Safety takes precedence over all else. Safety devices, procedures, and maneuvers have reached a very high degree of development and perfection, and passengers' fears in this area are groundless.

The next principle is operating efficiency. This is closely allied with safety, in that one of the chief methods of achieving each is through extremely careful selection of airline personnel, both flight and key ground employees. Operating costs can mount disasterously and efficiency be greatly impaired if selection of personnel is haphazard, turn-over rates high, and replacements frequent. Further, both on the ground and in the air, errors are more frequent with individuals who are not physically fit or who are given tasks and responsibilities beyond their capabilities. If prospective passengers were made aware of the very stringent medical and psychological requirements airline personnel must meet and the continuous close supervision they must undergo, they would understand why air transport operations are among the most efficient in industry today.

The third principle of airline operation, passenger comfort, is closely related to revenue production. Passengers subjected to discomforts are unhappy and are poor salesmen for air travel. Also, an uncomfortable or depressed individual is more prone to physical symptoms, e. g., air hunger, airsickness, headache, or vertigo. Potential passengers should be assured of a pleasant and comfortable flight.

The aeronautic engineer, in concert with the aviation physiologist, psychologist, and flight surgeon, has been successful in overcoming many of the features of air travel that formerly caused discomfort for passengers. Pressurization of the aircraft has reduced the incidence of air hunger and headache that result from the decreased partial pressure of oxygen. Airsickness also has been reduced by pressurization, since the higher cruising altitudes are less turbulent. The occurrence of ear and sinus troubles are now unusual in pressurized cabins. With acoustic "sealing" of the passenger compartment, complaints referable to propeller and engine noise have been significantly lowered. Other factors in reducing illness and increasing comfort and security are the development and installation of reclining seats and efficient airborne air conditioning systems. The designing and production of dependable, stable, airworthy passenger aircraft with markedly reduced vibration characteristics is very significant.

The specialty of aviation medicine may be considered to consist of three main disciplines. These are categorized into, first, preventive medicine and public health; second, occupational and industrial medicine; and, third, aviation physiology, aviation psychology, and clinical practice. A survey of conditions and complaints of common occurrence in passenger travel reveals many instances when specific knowled these fields is invaluable. Examples will point requirement.

Physical Fitness to Fly

There are some medical conditions which re caution and the exercising of certain precautio preclude development of unpleasant and some serious complications. Three principles must be uppermost in the physician's mind when determ whether an individual is physically, emotionall mentally fit to fly. First, there can be no interfer with the supply of oxygen to the lungs. Next, med cal expansion of gases must be unobstructed. F one must always consider the effect that the indiv will have on the sensibilities, security, and heal his fellow passengers.

Commercial air carriers cannot maintain a "screening service" or triage, per se. They have successfully utilized their ticket sellers and fligh tendants to scrutinize patrons prior to boarding D ing flight the attendant may request that an be deplaned at the next stop, if such action is dee advisable in his or the other passengers' inter

Today, with the development of large, well-equip and well-staffed medical centers and clinics, many lines operate trunk routes into these areas. As a re a great number of passengers bound for these tions are, in reality, patients en route for diagnos treatment. Air travel is the fastest and, in most stances, the least fatiguing of any means of tion. The referring physician is frequently concerning the feasibility of traveling by air to clinic, and as an authority he must be able to accurate and pertinent advice. He should know example, that permission must be granted by public health officials before any person with a tagious or communicable disease may be trans across state lines. The airlines are wary of acce persons in whom communicable diseases are suspe and some refuse entirely. Suspected pulmonary t culosis is a case in point. There is always extan question of responsibility: if a state refuses to the admission of a passenger with a communicab contagious disease, the carrier may be held financ responsible for his care and return to point of or

Individuals with malodorous conditions, gross figurements, or other unpleasant characteristics w might offend fellow passengers should not be tr ported by public air carrier unless physical isol can be assured. Epileptics are more prone to con sive seizures when hypoxic in aircraft. Diabetic maintenance therapy may be carried only if their sulin and syringe are kept in their hand baggag the passenger cabin with them. Patients with artificial pneumothorax should never be allowed to soon after a refill; only after at least 10 days, and w the mediastinum fixed, should flight be considered

Physicians generally agree that a woman with uncomplicated pregnancy is not "sick," that she is normal individual undergoing a normal physiologic ess. All airlines accept passengers during the nth month of gestation and the majority will trans- those in the eighth month. In order to be accepted ng the ninth month, however, the passenger must ent a certificate, signed by her physician, stating she will not deliver for at least 72 hours. When- there is a question concerning premature labor her complications, a medical certificate is required to enplaning.

fants under 6 weeks of age are usually not trans- ed by commercial carriers unless there are very nuating circumstances. In this case a pediatrician's fication is requested, stating that the infant is thy and physically fit to fly.

ildren are only fair air travelers. The incidence of ckness and ear trouble is greatest in those under ars, 5 to 10 times more frequent than in adults. increased susceptibility to airsickness may be ed to position insecurity and apprehension. Ear omfort is associated with the difficulty in teaching lren to make the necessary oropharyngeal adjust- ts while descending. Wider employment of pres- zed aircraft has greatly reduced the incidence of e disabilities in the young traveler.

Medical Difficulties Encountered in Flying

ie changes in barometric pressure which occur changes in altitude are the basic reasons for ear culty. In the normal ear, equalization of the pres- between the middle ear and the ambient atmos- e occurs automatically upon ascent. During de- t, however, conscious voluntary actions (swallow- yawning) must be undertaken in order to gain maintain pressure equilibrium. This is necessary to the anatomy of the eustachian tube and its er-valve type of proximal orifice. Thus, since ear culty occurs almost entirely during descent, the nes routinely maintain a very gradual rate of ent. It is usually at this time that chewing gum istributed to the passengers, since chewing and llowing periodically opens the valvular pharyngeal of the eustachian tubes. Equalization of pressure he accessory nasal sinuses is basically automatic may be interfered with by such conditions as llen or redundant mucosa or nasal polyps. Upper iratory infections and affections are the chief etio- cal agents of aerotitis media, more recently titled titis media, and of barosinusitis. If individuals have such conditions as an acute respiratory ction, allergic rhinitis, or nasal polyposis must fly, expedient for them to use a nasal vasoconstrictor lecongestant during flight and particularly prior to nt and descent.

irsickness in adults is not a major issue in present- airline operations. However, discomfort and ial emesis are considerably more frequent in fe- es, occurring at approximately five times the rate ountered in males. As in children, this may be ibuted chiefly to anxiety and apprehension. Also, of airsickness itself probably hastens the develop- it and appearance of the characteristic symptom complex. Several effective proprietary medicaments are available which will reduce the awareness of motion and the concomitant discomfort in susceptible individuals. These also will prevent airsickness, in most instances, if taken in advance of flight. The value of reassurance cannot be over-emphasized.

Air hunger is associated with a lessened amount of available oxygen in the ambient atmosphere at higher altitudes, due to the decreased partial pressure of oxygen. True air hunger is physiological. Frequently, however, the diagnosis of air hunger is mistakenly associated with a dyspneic type of respiration which in reality is the result of apprehension or anxiety. The treatment of these two conditions is diametrically opposed. In true air hunger supplementary oxygen, which is always available on commercial airliners, will alleviate the symptoms. In the latter instance carbon dioxide inhalations or simple breath holding will bring prompt relief. Reassurance has a very beneficial and calming effect on both.

Potential passengers recovering from recent coronary thrombotic episodes or those suffering from coronary insufficiency must be carefully evaluated before being advised that they may fly. Whether the aircraft in which they will travel is pressurized must be determined. The same type of careful appraisal must be undertaken in the anemic patient, those patients in impending or recovering from cardiac failure, and those with any type of respiratory embarrassment. It is wise to have the individual notify the carrier in advance of the flight. Also, if he has in his possession a certificate of his fitness to fly, it may preclude his being refused passage at the last minute. One should remember that the commercial air carrier has the final word in determining who will be transported in its aircraft.

Persons who have recently undergone enteric surgery should be considered very carefully, with the fact kept in mind that the expansion of intestinal gases is approximately 50% at 10,000 ft. and 100% at 18,000 ft. The latter figure is of utmost significance in pressurized aircraft, since, with rapid decompression of the cabin due to failure of a window or hatch or malfunction of the pressurization system at high cruising altitudes, a postoperative catastrophe may occur.

Of recent and mounting interest is the problem of sickle cell anemia, which is found principally in Negroes. This hemolytic disorder is present in approximately 5% of the general Negro population. It has been demonstrated that with a mild to moderate circulatory oxygen deficiency, of the degree found in unpressurized flights at altitudes of from 8,000 to 14,000 ft., sickling and hemolysis may occur in those individuals with this trait. Splenic infarction or mesenteric thrombosis are the usual sequelae. Although the incidence of this condition is relatively low, it should not be overlooked. Negro passengers would be well advised to notify the flight attendant if they develop abdominal discomfort or pain. It is not unusual for a commercial airliner to make an emergency stop at an en route airport to place a passenger in the care of a physician.

Comment

The foregoing illustrations point out the manifold interests and responsibilities of the medical profession in regard to air travel. Physicians, in the capacity of both professional advisers and personal confidants, must have a firm foundation upon which to base their considered and valued opinions. As is common to all the medical specialties, certification in aviation medicine follows a long period of concentrated didactic and practical work and training in a highly technical field. Diplomates of this board are daily working intimately with flying personnel and aeronautic engineers—in fact with all those in pursuits related to aviation, civil, commercial, and military. Airline passengers almost never come in contact with the aviation medical specialist, and for good reason: he is concerned with the medical and allied problems of aviation—to make flight safer, more reliable, and more comfortable for more people. Medical practitioners in private practice are the ones to whom prospective passengers turn. The average physician should be more familiar with the answers to the questions and the solutions for the problems his patients pose concerning air travel. Several excellent texts and references on aviation medicine are readily available. Chief among these are Armstrong's "Principles and Practice of Aviation cine," [1] McFarland's "Human Factors in Air portation," [2] "Aviation Medicine Practice" pre by the Bureau of Medicine and Surgery of the ment of the Navy,[3] and the U. S. Air Force's Surgeon's Manual." [4]

Commercial air travel is expanding by leaps bounds. Higher-performance aircraft are being oped rapidly and continuously. Speeds are multipl and thus time and distance ratios are const shrinking. Before long jet-propelled passenger will be commonplace. Engineers are discussing ning, and designing the rocket airliners of tomorr Let us, as physicians, stay ahead of our patients' regarding traveling by air. Let us advance with technology of aviation.

INTESTINAL POLYPOSIS AND PIGMENTED SPOTS OF LIPS

HEREDITARY PEUTZ-JEGHERS SYNDROME

Lieut. Commander Lloyd C. Rohrs (MC), U. S. N.

Repeated episodes of abdominal pain in persons having melanin spots with a characteristic distribution can, with strong suspicion, denote existent intestinal polyps. Typically the melanin spots are on not only the lips and labial mucous membrane but also the buccal mucosa, occasionally the gingiva and hard palate, and rarely on the tongue. The pigmentation can also occur on the digits, periorally, about the eyes, and more rarely across the bridge of the nose. The condition has been reported in persons from childhood to the sixth decade, but usually appears as a recurrent intussusception in the second decade. It is to be emphasized that the polyps in this syndrome are to be considered premalignant lesions.

The association of pigmented spots of the lips, oral mucosa, and often the face and digits with intestinal polyposis has been recognized with increasing frequency as a distinct entity.[1] Repeated episodes of abdominal pain in persons having melanin spots with this distribution can, with strong suspicion, denote inexistent intestinal polyps, particularly of the small intestine, for at autopsy no patient having this pigmentation without associated polyps has been reported.[2] Complications of gastrointestinal bleeding, anemia, intussusception, and malignancy in this hereditary disorder have been stressed.[1] In view of these features, the following case is presented.

Report of a Case

A 22-year-old man first developed severe, generalized abdominal pain in May, 1954. It was unassociated with other gastrointestinal complaints. No abnormalities were present on

---

From the Medical Service, United States Naval Hospital, Oakland, Calif.

he initial examination or that performed 12 hours later. One pisode of vomiting occurred during the observation period. fter 12 hours the patient was asymptomatic. X-rays of the pper gastrointestinal area, in June, were "normal." In Decemer, the man was seen again because of nausea, vomiting, and pigastric aching pain. There were epigastric tenderness and igidity in the left lower abdominal quadrant. The white blood ell count was elevated, with 83% polymorphonuclear cells. bservation was continued for 48 hours, by which time the atient had become asymptomatic.

In March, 1955, he experienced the sudden onset of severe periumbilical pain. One hour later vomiting occurred. Abdominal tenderness, without rebound tenderness, and guarding over the upper right rectus muscle were found. Abdominal distention developed. An exploratory laparotomy was performed on March 31. There was hemorrhagic exudate in the abdominal cavity, and a distended loop of jejunum, 18 in. (46 cm.) in length, was seen. An estimated 60 in. (152 cm.) of jejunum was intussuscepted into itself. The entire loop had undergone a clockwise rotation of two and one-half turns. The intussusception began about 36 in. (91 cm.) from the duodenojejunal flexure. The terminal 60 in. of ileum appeared to have some impairment of circulation and was slightly cyanotic.

After reduction of the intussusception and volvulus, the reduced jejunum over the area of strangulation was edematous but appeared to have a good color, as did the ileum. The entire small intestine was palpated, and no other abnormalities of the intestine or its mesentery were noted. The postoperative course was uneventful except for a small wound abscess which developed but healed spontaneously. When x-rays of the upper gastrointestinal area were taken 28 days later, the distal duodenum and many jejunal loops were found to be dilated. Hyperperistalsis existed. A distal jejunal obstruction was diagnosed.

On May 11, a second laparotomy was performed. Numerous adhesions existed throughout the peritoneal cavity. Twelve inches (30 cm.) distal to the duodenojejunal flexure, an intussusception again was seen. There was a mass in the jejunal lumen. Six inches (15 cm.) of jejunum were resected and an end-to-end anastomosis performed. The resected jejunum was 4 in. (10 cm.) in diameter. One inch (2.5 cm.) from the proximal resected margin two polyps were found. There was a pedical measuring 1 cm. in length and 0.5 cm. in diameter. At the end of this there was a bulky mass of multiple polyps measuring 2 in. (5 cm.) in diameter. Three centimeters from the same resected margin another pedicle was found, 1 cm. long and 0.5 cm. in diameter, at the end of which was a group of polyps 4.5 cm. in diameter.

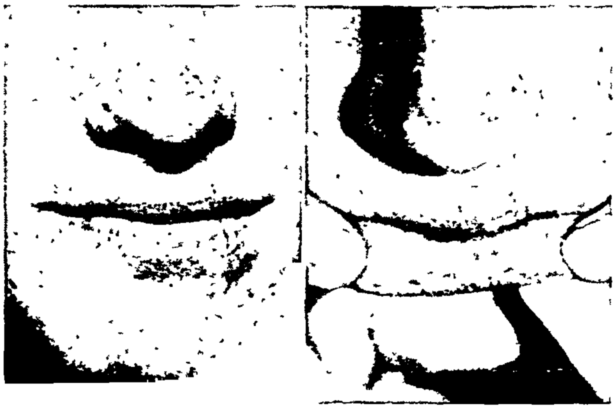
The microscopic sections showed adenomatous polyps with frank malignant degeneration located at their periphery. There was no invasion of the pedicle or muscularis of the intestine. There was a mass within the ileal lumen about 12 in. proximal to the ileocecal junction. Through an enterotomy, a polyp was removed. Microscopically, it was shown to be of the benign adenomatous type. The appendix was also removed. Postoperatively, a pelvic abscess developed which was incised and drained.

Though recovery was slow, no subsequent complications developed. On June 11, a sigmoidoscopic examination revealed three polyps in the colon at 5.5 in. (14 cm.). These were removed and microscopically found to be benign adenomatous polyps. Two air-contrast barium enemas were given in mid-June. A polyp was demonstrated in the proximal ascending colon. A series of x-rays of the upper gastrointestinal area were taken and a fractional study of the small intestine was made late in June. Though the jejunal loops were prominent, there were no intralumenal defects or obstruction.

On Sept. 21, this man was admitted to the U. S. Naval Hospital, Oakland, Calif. He was in good health and asymptomatic. The history, aside from that already given, was noncontributory. From the family history it was learned that the man's father had died "in his early 50's" from "an ulcer." His mother had died in 1947, at the age of 34, from a "tumor in her bowel." The patient did not know if she had had pigmentation of the lips or hands, and no other history was available. There were four other brothers, ages 24, 21, 19, and 17. All were living and well, and, to the best of the patient's knowledge, none had pigmentation on the lips, face, or hands or gastrointestinal complaints.

On physical examination, the patient was found to be a well-proportioned, slender, 6-ft. (182.9-cm.), 148-lb. (67.3-kg.), fair-skinned, blue-eyed individual. His hair was light brown. Over the vermillion border of the lips and extending into the labial mucous membranes there were numerous small (0.5 to 1.5 mm. in diameter), flat, pigmented spots which extended periorally (see figure). There were no pigmented spots on the hands or feet. There was a well-healed, broad, right rectus scar. Aside from these features, the examination was within the limits of normal.

The hemogram, urinalysis, Kahn test, stool examinations for occult blood while on a meat-free diet, and the roentgenogram of the chest showed results that were negative or within normal limits. There was no evidence of anemia. A sigmoidoscopic examination revealed a small polyp at 15 cm. which was removed by coagulation. The existence of a small polyp in the proximal ascending colon was again denoted by the use of a barium air-contrast enema. In the distal portion of the second part of the duodenum, viewed roentgenographically, two large radiolucent areas, thought to represent polyps, were seen. A fractional study of the remainder of the small intestine gave negative results.



Photograph of the lips. *Left*, pigmented spots extend into the immediate perioral region. *Right*, pigmented spots are seen on labial mucous membrane of everted lower lip.

On Oct. 27, a laparotomy was performed. When the duodenum was opened, eight polyps were seen. Two were approximately 1 cm. in diameter on long stalks measuring 2.5 cm. in length; one was sessile, 8 mm. in diameter and 4 mm. elevated. These were excised. Five additional small polyps, 1 to 3 mm. in diameter, were destroyed by electrocoagulation. The entire small intestine was palpated. Six inches (15 cm.) distal to the ligament of Treitz, the previous end-to-end anastomosis site was observed. Fifteen inches (42 cm.) distal, a polyp 2 cm. in diameter on a 5-cm. stalk and a second polyp 3 cm. in diameter on a 1-cm. stalk were found. In the ascending colon, 7.5 cm. distal to the cecum, a polyp 1.5 cm. in diameter on a 4-cm. stalk was noted. All of these were removed. The microscopic sections evidenced benign, adenomatous polyps of the duodenum, jejunum, and large intestine. Aside from a minor wound infection, the postoperative course was uneventful.

The most recent x-rays of the upper gastrointestinal area, fractional small intestine study, and barium enema with air contrast revealed no evidence of polyps.

Comment

This case exemplifies many of the features reported since the entity of intestinal polyposis was recognized by Peutz in 1921 and extensively reviewed by Jeghers and associates in 1949.[2a] The family histories reviewed by the latter revealed the hereditary aspect of this disease, a trait inherited as a Mendelian dominant. Numerous tabulated case reports have verified this fact.[1a] In the case presented, the death of the patient's mother at the age of 34 from "a tumor in her bowel" is suggestive evidence as to the source of the trait.

The dark complexion of most persons having this syndrome has been repeatedly mentioned.[3b] One of the patients reported on by Kitchin had a light complexion.[4] The patient discussed here was blue-eyed and of fair complexion.

The condition has been reported in persons from childhood to the sixth decade but usually appears as a recurrent intussusception in the second decade.[5] This 22-year-old man experienced recurrent attacks of pain culminating in surgical intervention, and an intussusception of the jejunum was discovered. The repeated bouts of abdominal discomfort, due to partial obstruction and intussusception, have been reported as characteristic.[6]

This patient believed that he had always had the small, flat, discrete pigmented spots on his lips. He had not observed their presence over the labial mucous membranes. The extent of pigmentation in this case is limited. Typically, the melanin spots are not only on the lips and labial mucous membranes but also the buccal mucosa, occasionally the gingiva and hard palate, and rarely on the tongue. The pigmented spots also occur on the digits, periorally, about the eyes, and, more rarely, across the bridge of the nose.[2a]

The patient in the case presented had polyps removed from the duodenum, jejunum, ileum, and ascending and sigmoid colon. The two removed from the jejunum showed malignant degeneration; the others were benign adenomatous polyps. Jeghers has pointed out that polyps may extend from the stomach to the rectum but their existence in the small intestine is a constant feature. Though malignant degeneration was observed by him, a recent review of collected cases revealed the incidence to be 15%. It has been emphasized that the polyps in this syndrome are to be considered premalignant lesions. Rectal bleeding and anemia, noted as additional complications,[7] were not present in this patient.

Excluding the drainage of the pelvic abscess, this man had undergone three abdominal operations. Multiple laparotomies in this syndrome are a common feature.[5] In the case reported by Stewart and Storey,[8] a total of nine surgical procedures had been performed. In another, reported by Jeghers, a sprue-like syndrome developed after portions of the small intestine were resected, and inanition and death ensued.[2a]

It is apparent in this case, despite careful and repeated examinations, that either lesions were overlooked or they developed with striking rapidity. The need for careful, frequent, regular, repeated examinations is imperative. At the time this article was accepted for publication, this was believed to be the 49th surgically proved case of intestinal polyposis with pigmentation of the lips.

Summary

A 22-year-old man had polyps of the duodenum, jejunum, ileum, and ascending and sigmoid colon associated with pigmented spots of the lips, labial mucosa and perioral region. The hereditary element was probably present. There were two occurrences of intussusception, and two of the polyps removed were malignant.

THE ROLE OF THE PSYCHIATRIST IN REHABILITATION

Francis J. Braceland, M.D., Sc.D., Hartford, Conn.

Much of the history of psychiatry is concerned with rehabilitation of a sort, for it has labored against tragic odds to restore emotionally crippled people to more adequate modes of life. The disciplines of rehabilitation and psychiatry both maintain that it is incumbent upon the therapeutic team to rehabilitate man as man, no matter how disabled he may be or how seriously restricted are his activities. It is important to treat the patient with the background of his environment in view, as well as in the light of the personal, interpersonal, and social meaning of his illness. Psychological reactions of patients to any type of illness depend largely on the previous personality make-up of the individual. The rehabilitation team, therefore, must be ever alert to any force which might impair motivation for recovery. The real problem of rehabilitation consists in helping the patient realize and accept that the emotional rewards of health are greater than any secondary gains derived from dependency ever can be.

t is indeed a pleasure for a psychiatrist to address audience dedicated to the principles and goals of abilitation. That much of the history of psychiatry olves around efforts at rehabilitation is evident in testimony of generations of psychiatrists who rked against tragic odds to restore emotionally ail- or crippled people to more adequate modes of ng. Those efforts involved only too often the use of y principles and imperfect instruments. But they tributed to the body of knowledge of the human d, the implications of which extend far beyond bounds of psychiatry. The insights of psychiatry of value to the field of rehabilitation, where the atest obstacle to the reablement of the physically ndicapped often resides in the emotions. Emotions d attitudes may be more incapacitating than the l disability, as Osler noted several decades ago en he warned doctors treating tuberculosis that at is in the patient's head is at least as important what is in his chest.

It is self-evident that psychiatry and rehabilitation ve much to teach each other. They deal with two of e greatest adversities that befall mankind—mental or ysical disaster, whether innate or acquired, acute or ronic, temporary or prolonged; and with ways and eans to lighten the burden upon individual and so- ety. They both work in the framework of the thera- utic environment and the therapeutic team and, us, in the context of group dynamics. Most impor- nt of all, they subscribe to the philosophy that what ey are dealing with is not a passive, amorphous be- g to be manipulated willy-nilly, but is an individual ho lives, feels, thinks, struggles, and expends his ergy in defending himself against a threat to his tegrity. Psychiatry and rehabilitation both maintain at it is incumbent upon the entire therapeutic team rehabilitate man as man, no matter how badly dis- led he may be or how seriously restricted in his tivities. I submit that we are striving to return to ciety a "compleat person," skilled and perhaps newly illed in important techniques and especially in the rt of living.

Any physical anomaly, however benign, and whether onstitutional or acquired, can be the source of seri- us disturbances in the life of an individual. A nose, he contour of which offends only the owner, may be s formidable an obstacle to adjustment as a major mputation. The problems of rehabilitation are, there- ore, extensive and extremely complex. They arise in he wake of accidents and crippling diseases and also with acute and chronic illnesses, and, very importantly, with the attrition of years. The rehabilitation of the aging individual is indeed one of the most meaningful fields of modern medicine. So is that rehabilitation which involves disabilities of insidious onset. By the time the disorder is clinically detected, it may have caused great physical depletion and profound psychological changes. The psychiatrist is deeply concerned with all these problems and his orientation is beginning to influence, if not reshape, contemporary medicine itself. Medicine is finding that to fulfill its obligations in a changing epidemiology and a changing culture, it is not enough to apply the insights and techniques of pure science. It is equally important to treat the patient against the background of his environment, and in the light of the personal, interpersonal, and social meaning of the illness. Illness represents a serious threat to the patient as a self-sufficient, intact individual, and hidden forces operating within him may have much to do with its course and outcome. These influences cannot be ignored in any treatment program for any illness or any handicap; they spell the difference between success and failure in our efforts and they are indeed basic materials with which to work.

Rehabilitation is rooted in contemporary medicine and contemporary public health services. It is one with curative and preventive processes and complements

---

Fifth Annual Dr. Fred H. Albee Memorial Lecture, read before the Kessler Institute for Rehabilitation, West Orange, N. J., Nov. 10, 1956.

and completes all of these. Rehabilitation may be as inclusive or as limited in meaning as the concept of the user. It may suggest an effort to make the best of grim adversity, even if this means adjustment at a lower level, or it may suggest a new and better integration. The former is easier to achieve, of course. But is it not our duty to make the goal a more positive one and refuse to settle for less than rendering the disabled individual as complete a person as it is possible for him to be, in a society which has room for people of all kinds and combinations of skill, capacity, and motivation? If this is our goal, we must be cognizant of psychodynamics, of the way in which the human personality is formed, and of the mental mechanisms and the defenses that determine behavior. Such knowledge enables us to work more purposefully in rehabilitation. It is the role of the psychiatrist in rehabilitation not only to treat patients who require his special skills but to serve as a consultant to the rehabilitation team and to clarify those influences which in general and in particular prolong convalescence and, indeed, make this a never ending phenomenon.

Psychological Hazards of Disablement

Unfortunately, there is no blueprint to be followed for dealing with or avoiding the psychological hazards of disablement. Each patient is unique, moulded by his past history, colored by his environment, imbued with goals and values as various as they are complex. But there are certain guides to understanding how and why the individual reacts to stress in a particular way and, if these are utilized early enough and consistently enough, the task of the rehabilitation team can be facilitated.

Let us examine briefly some of the psychological forces operative in physical disability. It was formerly believed that various disabilities brought a fairly consistent pattern of psychological reaction. The tuberculous patient was said to be euphoric; the deaf person inclined to paranoid behavior; the one whose disease was located below the diaphragm vulnerable to depression. It is now recognized that the psychological reactions of patients to any type of illness depend largely on their previous personality make-up. The same is true of reactions to trauma. Some individuals recover quickly; a few develop serious emotional difficulties; and there is a wide range of reactions between both these extremes. The degree of emotional disturbance is by no means directly related to the intensity of the trauma; you have experiences of this kind every day. It is related, however, to the meaning of the trauma to the person concerned. There may well be patterns of defeat in the personalities of patients which delay physical reablement and social readjustment for a long period, and even indefinitely.

Human motivation is a curious process, for it is based on unconscious, as well as conscious, needs. It is therefore not a simple thing to motivate a patient to work toward his own recovery, although certainly an atmosphere of optimism and high morale t therapeutic team helps enormously. The situat complicated, however, by basic human needs: r for love and attention, dependency strivings and s gles against them, feelings of hostility, and feeli guilt. These patterns are found in the developme every individual and difficulties arise when they been imperfectly resolved in the course of matur Sudden physical disaster and, even more insi physical attrition, reactivates conflicts, threats anxieties of long ago. There may well be a retre a more comfortable antecedent state contrived e in life to minimize anxiety and pain. The adverse p chological impact of disablement is in fact gre enhanced when it actually or symbolically recap lates conflicts of childhood. The individual tends revert to immature methods of handling them and rehabilitation problems are compounded.

The rehabilitation team should be alert to th forces which impair motivation. The disabled indiv ual may equate service from others with love a attention previously denied him. He may equate with punishment of those who neglected him in t past. He may equate the helplessness it symbol with retribution for his own hostility and guilt. J as the victim of sudden disablement must work thro the inevitable depression he feels, so he must w through his dependency needs before he can go on better things. In some instances a certain degree dependency will be inescapable; the patient cannot entirely self-sufficient and he must be encouraged accept this. He must also be encouraged, however develop new skills and interests. The real problem rehabilitation consists in helping the patient re and accept that the emotional rewards of fuller fu tion are greater than any secondary gains deri from dependency. Here is the watchword; if you do this, your work is a success, no matter what you accomplish.

Throughout the period of convalescence, depe ency problems will present themselves again again. Even patients who are making excellent p ress will have occasional lapses in that direction questing help or assistance in tasks they have alre mastered. Such patients need support and reassura so that they can go on to learn new tasks. As diffi as the overtly dependent patient, and sometimes m so, is the patient who denies his disability and de his dependency needs entirely. An unrealistic ins ence on independence and self-sufficiency also le to defeat. Underlying it may be a real need for s port and a need to be punished for it. As Menning has noted in this connection, for these patients a p gram of graduated activities within their capabilit is of great importance. This will help shield them fro the mistakes they will make and the humiliation the will suffer if they are allowed to proceed as parago of courage, if not of prudence.

Accepting a Handicap

So it is that the permanently disabled patient must ther surrender to his handicap nor deny that it ex- s. Accepting the disabled self is the decisive step the road to rehabilitation. The difficulties of ac- pting this new self should not be minimized, how- er. There is a body image involved in it that sub- nds the individual's conception of his own person- ty and his relations with others. The image has been ilt up from infancy and it contains many irrational d symbolic associations from infancy and childhood. ese associations linger in the deeper recesses of the nd; they contribute to exaggerated emotional re- tion to injury or loss of parts of the body, to exces- e fear or depression with minor disabilities to imma- re childish behavior that blocks rehabilitation.

Hence, in addition to making an adjustment to rtain real limitations and adaptations imposed by e disability, the patient must work through to a re- sion of his body image, his conception of himself, d his relations to others. This is a process which ay well rekindle old conflicts and painful associa- ons, so that the individual reverts for a time to im- ature patterns of behavior. That it is a natural proc- s and one that should be accepted sympathetically v the rehabilitation worker is self-evident. The prob- m is to work with the more mature aspects of the ersonality to prevent any chance of chronic regres- on and to support the patient through the crisis.

In general, the more immature the individual, the ore pathological his reaction to physical disability. rustrations imposed by it can be inordinately stress- ul, even in the face of excellent remedial and rehabil- ative measures. Particularly in the early stages of isablement, when the extent of the residual handi- ap cannot be estimated, it is important to foster the proper psychological climate. Uncertainty of the out- ome may foster vague but distressing anxiety, and his may continue long after the situation has been larified and after the prognosis has been found to be etter than expected.

Generalized anxiety has a blocking effect on reha- bilitation efforts. This is true whether it comes from he patient's insecurity and uncertainty over his fate, rom the symbolic significance of his condition, or rom unconscious motivations which bring him under he yoke of the secondary gain of symptoms. A chronic disability may weaken personality integration because of the anxiety it constantly evokes. As a result, the patient may confuse functions which are actually impaired with those which are not. The same aspects of disability which interfere with mastery of physical environment may impair social behavior. Impaired locomotion, or an impaired sense organ, may force a change in social relationships. The ensuing frustrations can be reduced by prostheses and the development of new skills. But much depends on the patient's own orientation and his will to keep trying in the face of initial difficulties and failures. Establishing satisfactory relations with other people is of tremendous importance, though it depends on the attitudes and responses of these others, as well as on those of the patient. Here the need of fostering wholesome family attitudes and responses cannot be over-emphasized.

In all treatment situations various emotional reactions are set in motion within the patient and in those who are handling him. These reactions may be psychonoxious instead of psychotherapeutic. When difficulties arise which seem to threaten the progress of the rehabilitation effort, the patient is usually blamed for it. The blame is not always his; it sometimes accrues to the person who is trying to help him. Psychiatrists recognize this development in therapy; they recognize their own contribution to it and allow for it. It need not be viewed as a threat to the therapist or the patient. It simply calls for understanding examination. This is one of the earliest and most useful lessons the young psychiatrist has to learn—the effects of his own attitudes in a given situation. It has been noted many times that patients are aware of the attitudes of the staff, even though these are neither verbalized nor otherwise openly expressed; that patients look for social acceptance and are alert to signs of rejection; that to patients the attitudes of the staff represent a cross section of attitudes of the larger world toward them. Their reactions to staff attitudes are expressed in positive or negative attitudes to the workers in the center. These reactions vary from dependence and affection to hostility and negativism. In these situations again, psychiatry has something to offer through the medium of staff conferences.

Role of Rehabilitation Worker

It is unwise for the rehabilitation worker unskilled in psychiatric techniques to undertake meddlesome psychotherapy in a potentially explosive situation. At such a time expert advice is imperative. We have, in psychiatry, a very troublesome group of problems falling into the classification of traumatic neuroses and having their onset after acute physical or psychic injury. Sometimes there is a considerable lapse of time before the neurotic symptoms appear. In any event, they are usually altogether out of proportion to the severity of the trauma. Elements of secondary gain are readily seen and, depending on predisposition, a psychopathological picture of a specific kind may well appear. An essential principle in the treatment of these cases is prompt institution of psychotherapy, for prognosis worsens with the passage of time. This is particularly so in cases in which compensation may be forthcoming. Laughlin [2] has written some illuminating pages on this problem. He states, in effect, that what the individual craves is not only the material compensation but also the satisfaction of strong, deeply hidden, dependency needs and the abrogation of responsibility. Delayed treatment enables the industrial accident case, for example, to become a chronic problem. Yet, from the outset the patient balks at treatment. What he achieves from a lower level of adjustment seems to be worth far more to him symbolically than the greater financial and personal reward that independence could supply. He is, therefore, loath to accept psychiatric treatment, persists in trying to prove his disability, and is affronted by the idea that psychological factors are contributing to his disability. Even if he agrees to try psychotherapy, his resistances continue. An expert therapist is needed to deal with these resistances and help the patient resolve them. Conflicts must be recognized and faced by the patient despite the anxiety and discomfort temporarily released. Recovery depends on the acceptance of the conflicts, on ensuing processes of desensitization, and on the overcoming of irrational nonrealistic elements.

There are, however, many other situations in which the well-trained rehabilitation worker, skilled in interpersonal relations and abreast of the psychology of disability, can do excellent work. Basic to his effort is a principle laid down in the aforementioned work of Menninger[1] that the disability is not so much what the examiner perceives it to be, as it is what the patient perceives it to be. The rehabilitation worker can discover this dynamic element only by getting to know the patient, by talking to him and listening to his problems, and by determining what the goals and values of the patient have been and whether these must now be altered. The physically disabled person tends to find that some psychological maneuvers, useful in the past, are now no longer so. He may have been satisfied formerly when running up against a difficult situation to beat a reluctant retreat; or he may have found it easy to lower his level of aspiration when certain goals were apparently impossible of attainment. This is not a good philosophy in all matters. Objectives, while they may have to be changed, are nonetheless essential. The handicapped person needs to strive persistently for goals which are attainable if he works hard enough; and he needs to try out many ways of reaching them instead of just one. The rehabilitation worker has a vital role to play during this phase of the program. Not that he should set the patient's goals; but he should help the patient set his own goals, goals within his remaining capacities, and goals which once set should then be accepted and reached. Persistence and variability in approach are essential. So is the cultivation of efficient habits while strong motivation exists.

General principles of learning yield valuable insights and suggestions for rehabilitation. So do techniques and procedures of psychotherapy, which can create favorable conditions for learning new and successful adjustments to disability. It is important at all times to look upon the handicapped person as a normal person with extra difficulties and to ge to see himself in this light. It is a common observ that undesirable trends may assert themselves in personality of the handicapped as a result of medical tags they bear. All branches of med show an unfortunate preoccupation with symp and labeling and with attempts to equate diag and treatment. Menninger has emphasized this pa ularly for psychiatry, but his observation is gen to what we are talking about here:

"To say that a patient has schizophrenia is both scientific and improper; unscientific because we being precise about something that is highly a phous, improper because we are damning the pat with a title that will hurt him forever."[3]

Even in other areas it is certainly true, as Men ger pointed out, that to say a patient has such such a disease often bears no logical relationshi what ails the patient and how he should be trea Labeling of this kind, though it appears scientific necessary, carries with it the danger that we may to treat the disease instead of the patient. Let us forget that the epileptic, the athetoid, the amputee find it difficult to conceive of himself as an epile an athetoid, an amputee and as a human being– the same distorted image.

There is a place for inspiration, too, in the reh tation of the disabled. The patient needs encou ment in his difficult task of regaining lost functio developing new ones. The power of mind over for the relief of symptoms has always been recogn All treatment was once a form of mental thera faith healing. The medicine man, with his extra nary costume, his impressive paraphernalia, an ritualistic behavior, tried to cultivate an atmos of hopefulness for recovery. His successes, and were many, were attested to by awed and gr patients. As for his failures, also many, let us say Haggard[4] that "the dead give no testimonials." point is this, however: that creating a therapeut mate is proper to the art and science of med From the statements of disabled patients, it is that simple and fundamental, unorganized, and naïve psychotherapy often inspires them to search work for a more normal way of life. During the observers noted two influences which, when oper on the personalities of men, were of the greates portance in preventing neuroses and chronic disab These influences were high individual motivation high group morale. Men who were strongly motiv or who were sustained by the morale of the g overcame fears and difficulties quickly, for they let neither themselves nor their colleagues down. S ly a vital aspect of the work of rehabilitation per nel is to promote these influences which not only vate and move patients so profoundly but also rescue them from the dread isolation which se weigh upon them, from the apathy often imposed serious personal loss, and from the hopelessness ich shrouds the future.

Spirit of Rehabilitation Team

submit that inspirational programs are acceptable l necessary. However, to inspire a person to high tivation it is necessary to believe in one's program l to be convinced of the importance of one's task. e team spirit is of great importance; it is born of close collaboration of all members of the team o form a competent, homogeneous unit, and give themselves freely to the common task. Patients are remely sensitive to the spirit of the team, and they adversely affected if that spirit is evanescent. Work progress in mental hospitals demonstrates persua- ely the great importance of interpersonal influences the management of patients.[5] From many points view a rehabilitation center, like a mental hospital, an interacting system in which the activities and at- udes of each participant affect those of all. It has en found that an excellent association between a pa- nt and a physiotherapist may act as a stimulant to otivation when all other methods seem to fail. It s been found that a careless remark by a physician ay throw a patient who has been making good prog- ss into anxiety or depression.[6] Such accidental occur- nces can be highly noxious to the entire rehabilita- on team as well.

High group morale should indeed be the watch- ord of every treatment group. If it is lacking, the habilitation center is in danger of becoming a ware- ouse for expensive gadgets and work-a-day attitudes. morale is high, it will spark the will to live and become proficient in living, no matter what the andicap. The response will be more than rewarding the devoted team of workers who create an atmos- here for recovery. It is the physician who must set ne example for his team and for his patient. The phy- cian is certainly the most powerful force in the re- abilitative process outside of the patient. He is to the atient not only a doctor of medicine, possessed of ast knowledge and great technical skills, but a figure f authority reaching the dimensions of omnipotence. he cast he assumes depends on the patient's depend- ncy needs and his quest for parental figures. The hysician must be alert to this imposed role, for it nay retard the restoration of the patient. He must be ure that the doctor-patient relationship remains on a herapeutic level, in accord with realities of the situa- ion, rather than with magical thinking that so easily asserts itself in the mind of man.

The psychological problems of rehabilitation are so many and so diversified that the psychiatrist cannot and should not arrogate to himself more than a small portion of them. The major job must be done by the rehabilitation team. There are other key groups in the community which can make a contribution in preventive psychiatry; the general physician in his work with families; specialists in their treatment of the patient; nurses who care for the patient in the early days of disaster. What each of these tells and does to the patient can affect his motivation and his future. All such groups need a basic psychiatric orientation to be used on a conscious basis. It has been pointed out, quite correctly, that using this psychiatric orientation haphazardly or unconsciously is much less effective than basing it on a lucid awareness of the psychological forces which usually operate in the newly disabled individual.[7] Although emotional first aid may be necessary and emotional support is required, it is well to remember that the patient usually has within himself the restorative potentialities needed and that naïve interference may complicate the healing process. Further than this, too rapid removal of the emotional symptoms may jeopardize the outcome. All those who deal with disabled patients should understand such basic principles and keep within their area of competency, lest they aggravate the emotional difficulties that invariably arise for a time at least.

The psychiatrist is but one of the team of specialists and auxiliary workers active in the rehabilitation field. Although he must assume important diagnostic and therapeutic functions in the more difficult and complex cases, his role is predominantly advisory and educational. His contribution should grow with advances in his specialty, particularly in the area of social psychiatry as it opens up new possibilities for treatment and prevention. The task imposed upon those of us who are privileged to treat our fellow man is as unending as is the search for wisdom. Every insight we attain reveals the existence of more questions to be answered, more mysteries to be revealed. Reality, including man's own, is inexhaustible. So, too, are the uses of adversity. Let us be prepared to make these our servants, not our masters.

RESIDUAL DISABILITY OF PHARYNGEAL AREA RESULTING FROM POLIOMYELITIS

CLINICAL MANAGEMENT OF PATIENTS

James F. Bosma, M.D., Salt Lake City

Despite the earlier clinical impression of relatively good motor recovery from bulbar poliomyelitis, if the patient has survived,[1] there is a progressive accumulation of patients having clinically significant residual disability in the pharyngeal area following this disease. A group of 33 child and adult patients having poliomyelitic disability of the pharynx has been observed by standardized clinical and roentgenographic procedures and is the subject of additional clinical reports.[2] The motor disabilities of the pharynx of these patients result from a marked variety of particular muscle weaknesses and, also, are variably combined with residual impairments of respiration or of general motor function of trunk and extremities.

The physician responsible for the continued care of these patients having continued disability in the pharynx is concerned with particular handicaps of performance and their relief or amelioration. Accordingly, the following clinically useful classification of impairments of the mouth-pharynx area has been devised.

The most commonly identified poliomyelitis paralysis in the area of the pharynx is that of the constrictor musculature. More and more patients have clinically significant residual disability in the pharyngeal area following this disease. The motor disabilities of the pharynx of these patients result from a marked variety of particular muscle weaknesses. Understanding the motor performance and disabilities in the pharynx depends upon recognition of the role of the tongue-hyoid-larynx column. The optimal time of initiation of efforts of motor rehabilitation is soon after the acute phase, as soon as cooperation of the patient can be achieved.

Classification of Motor Disabilities

Deficiencies of General Motion of the Tongue-Hyoid-Larynx Column.—Understanding of motor performance and disabilities in the pharynx depends upon recognition of the role of the tongue-hyoid-larynx column. In the human, the muscles suspending the pharynx, larynx, and the posterior portion of the tongue converge upon this articulated structure (fig. 1 and 2), whose general motions are essential to usual manner of performance of swallowing, and are normally involved in speech. The valvular mechanisms of the pharynx and larynx are integrally related to the general motions of this column in relation to the cervical spine and posterior skeleton of the face. Thus, the support of the bolus in the swallow-preparatory position within the mouth and its controlled conveyance into the pharynx, the apposition of the palatopharyngeal folds to prevent penetration of the bolus into the epipharynx, the closure of the larynx, and the opening of the hypopharyngeal sphincter are all essentially associated with the general motions of the tongue-hyoid-larynx column accomplished by its suspensory musculature. This vertical motion is greater in the older child and adult than in the infant, in correlation with the descent of the pharynx and related structures, in developmental elongation of the neck. Some clue to deficiency of strength of elevation of the tongue-hyoid-larynx column is provided by observation of the exceptionally depend position of this column and the associated structu of the pharynx in lateral or posteroanterior roentge grams; the latter projection may also demonstrat lateralward displacement of the radiopaque-medi outlined valleculae and floor of the hypopharyn well as a possible angulation of these structures f the transverse plane.[2d] The significance of the gen elevation of this column for the swallowing perfo ance is well demonstrated in circumstances of r tive deficiency of its elevating musculature. A st ard clinical maneuver for evaluation of strengt this elevation is that of clasping the column with examiner's thumb and first finger approximated the notch between hyoid bone and thyroid cartil and exerting traction downward. In subjects hav normal strength of its elevation, the column is ruptly lifted from between the clasping fingers. B in those having weakness of the suspensory muscu ture, the column remains in a relatively depend position. The swallowing effort associated with t impaired elevation fails. This failure may be gener with retention of the bolus in the pharynx and i spill upward through the palatopharyngeal isthm and also into the larynx, or the pattern of swall disability may differentially demonstrate deficien of approximation of the palatopharyngeal folds c failure of opening of the hypopharyngeal sphinct possibly with secondary spill through a persistent patent larynx. The extent and performance adequac of motions of the tongue-hyoid-larynx column in swa lowing can be evaluated by roentgen fluoroscopy. B

Chairman, Department of Pediatrics, College of Medicine, University of Utah.

reason of the multiplicity and complexity of these motions, they are more satisfactorily studied by timed film exposures or cinefluorography. Standardization of the subjects' position during roentgenographic studies of motion is important, as the relative extent of motions of these structures upward and anteriorward differs with the subjects' position; there is more anteriorward (ventrad) motion if the subject is in supine rather than in vertical position. In some patients having deficiency of strength of elevation of the tongue-hyoid-larynx column, there is an interesting disproportionate anteriorward motion of this column with the patient in upright position in apparent compensation for the deficiency of its upward motion (fig. 3*a*).

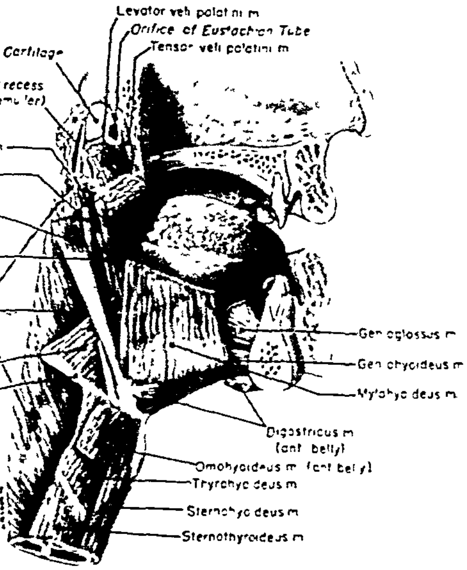

Fig. 1.—Lateral wall of pharynx from lateral aspect. Tubal cartilage and auditory canal are transected. Note suspensory arrangement of styloid, palatal, submental, and digastric muscles.

Impairment of Control of Delivery of Food into the Pharynx.—In the clinical circumstance of deficient support of the tongue and hyoid by its suspensory musculature, the "sizing" and conveyance of bolus to the swallow-preparatory position[3] by a temporally separate maneuver into the mesopharynx may be impaired or accomplished only by unusual adaptive motions of the tongue. In the circumstance of poliomyelitic impairment of the tongue and the irregularly distributed atrophy which is typically associated with it, these swallow-preparatory maneuvers are typically severely impaired.

If there is marked disability of tongue support or of the tongue itself, the patient may engage in a characteristic series of posture adaptations wherein the head is anteflexed during mastication so that the food remains in the anterior portion of the mouth and swallowing is initiated by abrupt upward tilt of the head, decanting the food as an unquantified mass into the pharynx (fig. 4*b*). Characteristically, the patient with deficient control of the oropharyngeal orifice avoids eating in any but the upright position to diminish the risk of premature spill of food into the pharynx. The mechanism and adequacy of motor control of the oropharyngeal orifice are best evaluated by means of lateral roentgenograms of the subject in supine position with bolus in mouth. These are particularly useful in evaluating the defense of the pharynx against premature entry of food from the mouth.

Abnormal Patency of the Palatopharyngeal Isthmus.—Incident to swallowing, the palate demonstrates three consecutive actions: (1) an approximation to the elevated tongue by which the bolus is held in preparatory position (fig. 3*a*), (2) an enclosing action of the palatopharyngeal folds during conveyance of the bolus into mesopharynx, and (3) angulation upward away from the tongue, in correlation with the final elevation of the pharynx, as the bolus penetrates the hypopharyngeal sphincter (fig. 3*b*). Roentgenographic evaluation of prevention of ascent of the bolus in the palatopharyngeal isthmus and potential "nasal regurgitation" must be made during the phase of conveyance of the bolus between the tongue and the combined palate and palatopharyngeal folds into the pharynx (action 2, as noted above). The final position of the palate in swallowing gives little clue to its contribution to containing of the bolus.

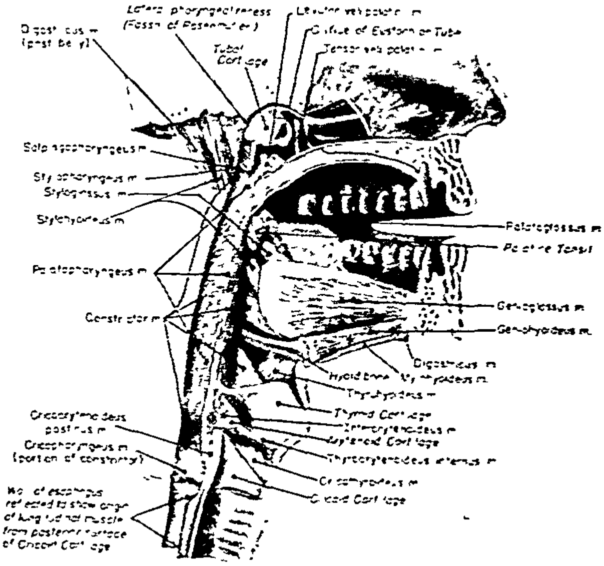

Fig. 2.—Lateral wall of pharynx from medial aspect. Tip of tubal cartilage is excised to show origin of salpingopharyngeus from inferior aspect of cartilage.

There is surprisingly incomplete correlation between visually observed abnormalities of motion of the palate and the palatopharyngeal folds during phonation and their adequacy in preventing penetration of the bolus through the palatopharyngeal isthmus. Thus, a unilateral weakness of the palatopharyngeus may be associated with an adequate function of the palate and palatopharyngeal folds in swallow as result of compensation by the contralateral palatopharyngeus or by the sphincter action of the pharyngeal constrictor muscle.

Obstruction at the Hypopharyngeal Sphincter.—The motor mechanism of the opening of the hypopharyngeal sphincter in the normal subject is not completely understood. It is apparent that, in usual modes of swallowing, elevation of the larynx is essential but elevation of the lateral pharyngeal walls is not essential to this part of the swallowing performance. Upon the basis of roentgenographic observations in patients demonstrating various patterns of postpoliomyelitic disability of the hypopharynx,[2a] it has been inferred that the cricopharyngeus muscle contributes an essential vertical traction upon the sphincter.

An additional sphincteric arrangement in this area is that of the upper rim of circular fibers of the esophagus. In the swallowing action of normal subjects and of those poliomyelitis patients who have no obstruction at the hypopharyngeal sphincter, the sphincter typically opens to its broadest diameter immediately and continually, and there is no clue to a separate mechanism or circumstance of closure by the esophageal musculature. In one of the poliomyelitis patients with continued partial obstruction at the sphincter, there was noted an intrusion into the sphincter area from the posterior wall resembling that described by Brunner.[4] In another, there was a gross exaggeration of the rounded eminence of the cricoid cartilage and associated muscles protruding posteriorward into the hypopharynx and sphincter area.

Fig. 3.—Bolus in hypopharynx and esophagus. Lateral roentgenogram (*a*) of normal swallowing process in adult subject showing opaque bolus in preparatory position. Palate is pressed downward and forward to approximate tongue closing the retro-oral portal. Palate is lifted high (*b*), still in juxtaposition with tongue, which is elevated and extended to posterior pharyngeal wall. Hyoid (at square) is at its maximal displacement upward and ventrally.

In the absence of a consistently identifiable p- lytic disability found in association with persist occlusion of swallowing at the hypopharyngeal sph- ter, a variety of alternative explanations must be c sidered. A possible explanation is that of contract hypertrophy, or fibrosis of the cricopharyngeus adjacent circular esophageal musculature. Strong e dence against this possibility is the normal em stream which these patients typically demonstr Also, extensive dilatation of the sphincter area h not achieved significant relief of swallowing disabil in two of the patients in this study. Kaplan[5] has r ported abrupt relief of total dysphagia, as a seq of poliomyelitis, in one patient immediately after v tical incision of the cricopharyngeus muscle; the prob lems of evaluation of improvement as result of ther peutic procedure in this clinical circumstance hav been discussed elsewhere.[2a]

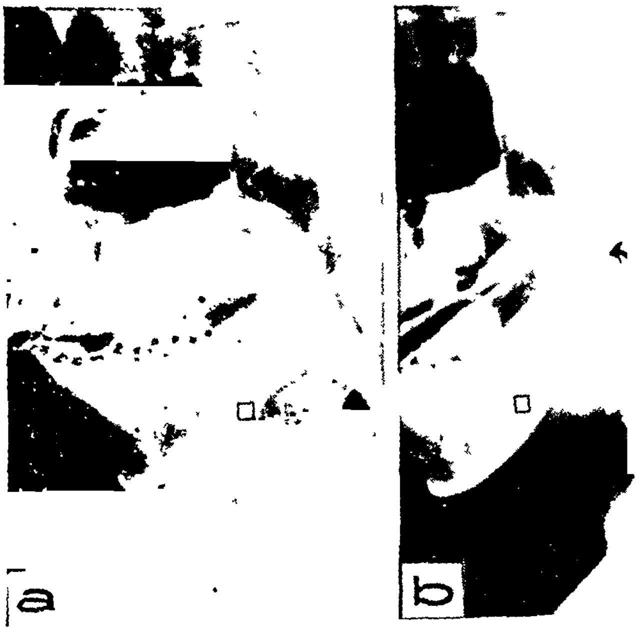

Fig. 4.—Abnormalities in swallowing in 8-year-old boy months after acute poliomyelitis. Lateral view (*a*) of bolus d canted from mouth into pharynx. Marked and irregular dimi tion in mass of tongue is shown by irregular contour (at ser of dots) of inferior border of bolus in mouth. Weakness a diminution of mass of tongue are shown further by irregu lingual border of portion of bolus in mesopharynx. Later st of swallowing (*b*). Mass of medium is retained in pocket atrophy of tongue. Hyoid (at square) is now moved cephal and ventrad, posterior wall of mesopharynx and hypophar is moved ventrad, and hypopharyngeal sphincter is widely op Palate, which at this stage of swallow is normally elevated this patient remains lax and pendant, reflecting weakne levator veli palatini. Incident to constriction of pharynx, t is regurgitation of bolus upward in palatopharyngeal isth (at arrow), despite open hypopharyngeal sphincter.

The varieties of systemic entities associated pote tially with inflammation and fibrosis of the muscul ture in the area of the sphincter, such as scleroderm with involvement of the esophagus,[6] myoporphyria and paroxysmal hemoglobinuria,[8] have been consid ered and differentially excluded in these patients Likewise, the Plummer-Vinson syndrome, more re cently termed "sideropenic dysphagia,"[9] has bee luded. The separate possibility of swallow-inhibi- y influences from the mucosa of the hypopharynx ronically inflamed, in association with stasis of retions, or of inhibitory afferent influences from adjacent esophagus have also been considered, t this disability has persisted in the face of repeti- e and prolonged cocainization of the mucosa in th areas. A further possible explanation of failure opening of the hypopharyngeal sphincter is that coordinative impairment, by which the extraor- narily consistent pattern of sequential activation of e musculature in the pharynx area accomplishing allowing [10] is interrupted as a result of encephalitic sions disseminated within the reticular substance the brain stem.

A coordinative disability of the larynx has been entified incident to studies of speech pathology in ese patients in whom function has been impaired poliomyelitis.[11] In studies to date, it has not been ossible to distinguish objectively the automatic and niform coordination of reflex swallow so that it could e identified in clinical work in comparison with ap- arent valid effects or simulations of swallowing hich the subjects may employ while under study r their disability. A possible other explanation is at of a "functional" disability of swallowing which ay be continued as an anatomically and physiologi- ally inappropriate persistence of an "organic" failure f swallowing. The distinctive affective reaction and djustment of persons long deprived of this important nction is of much significance in their continued isability.[2d]

Abnormal Penetration of the Larynx.—By embryonal erivation and association of coordination, the aryte- oid apparatus controlling the laryngeal aditus is ntegrally related to the musculature of the pharynx. he precise mechanism of relation of the typically ssociated closure of the aditus and opening of the ypopharyngeal sphincter is not yet entirely clear. nfortunately, for purposes of this study, it was diffi- ult to evaluate motion in the arytenoid area roent- enographically, by reason of incomplete calcification f the arytenoid cartilages in the majority of our sub- ects and, also, by reason of superimposition in lateral oentgenograms of the radiopaque medium outlining he lateral pharyngeal recesses. This was particularly he case in those patients in whom the lateral pharyn- geal recesses were paralytically enlarged and expand- ed anteriorward at the sides of the larynx. The lateral roentgenograms did demonstrate obliteration of the laryngeal vestibule late in the pharyngeal stage of swallowing as the bolus was penetrating the hypopharynx and sphincter. In some normal subjects this obliteration was incomplete, and, thus, it was more difficult to specify abnormality in those poliomyelitic patients in whom this final stage of elevation and approximation within the tongue-hyoid-larynx column was paralytically impaired. Penetration of fractions of bolus into and through the larynx typically occurred secondarily as an overflow from the hypopharyngeal pool. In a few patients having persistent occlusion at the sphincter and accumulation of a considerable hypopharyngeal pool incident to demonstration of swallow efforts, the arytenoid apparatus was apparently normally successful in closing the laryngeal aditus.

Weakness of the Constrictor Musculature of the Pharynx.—The most commonly identified poliomyelitic paralysis in the area of the pharynx was that of the constrictor musculature. This varied in degree and pattern of distribution and in associated evidence of performance disability. In the circumstance of asymmetrical weakness, there was a striking traction of the weaker pharynx wall toward the stronger side, which apparently resulted in diminution of the laxity on the paralyzed side, in partial compensation for the weakness. The possible contribution of the constrictor muscle to apposition of the palatopharyngeal folds and its compensatory role in association with unilateral weakness of the palatopharyngeus have been mentioned above. It is apparent that in the circumstance of weakness of the constrictor muscle at this level, abnormal patency of the dorsal portion of the food channel will occur.

Correspondingly, the contribution of the constrictor muscle to closure at the upper rim of the palatopharyngeal isthmus in the modulation of speech is probably critical and, in the circumstance of deficiency of constriction at this level, there may be an abnormal nasality of certain elements of phonation despite visibly and roentgenographically normal motions of the palate in these phonation maneuvers.

Unilateral or bilateral weakness of the constrictor of the hypopharynx results in significant performance disability, for portions of bolus may be trapped in the expanded and dependent lateral pharyngeal recesses. In the circumstance of incomplete swallowing, successive efforts may be required to clear the pharynx. In some patients, it is apparent that this further exertion is an important factor in fatigue limitation of swallowing at mealtimes. Incidentally, there is commonly a persisting hypopharyngeal pool in these subjects, causing a "bubbling" distortion of voice.

Compression of Pharynx by Malposition of Head and Neck.—A distinctive mechanism of pharyngeal disability in patients having extensive cervical segmental impairment in poliomyelitis is that resulting from severe lordosis of the cervical spine and anteflexion at the craniovertebral articulation so that the pharynx is compressed and occluded between the spine and the posterior structures of the face. This mechanism has been studied by Merritt and associates,[2e] who demonstrated that the occlusion of the pharynx could be relieved by traction and external support apparatus applied to the head.

In general, the spatial relations of head and neck are of considerable importance in performance of the partially impaired pharynx. In the position of extension at the head, for instance, the elevation of the tongue-hyoid-larynx column relative to the posterior skeleton of the face may be insufficient and the swallow thus fail, apparently by a mechanism analogous to that of downward traction upon the column by the clasped fingers of the examiner described above as a clinical evaluation maneuver.

Mechanisms of Exaggeration of Disability

The motor disabilities of the pharynx and related structures were found to be the resultant of a variety of factors in addition to specific poliomyelitic weaknesses and contracture and atrophy of the participating musculature. The additional mechanisms which may be superimposed to exaggerate the disability are classified below.

Nutritional Deficiency.—Acute poliomyelitis is commonly prolonged and prostrating, and alimentation is resumed in the face of a considerable nutritional deficiency. The passage of a naso-oral catheter may occasion much distress and resistance on the part of the patient, and adequate nutritional restitution may thus be delayed. Recovery of adequate swallowing occurs at various times in convalescence from severe bulbar poliomyelitis, and a natural tendency of physicians is to delay gavage feeding or performance of gastrostomy in anticipation of this achievement. Meanwhile, the patient's general motor recovery may be progressively retarded by nutritional failure.

Stasis of Secretions.—The normal performance of the pharynx is effective not only in initiation of alimentation and in modulation of respiration but also in facilitation of movement of secretions from middle ear, eustachian tube, and nasal cavity into the pharynx, from whence they are conveyed with the bolus. The "milking" action of the paired levérator muscles upon the eustachian tubes incident to their contraction in elevation of the palate is familiar.[2a] Negus [12] describes an analogous progressive constriction of the palatopharyngeal isthmus facilitating expression downward of the secretions accumulated in the nose and upper pharynx. The most critical and striking area of stasis of secretions is that of the hypopharynx, which, in patients having persistent occlusion of the hypopharyngeal sphincter, is typically the site of a chronic inflammatory reaction. This has been demonstrated by indirect visualization and also by a distinct tenderness in this area as explored by olive-tipped probes.[2d]

Intercurrent and Chronic Infections.—These patients experience a considerable exacerbation of disability at times of acute illness, so that a barely adequate swallow may be temporarily lost, or the larynx may be less capable of defending the tracheobronchial tree from penetrating bolus. By unfortunate coincidence, their acute respiratory illnesses are liable to become complicated and prolonged. Appropriate to the mechanical limitations of mobilizations of secretions, there is a greater liability to local exacerbation of an infective process such as otitis media, mastoiditis, or paranasal sinusitis.

An additional mechanism of sustained infec which must be considered but cannot be separ evaluated is the chronic tracheobronchitis which s of these patients have, with or without contin tracheotomy, in sustaining or aggravating contin infection and inflammatory reaction in areas of t nose, pharynx, and mouth.

Liability to Exaggeration of Disability by Fatigu The mechanical disabilities of swallowing and spe resulting from acute bulbar poliomyelitis often r quire extraordinary exertion for a particular p formance. Also, repetition of the effort is commo required, as in conveyance of bolus through t hypopharyngeal sphincter. The musculature c cerned in this effort is already weakened by pol myelitis. We thus have an accumulation of fact predisposing to accumulation or exaggeration of t disability of swallowing or speech in these subjec It is the factor of fatigue which causes prolongati of mealtimes or, in some subjects, a modified schedu of frequent small and briefer feedings.

Psychological Response to Disability.—The psych logical impact of acute severe bulbar poliomyeliti perpetuated and compounded by continuing disab ties. There may be an exceptional head-neck relat which the subject assumes continually or at ti of eating or of speech in compensation for disabi of the mouth or the pharynx. It may be necessar expectorate secretions frequently, and, in some pa tients having severe associated disability of the tong and lip, there may be frequent and profuse sialorrhe Food is often taken tediously, perhaps with freque expectoration of a portion of the diet. The individual social adaptation may be impeded by distortions o speech, such as marked nasality or associated di ability of articulation.[11] These multiple factors ma accumulate to cause a progressive social withdraw of the patient and restriction to a narrow range o familiar associates. Recovery of performance in th bulbar area may reach an inappropriate plateau the result of reluctance to attempt further achiev ments. This social withdrawal of the individual an lack of further rehabilitation goals at times prove serious handicap to the therapeutic team, to whic a patient may be brought late in this accumulatio of handicapping mechanisms.

General Principles of Rehabilitation

It is apparent that the patient having moderate o severe motor disability in the pharyngeal area following bulbar poliomyelitis presents a unique composit of clinical problems which are often inextricabl intertwined. Evaluation of therapeutic measures applied to particular primary or secondary aspects o disability is difficult. Rather, it is to be recognized that the goal of general improvement of function is the result of multiphasic efforts of medical maintenance and particular specialized therapies. Quite appropriately, varied routines or combinations of therap ve effective in this circumstance. Conversely, thera-utic efforts seemingly appropriate to particular tor impairments are found to be ineffective.

The optimal time of initiation of efforts of motor abilitation is soon after the acute phase, as soon cooperation of the patient can be achieved. Initial orts probably should be directed only to familiar-ation with therapeutic routines and personnel. For purpose of establishing productive relation be-een the therapists and the patient, this relation ould be established early in the recovery period that the usual early increments of achievement n be accomplished in this circumstance of coopera-n.

It should be recognized throughout the therapeutic fort that day-to-day variations in performance are be expected. Recognition of particular circum-ances of exacerbation of disability, such as acute fections or fatigue, will increase understanding of ese variations, but it must be admitted that there e other mechanisms and circumstances of variation hich are not separately identifiable.

Rehabilitation procedures should not impede res-ration and thus cause recapitulation of the respira-ry obstruction and hypoxia which these patients d commonly experienced during their acute illness. or example, if the patient has become dependent pon the easier route of respiration via tracheotomy, e tube should not be abruptly occluded but should covered with an inspiration-access valve or else artially occluded. Correspondingly, the initial efforts f swallowing should be upon a small bolus of liquid aterial with the subject semirecumbent in supine osition, to diminish risk of laryngeal penetration. he bolus in initial trial should be water or isotonic dium chloride solution, even though in many sub-cts it will later be found that a semisolid bolus of elatin, custard, or granular cereal is swallowed with ss difficulty than water.

In the patients having severe disability of swallow-g, the better therapeutic access to the patient is rough his speech. The speech therapist, who is par-icularly oriented to this therapeutic problem, is a aluable member of the rehabilitation group. The arly achievement of usable verbal communication s of much help in social rehabilitation of these pa-ients. In the varied performance of speech, there is vailable a succession of achievable therapeutic goals. pon the basis of comparative roentgenographic stud-es of motions in the tongue-hyoid-larynx column in honation and swallowing, it is, therefore, highly robable that the routines of speech therapy con-ribute to the elements of motor function which are equired for adequate swallowing function. There re also prospective therapeutic effects of speech ther-py upon the motor performance of the larynx, harynx, and mouth in recovery of valving action acilitating normal respiration.

In analogy to rehabilitation in other clinical circumstances of acute neurological impairment, it is advisable that the patient be returned to his family and community when he is psychologically ready for this transition as well as grossly capable of sustaining himself independently by his own motor efforts within it. Incident to this gradation, the therapeutic measures which are indicated and effectual in the individual patient should be continued if the therapeutic relation can be satisfactorily transferred to a family member or other familiar associate. At the time of this transition, it should also be anticipated that, in the more variable environment of the home and community, the circumstances of exposure to intercurrent illness and of psychological distress under extraordinary circumstances of fatigue will all be amplified and the lability of performance thus exaggerated.

PENICILLINASE IN THE TREATMENT OF PENICILLIN REACTIONS

Lieut. Commander Alexander M. Minno (MC), U. S. N. R.
and
Capt. George M. Davis (MC), U. S. N.

Penicillinase, an enzyme that destroys penicillin in vivo as well as in vitro, has been used in the treatment of 42 patients who had reacted unfavorably to penicillin. The most frequent reactions consisted of fever, urticaria, pruritus, and severe arthralgia in hands, ankles, and feet. The penicillinase was usually given intramuscularly in doses of 1 million units in 2 cc. of sterile distilled water. In some cases relief followed dramatically within a few hours; in others the symptoms continued to become more severe for 24 to 48 hours after the injection. Its effects were hard to evaluate because the severity of the penicillin reactions was variable and because some patients with moderately severe symptoms recovered completely within 24 hours after treatment with a placebo. Relief from the pruritus followed promptly after the injection in nearly every case. Two patients who had severe symptoms resembling serum-sickness and did not improve after treatment with steroids and antihistaminics obtained relief promptly after administration of penicillinase. Its only side-effects were local pain and tenderness at the site of injection.

Allergists inform us that today over 300,000 chemicals or substances are in use in treatment of patients by the medical profession. For practical purposes, however, only approximately 1,000 of these are in common usage. Any of these 1,000 substances potentially can cause hypersensitivity or toxic reactions. The variety of these reactions continues to increase until, at this time, the present-day physician must be informed not only of the multitudinous manifestations of the commonly known diseases but also of an ever-increasing chain of undesirable reactions due to drugs themselves. Although almost every issue of some medical publications warns us of an undesirable effect from one of the newer drugs, the most frequent and common reactions continue to be those in response to the two most commonly used drugs, aspirin and penicillin. The frequent urticarias and serum sickness–like reactions due to penicillin continue to harass us and tax our ingenuity in managing these annoying and often serious iatrogenic displays. Penicillin, yearly sales of which in these United States can now be expressed by the tons, is still the most commonly used antibiotic in all specialties of the medical profession. It is becoming rare and unusual to find a service recruit or serviceman who has not been given penicillin. Penicillin reactions have been variously estimated as occurring in from 0.1 to 5% of those receiving the drug. Consequently, penicillin reactions are a definite problem in the service and are a source of considerable morbidity.

Urticarial reactions and serum sickness–like reactions comprise the most commonly seen types of penicillin sensitivity response. Since the use of potent antimicrobial agents, the name "serum sickness" has lost its old significance and the process is now usually the result of drug reaction, with penicillin being by far the commonest offender.

Our therapeutic measures to alleviate these reactions have generally been limited to use of antihistamines, salicylates, calcium, epinephrine, and other sympathomimetic drugs, with the steroids being reserved for the more serious, prolonged, or severe manifestations of the disease. There is no known manner of predicting which of these reactions will clear promptly and which will progress on to tax our therapeutic armamentarium.

In 1956, in the *New England Journal of Medicine*, Becker[1] of Madison, Wis., reported that a single intramuscular injection of 100,000 to 800,000 units of penicillinase would reduce the circulating penicillin blood levels in human subjects receiving penicillin to zero within one hour; for periods of four to seven days later no penicillin could be detected in the blood, despite the fact that injections of penicillin were continued twice daily.

Penicillinase was discovered in 1940. It is produced by many strains of bacteria, including micrococci (staphylococci) and Escherichia coli. The enzyme used in this series of cases was derived from cultures of Bacillus cereus and produced by the Schenley Laboratories. The chemical manner of its action is thought to be that the penicillinase hydrolyzes penicillin to penicilloic acid, which is nonantigenic in penicillin sensitivity states. A unit of penicillinase is that amount of enzyme required to inactivate one unit of penicillin within one minute at 25 C at a pH of 7.0.[2]

From the U. S. Naval Hospital, Great Lakes, Ill.

Read before the Section on Military Medicine at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

Present Study

Since the suggestion by Becker that penicillinase might prove useful in the management of penicillin reactions, it has been used principally and often solely at the U. S. Naval Hospital, Great Lakes, Ill., for these reactions. Certainly, the theory behind its use is plausible and based upon the sound therapeutic dictum: "Where the allergen is known, the first and most plausible measure is to destroy or remove it." To date, penicillinase has been used in 32 cases. If there was any question as to whether penicillin was the causative allergen or if the patient's signs and symptoms seemed too minimal to draw any conclusions from the treatment, penicillinase was not used in his treatment.

Two principal types of reactions were observed, namely, urticaria with generalized pruritus and serum-sickness reaction. No anaphylactic reactions were seen. One case of hemorrhagic eruption confined to the legs and arms is included. The types of reactions treated were (*a*) fever, generalized urticaria with marked pruritus, severe arthralgia with redness, tenderness, swelling, and pain chiefly in the hands, ankles, and feet, 13 (of these 13, 3 had severe sore throat and one had a swollen, sensitive tongue); (*b*) generalized urticaria, general malaise, and joint manifestations without fever, 11; (*c*) urticaria and general pruritus without joint manifestations, 7; and (*d*) hemorrhagic eruption (arms and legs), one.

Of the 32 reactions treated, 14 were due to procaine penicillin and 18 were due to benzathine penicillin. No significant difference was observed in the severity of reaction characterizing either type.

Penicillinase was the sole agent of treatment in 12 cases. In the remaining 20 cases, the following drugs had been used prior to patients' treatment at the Great Lakes Naval Hospital: epinephrine, tripelennamine (Pyribenzamine), diphenhydramine (Benadryl), ephedrine, steroids, and/or chlorpheniramine (Chlor-Trimeton). The antihistamines were usually continued, but all other medicaments except penicillinase and the antihistamines were discontinued. The 20 patients had had previous treatment as follows: antihistamines, aspirin, and steroids, 2; salicylates, epinephrine, and antihistamines 4; and antihistamines alone, 14.

The results of treatment with penicillinase were impressive and encouraging. The reactions to benzathine penicillin responded on the average as quickly as those to procaine penicillin. These results can be summarized as follows: ambulatory and asymptomatic within 24 hours, 15 patients; ambulatory and asymptomatic within 48 hours, 5; and symptoms and signs abating, but four to six days before all signs and symptoms disappeared, 12.

It is our impression that this treatment has rendered the patient more rapidly asymptomatic and free from relapse than other commonly used modes of treatment. When compared with the results obtained in treating 14 hospitalized patients prior to the use of penicillinase, these results were striking. The usual dose administered was 1 million units in 2 cc. of sterile distilled water, intramuscularly. In eight cases, the single dose was sufficient to effect apparent cure. One patient received the injection intravenously by mistake. It is of interest that, in his case, urticaria disappeared within six hours and he had no further complaints. A second patient received 500,000 units of penicillinase intravenously, and, within 45 minutes, she developed a severe shaking chill with high temperature, nausea, and slight cyanosis. She responded promptly to therapy with epinephrine and corticotropin given intravenously. A single intramuscular injection of 2 million units was used in six cases, and relief was obtained within 24 hours in four of these cases. In those instances of severe reactions wherein response was not definitely beneficial within 48 hours, injections were repeated in 48 hours. In 11 cases, more than two injections were given, and in 5 of these we were experimenting with smaller doses given at more frequent intervals. In one patient with severe serum sickness response was apparent after a single injection of 1 million units of penicillinase, in that complete clearing was noted in four days. One week later, he again developed severe joint manifestations with urticaria. After three days' treatment with antihistamines and epinephrine, he was hospitalized and given penicillinase again, with complete clearing after four days.

No toxic manifestations were encountered in the intramuscular use of penicillinase, although most patients complained of local pain and residual tenderness at the site of injection. The area frequently remained painful for 24 hours.

Penicillin blood level prior to penicillinase therapy was demonstrable in only three cases. After penicillinase therapy no penicillin level could be found in these cases. In one case a significant penicillinase blood level was still present 14 days after his treatment with one injection of 1 million units of penicillinase. It is the current belief of the Navy Medical Research Unit 4, who performed these determinations, that penicillin levels in the urine can be demonstrated more readily than in the blood. We are currently investigating this.

Since use of penicillinase, no necessity to use steroids has arisen, in spite of the fact that many of the patients treated had severe manifestations of serum sickness. Three of these had severe sore throats and one, swelling of lips and tongue. Two of the group, who had been started on therapy with steroids plus antihistamines without significant benefit, were taken off steroid therapy and given penicillinase, with prompt improvement and relief in each case, without recurrence.

Comment

Accurate determination of the effect of any agent *in the treatment* of penicillin reactions is difficult. The severity of the reactions is so variable that sound conclusions as to the influence of any treatment must await critical analysis and prolonged usage. We were particularly impressed by this difficulty in determining the effects of therapy, as opposed to the fluctuations of the disease, when four of our moderately severe serum-sickness reactions cleared within 24 hours after placebo treatment alone and four others within 48 hours. A number of patients with minimal to moderate urticaria were simply observed, and the reaction cleared promptly without treatment. Heat and exercise definitely tend to aggravate a reaction; hence, the simple expedient of reducing activity is often rewarded with relief. Dermographia was prominent and present in each reaction observed. The presence of erythema, tenderness, angioneurotic edema, and urticaria, particularly over the pressure points in the palms and under leggings and shoes, was striking.

It is our impression that penicillinase is therapeutically effective. Penicillinase is not a panacea for all penicillin reactions. On occasions, it appeared to effect relief dramatically within a few hours. On other occasions, the chain of hypersensitivity reactions grew more severe for periods of 24 to 48 hours after use of penicillinase alone or combined with antihistamines. We have been impressed, however, that its use, when combined with antihistamines, lessens morbidity and decreases patient discomfort; the likelihood of recurrence is reduced and the need for steroids is virtually eliminated. It is definitely safe when used intramuscularly. We are further impressed by the prompt relief of itching which was noted in nearly every case in which penicillinase was used. Although treatment was not elected in those patients seen early, when the manifestations of reaction were minimal, probably the use of penicillinase as soon as the diagnosis is apparent would result in the best and most prompt response.

It is our opinion that antihistamines and penicillinase are complementary and that combined use reduces the morbidity of this relatively common iatrogenic disease. The advantages of such safe treatment in recalcitrant cases wherein steroid therapy may be hazardous or contraindicated, as in diabetics, patients with hypertension, and cardiacs, are self-evident. As one might expect, once a definitely severe inflammatory reaction has developed associated with severe joint manifestations, even though the circulating allergen has been effectively removed or detoxified, some further time must elapse to allow complete regression. This may account for the longer time intervals in complete healing in certain cases and indicates a need for institution of therapy as promptly as possible.

Summary

The use of penicillinase in the treatment of hypersensitivity reactions to penicillin is based on the logical knowledge that circulating penicillinase reduces all demonstrable penicillin blood levels to zero for prolonged periods of time, thus rendering the penicillin nonallergenic. When used in 32 cases of moderate to severe hypersensitivity reactions to penicillin, the results of treatment with penicillinase were definitely encouraging and apparently superior to measures previously in standard use.

Addendum

Since the preparation of this report, 10 additional patients with penicillin reaction have been treated, each with a single intramuscular injection of 1 million units of penicillinase. One of these patients required hospitalization and a total of five days of observation after treatment. The remaining nine did not require hospitalization; eight were well in 48 hours and one in 72 hours.

Asthma in Young Boys.—Many people who are called upon to deal with asthma patients in this intermediate stage of their lives [6-16 years] are inclined to overtreat them. . . . This is not necessary. It is to be remembered, that reassurance of the young patient is vital. It is important that the doctor should try and make himself available to the young patient whenever required, for if he knows that the doctor will always come to his aid, it will greatly increase his confidence and that of his parents. An anxious parent may, by his or her behaviour, be the trigger mechanism which sets off the attack. The third point is, that it is important that not too much emphysema should develop before breathing exercises and postural exercises are instituted. Under these methods the children appear, literally, to grow out of their ailment of their own accord. If on the other hand the child be left to "grow out of it" by himself, and only symptomatic treatment is given, then a most unhappy state of affairs may eventuate for both patient and parent, causing them endless anxiety and suffering.—M. Helman, M.B., Ch.B., Asthma in Young Boys, *South African Medical Journal*, Oct. 13, 1956.

PROLONGED TREATMENT OF RHEUMATOID ARTHRITIS WITH PREDNISONE (METICORTEN)

Abraham Cohen, M.D., Richard F. Turner, M.D., William L. Kanenson, M.D., Philadelphia
and
Joel Goldman, M.D., Johnstown, Pa.

Evaluation of treatment of rheumatoid arthritis with prednisone for more than a year leaves little doubt that prednisone and the related steroid, prednisolone, are steroids superior to cortisone, hydrocortisone, and corticotropin. Three important advantages of prednisone have become established, namely, a lack of sodium retention, the absence of increased potassium excretion, and the unlikelihood of the production of hypertension during its use. The incidence of duodenal ulcer was found to be no greater than that encountered in the normal population. Thorn tests were done in a large group to determine possible depression of the adrenal gland. Remission or improvement can sometimes be obtained with prednisone in patients whose treatment with cortisone or hydrocortisone has been unsatisfactory because of undesirable effects or diminution in effect.

The treatment with prednisone for periods of a year more of a group of patients with rheumatoid ar- ritis afforded an opportunity to evaluate the effects prolonged administration of this corticosteroid. series of 33 patients with severe rheumatoid arthritis eated with prednisone was originally reported.[1] nce then, the series has increased to 132 patients. he longest period of treatment at the time of the iginal report was 20 weeks. The information gained om prolonged treatment is presented in this report, id original impressions of the outstanding antirheu- atic and anti-inflammatory properties of prednisone e confirmed.

Material

The 132 patients with rheumatoid arthritis included whose disease was acute. Among those with chronic ases, the disease had existed for 6 to 12 months in 3 patients and for longer than one year in 92. Symp- oms had been present for periods ranging from a few ays to 30 years.

Practically all ages were represented. The youngest atient was 17 years old and the oldest 75 years of ge. The sex ratio was 4:3, as there were 76 female nd 56 male patients.

The following concomitant conditions were present the numbers of patients indicated: diabetes mellitus, ve; active duodenal ulcer, one; inactive duodenal lcer, two; moderately severe hypertension, two; and r-advanced symptomatic ulcerative colitis, one.

Forty patients received prednisone as initial anti- eumatic therapy. Ninety-two patients had previously een treated with steroids, gold, and phenylbutazone, s follows: corticotropin, 8; cortisone or hydrocorti- one, 54; gold, 20; and phenylbutazone, 10. Sometimes ese agents were used in combination. The 54 pa- ients' treatment was unsatisfactory with cortisone or ydrocortisone because of side-effects, toxicity, or iminution in the effect of the steroid. The 20 patients ormerly treated with gold represent a selected group n that all had had toxicity reactions to gold.

The appearance of edema with subsequent congestive heart failure in two patients had caused the withdrawal of cortisone. Hypertension had developed during the administration of cortisone and corticotropin (ACTH) in two patients each. It is possible that some degree of hypertension may have existed prior to steroid therapy. All four of these patients showed relatively marked hypertensive retinopathy.

The criteria of the American Rheumatism Association were used to establish the stage of the disease at the time prednisone administration was begun. No destructive changes were present in 20 patients classified in stage 1. The disease in more than half of the patients, 64, was in stage 2, in 40 patients in stage 3, and in 8 patients in stage 4.

Functional capacity was likewise determined by the criteria of the American Rheumatism Association. The following table coordinates the stage of the disease with patients' functional capacity at the beginning of treatment.

Functional capacity was unimpaired in 14 patients in stages 1 and 2. Eighty-one patients in the first three stages were able to carry on normal activities despite discomfort and limited motion. The remainder of the patients were limited as to activity and unable to work, but were able to care for themselves. No patient was bedridden.

Methods

When prednisone was first used, 60 mg. daily was sometimes administered. A large initial dosage subsequently proved unnecessary in rheumatoid arthritis.

From the Arthritis Clinic, Philadelphia General Hospital (Drs. Cohen, Turner, Kanenson, and Goldman) and the Department of Medicine, Jefferson Medical College (Dr. Cohen).

The plan for dosage that evolved with experience follows: Treatment was commenced with 5 mg. of prednisone every six hours, day and night, for one week. With this regimen, symptomatic relief usually occurred within 12 hours. On rare occasions, it took 24 or even 48 hours for symptoms to be relieved. At the end of the first week of treatment, when the patient had improved, the dosage was reduced to 17.5 mg. daily. Reduction in dosage by decrements of 2.5 mg. weekly was continued as long as no symptoms returned. In this way, a maintenance dosage of 2.5 to 15 mg. daily usually was not exceeded. If symptoms returned as the dosage was diminished, the next higher dose was repeated and a new attempt at reduction followed. The duration of treatment, in general, varied from three months to one year, but some patients were under treatment for 18 months.

TABLE 1.—*Functional Capacity Before Therapy*

	Class				
	1	2	3	4	Total
Stage					
1	6	13	1	0	20
2	8	36	20	0	64
3	0	32	8	0	40
4	0	0	8	0	8
Total	14	81	37	0	132

Results

No patient failed to show some response to prednisone. The response, judged by the American Rheumatism Association classification, was grade 1 improvement, that is, complete remission, in 39 patients (table 2). No signs of joint inflammation remained but irreversible deformities, of course, were unaltered. Among patients in remission, the disease at the start had been in stage 1 in 4 patients, stage 2 in 15 patients, and stage 3 in 20 patients.

Major improvement with minimal residual joint signs (grade 2 improvement) took place in 89 patients. The disease in 8 patients initially was in stage 4, in stage 3 in 19 patients, in stage 2 in 47 patients, and in stage 1 in 15 patients.

The remaining four patients improved to a minor degree (grade 3 improvement), some swelling still being present. However, no extension of rheumatoid activity was occurring to new sites. The disease in these four patients, except one, was in its early stages.

With few exceptions, the degree of improvement noted at the time of evaluation could be maintained. In an insignificant number of patients, prednisone seemed to become less effective as treatment was continued. It had to be kept in mind that the adrenal gland can be depressed by continued high dosage of corticosteroids. This makes it mandatory for the physician to arrive at the dosage that will produce a remission but not an untoward reaction.

While the relief of symptoms occurred in most patients within 12 hours, in some it occurred within 4 to 8 hours. Pain and tenderness around affected joints began to diminish. Stiffness, especially that noted e in the morning, diminished after one or two d In two days also, inflammation about the joints be to disappear. As the range of motion of affected jo increased, the patients were able to do such sir things as reach their heads with their hands and f themselves, which previously had been impossible some of them.

Joint measurements were made and swelling, m cle power, and redness about the joints were stud at each visit. C-reactive protein tests were not p formed, since this test is considered unrelia Eosinophil counts were made on 24 patients. The d in circulating eosinophils four hours after a single c dose of 20 mg. of prednisone ranged from 54 to 10 Erythrocyte sedimentation rates, initially elevated, d creased during therapy in all patients except one.

After proper therapy for congestive heart failu the two patients in whom this complication occurr as a result of cortisone administration fared well wh treated with prednisone. Retention of sodium, ma fested by edema, did not occur with prednisc whereas symptoms of cardiac decompensation we aggravated by cortisone.

Blood Pressure.—The blood pressure level of cli patients was determined at each visit, and record daily for ward patients. As previously reported, mo erately severe hypertension present in two patie prior to treatment showed no alteration. However, blood pressure rose to a hypertensive level dur the administration of prednisone in two other patie Perhaps some degree of hypertension existed prio therapy, but this is not known. Eight patients, pr ously normotensive, had a gradual rise in blood p sure during the first week of therapy. Thereafter, t blood pressure slowly reverted to normal levels. of these patients had grade 2 hypertensive retin angiopathy, indicating earlier burned out hyperte sion. The four patients previously hypertensive duri cortisone or corticotropin treatment became norm tensive when prednisone was substituted.

TABLE 2.—*Grade of Improvement*

	Grade				
	1	2	3	4	Total
Stage					
1	4	15	1	0	20
2	15	47	2	0	64
3	20	19	1	0	40
4	0	8	0	0	8
Total	39	89	4	0	132

Hematopoietic System.—Hemoglobin determinatio and red blood cell counts were performed on all p tients. When anemia was present, hemoglobin leve and red blood cell counts usually rose within a short time after improvement occurred in the joints.

Gastrointestinal Tract.—Three patients with peptic ulcer were treated with prednisone without misha despite activity of the ulcer in one instance. Duodena ulcer was first demonstrated by roentgenographi mination in one patient in 1949. Little change oc- red in the lesion during the following year. Predni- e administered from Aug. 23, 1955, continuously more than a year caused no progression of the er, the last roentgenographic examination having en made on Aug. 27, 1956. The patient remains on rapy with a maintenance dose of 15 mg. of predni- e daily with Aludrox (aluminum hydroxide gel th magnesium hydroxide) between meals. He is nptom-free. Two patients with inactive asympto- tic duodenal ulcer received prednisone. In a male tient with no complaints referable to the gastroin- tinal tract, a chronically scarred duodenal cap had en discovered by gastrointestinal series in 1951. No ange occurred in the scarring, but a gastrointestinal ies after five months' treatment with prednisone owed pylorospasm. This patient is maintained on erapy with 15 mg. of prednisone daily with Aludrox tween meals. He complains occasionally of epigastric stress.

In May, 1951, roentgenographic examination in a oman showed marked deformity of the duodenal lb. Examined again in January and November, 1955, e cloverleaf deformity was concluded to represent arring from chronic ulceration rather than a definite ater. Prednisone was first given on Nov. 23, 1955. is patient's condition can now be maintained with mg. of prednisone daily with Aludrox between eals. She complains only occasionally of epigastric stress. The radiographic examination on Aug. 1, 56, showed no evidence of activity of the ulcer.

A duodenal ulcer in a female patient ruptured sud- nly during therapy. No gastric distress or symptoms ferable to the gastrointestinal tract preceded this isode, so it was a most unexpected occurrence. The pture was closed surgically. Reactivation of the thritis developed. Prednisone was again adminis- red. The maintenance dose is 10 mg., and the patient symptom-free. There has been no recurrence of e ulcer.

A patient with an inactive asymptomatic duodenal cer received prednisone. This fact that an ulcer was esent was unknown to us at the time. The patient mplained of ulcer symptoms on the 25th day of eatment, at which time a gastrointestinal series dis- osed a large ulcer niche.

Mild epigastric distress occurred in another patient uring treatment, but no ulcer could be demonstrated. ar advanced ulcerative colitis in one patient could be ontrolled for six months with a maintenance dosage f 15 mg. of prednisone daily. The patient, however, as lost to subsequent follow-up.

Carbohydrate Metabolism.—Five patients with dia- etes mellitus received prednisone. Three required dditional insulin by as much as 50% for control. The ourth patient required no additional insulin.

The fifth diabetic patient, with severe rheumatoid rthritis, was brought into the hospital in diabetic oma. With little alernative except to chance therapy ith steroids, cortisone was administered. The patient fared well under steroid therapy, which eventually was changed to prednisone. She still is under our care and doing well. The blood sugar level has not been disturbed since standardization was achieved.

Electrolyte Studies.—At the beginning of the study of prednisone, serum sodium and potassium determinations were made routinely. When it was established that they were unnecessary, the studies were discontinued. Serum sodium levels showed no tendency to increase and serum potassium levels showed no decrease below pretreatment levels in patients receiving prednisone for prolonged periods. No patient complained of muscular weakness or lassitude and no supplemental potassium was needed.

Side-actions.—The most prominent side-action accompanying prolonged administration of prednisone was moon facies in 70 of the 132 patients. Acne in one patient, and acne and hirsutism in another, which developed when the patients received cortisone, persisted when prednisone was substituted. No other untoward effects occurred, except those already mentioned in reference to carbohydrate metabolism, blood pressure elevation, and the gastrointestinal tract.

Thorn Tests.—Eosinophil counts were made on the blood of 78 patients after fasting in preparation for the Thorn test. The maintenance dosage in these persons had been 15 mg. of prednisone daily for from 2 to 12 months. Each then received 40 units of corticotropin intramuscularly and was required to return in four hours. The patient partook of neither food nor drink during this period of time. Upon his return to the laboratory, a second eosinophil count was made. If the reduction in eosinophils was less than 50%, the test was considered negative and interpreted to mean that the adrenal cortex was inactive, as the result of prednisone therapy. In this test, 60, or 77% of the 78 patients, showed a positive reaction, indicating no disturbance of adrenocortical function, and 18, or 23%, a negative result, which is interpreted to indicate that there is some depression of the adrenal cortex. In the majority of patients, therefore, no depression of the adrenal gland resulted from the administration of prednisone.

Comment

Evaluation of treatment of rheumatoid arthritis with prednisone for more than a year leaves little doubt that prednisone and the related steroid, prednisolone, are steroids superior to cortisone, hydrocortisone, and corticotropin. Prednisone possesses outstanding antirheumatic and anti-inflammatory properties. Three important advantages of prednisone have become established, namely, a lack of sodium retention, the absence of increased potassium excretion, and the unlikelihood of the production of hypertension during its use. Remission or improvement can sometimes be obtained with prednisone in patients whose treatment with cortisone or hydrocortisone has been unsatisfactory because of undesirable effects or diminution in effect.

Among rheumatoid arthritis patients who can tolerate gold, a large percentage will probably do well under treatment with this substance. This could prove advantageous because therapy with steroids brings about only temporary cessation in the activity of the disease. Conceivably, the combination of gold with one of the newer steroids might achieve more permanent benefit in rheumatoid arthritis.

A possible disadvantage of prednisone is the fact that the majority of patients receiving it sooner or later develop rounding of the face. However, facial rounding was not troublesome in the 70 patients reported here. Despite the reactivation of a duodenal ulcer and the rupture of a symptomless duodenal ulcer, the incidence of peptic ulcer seems to be no greater with prednisone than with the older corticosteroids. The lack of progression of lesions in three patients with active duodenal ulcer or chronically scarred duodenal caps supports this view.

After experience with larger dosages, it seems best to commence treatment with prednisone with a relatively low dosage, 20 mg. daily. The dosage can gradually be reduced as the patient improves. The dose should be increased if the patient complains of stiffness in the joints in the early morning hours before arising, or if soreness or tenderness is present. Our maintenance dosages ranged from 2.5 to 15 mg. daily. Only rarely did the amount have to be increased to 30 mg. daily. When this became necessary, a dosage reduction schedule was repeated.

Summary

One hundred thirty-two patients with rheumatoid arthritis in various stages were treated for three months to a year or more with prednisone, one of the newer adrenocortical steroids. The effects of prolonged administration of this substance were evaluated. Forty patients received prednisone as initial antir matic therapy. In 54 patients, previous treatment w cortisone or hydrocortisone had proved unsatisfac because of toxicity or escape from control. Tw patients were transferred to therapy with predni because of toxicity reactions to gold. Each of the tients showed a favorable response. Complete r mission occurred in 39 patients, in approximately of whom the disease was in stage 3 at the beginnin prednisone therapy. Major improvement occurred 89 patients. In more than half of this group, the dise had been in an advanced stage. Prednisone posses certain advantages over cortisone, hydrocortisone, a corticotropin (ACTH), namely, absence of sodium r tention and of increased potassium excretion, and t unlikelihood of production of hypertension during administration.

Rounding of the face occurred in 70 patients being the most prominent side-action. One pati with an active duodenal ulcer and two with chronic ly scarred duodenal caps were treated without pr gression of their lesions. Activation of a duodenal ulc occurred in one patient, and in another with no sym toms referable to the gastrointestinal tract, a ruptur duodenal ulcer required surgery. Despite th occurrences, and in view of the treatment of th patients with ulcer without mishap, the incidence peptic ulcer during prednisone and prednisol therapy seems not to exceed that encountered w the older adrenocortical steroids.

Prednisone as Meticorten was furnished by George Bab Jr., M.D., Division of Clinical Research, Schering Corporat Bloomfield, N. J.

Eclampsia in New Zealand.—A Dominion-wide investigation of eclampsia over a period of nearly 30 years, made possible by general notification of eclampsia in New Zealand . . . indicates very striking reductions in incidence, from 3.2 per 1,000 births to 1.02 per 1,000; in maternal mortality rate, from 18.9 per cent to 1.7 per cent; in maternal deaths, from 0.6 per 1,000 total births to 0.03 per 1,000; and in infant mortality rate, from 42 per cent to 13.6 per cent. . . . Reduction in severity is further shown by the fact that in the last 6 years, 1950-1955, 63 per cent of the cases were extremely mild type with survival of both mother and infant and no more than 3 fits, whereas in the first period, 1928-1933, only 16 per cent of the cases were in this category. A very important change in the pattern of eclampsia is the ever-increasing proportion of cases now occurring in the late second stage or early post-partum period where, in the main, they are of very mild type and quickly amenable to control by relatively simple measures. Another remarkable change in the pattern of toxaemia as a whole is the very much greater proportional reduction of eclampsia deaths by comparison with other toxaemia deaths which are of a more purely hypertensive type. In more recent years, even in those cases of eclampsia which did prove fatal, the eclamptic element was completely overshadowed by acute cardiovascular incidents. These facts are surely a complete vindication of the value of antenatal care even in our present state of incomplete knowledge of causation. For without question these results were essentially due to preventive measures carried out with care and conviction by the majority of the doctors throughout the country.—T. F. Corkill, M.D., Eclampsia—Changes in Pattern, *The Journal of Obstetrics and Gynaecology of the British Empire*, February, 1957.

DRY FENESTRA NOVOVALIS OPERATION

TECHNIQUE FOR RESTORATION AND CONSERVATION OF SERVICEABLE HEARING IN CLINICAL OTOSCLEROSIS

Julius Lempert, M.D., New York

The labyrinthitis that has often followed fenestration operations was explained in part by the appearance of blood in the perilymph space but also in part by the use of irrigating solutions which did not duplicate the unknown composition of the perilymph. The irrigation necessary for the removal of bone dust is now done before opening the perilymph space, and the subsequent creation of bone dust can be avoided by removing the bony cupola intact instead of using the pulverization technique. One hundred fenestration operations have been performed alternately with and without irrigation, so that in 50 patients the ear was irrigated and in 50 it was not. Bleeding into or within the perilymph space was prevented in every one. There was labyrinthitis of some degree of severity in each of the 50 irrigated cases, and it was absent in all of the 50 nonirrigated cases. The new vestibular fenestra must be made in a region out of reach of the spreading otosclerotic lesion, for permanency of effect; for acoustical reasons, the fenestra is placed outside of the middle ear. The middle ear space is acoustically sealed off. The new vestibular fenestra being likewise covered and sealed off, and being without any direct connection with the middle ear, a maximum difference in sound pressure between them is attained. This gives the most marked and most lasting possible improvement in hearing.

Otologists everywhere, interested in the improvement and perfection of the fenestration operation, were trying to determine the cause of the inflammatory reaction of the endolymphatic labyrinth, always a postoperative occurrence, varying only in the degree of its severity, as judged by the postfenestration clinical picture. George Shambaugh Jr. suggested, logically, that blood entering the perilymph space during the fenestration operation can cause postoperative serous labyrinthitis of a greater or lesser degree, varying according to the amount of blood entering the perilymph space. He proved, experimentally, in the monkey, that, by permitting quantitatively different amounts of blood to enter the open perilymph space of the fenestra in the external semicircular canal, several varied degrees of postoperative labyrinthitis could be produced. Nevertheless, the question still to be answered was "Will the avoidance of the technical error of permitting blood to enter into or start within the perilymph space prevent the onset of postoperative serous labyrinthitis?"

Careful observation of the sources of origin of free blood in the perilymph space led me to devise techniques for preventing both the bleeding into and the bleeding within this area. In spite of this, however, I was unable to prevent in any of my patients the onset, postoperatively, of the clinical picture suggestive of serous labyrinthitis in various degrees of severity. It thus became obvious to me that, (1) although it is true that bleeding into or within the perilymph space does cause postoperative labyrinthitis, (2) it is also a fact that even the most meticulous avoidance of blood entering into or starting within the perilymph space does not per se prevent postoperative onset of inflammatory reaction involving both the vestibular and the cochlear endolymphatic labyrinth, in varying degrees of severity. These observations caused me to believe that blood within the perilymph space is not the only cause of postoperative labyrinthitis.

Irrigation and Suction as Cause of Labyrinthitis After Fenestration

If, however, the constancy of the postoperative occurrence of serous labyrinthitis is to be explained, there must exist still another, hitherto-unrecognized, technical error, constantly being made in the performance of the fenestration operation, which always causes various degrees of inflammatory reaction of the membranous labyrinth. It occurred to me that irrigation and suction with any one of the physiological solutions used to date, for whatever purpose, after the vestibular perilymph space has been laid open, may be the one technical error always causing postoperative inflammation of the membranous endolymphatic labyrinth despite the meticulous avoidance of all the other technical errors which could cause it. The postoperative inflammatory reaction may be either a chemical phenomenon produced by irrigation or a mechanical one produced by the suction accompanying the irrigation.

From the Lempert Institute of Otology, Lempert Research Foundation, Inc.

Honorary Chairman's address, read before the Section on Laryngology, Otology, and Rhinology at the 106th Annual Meeting of the American Medical Association, New York, June 4, 1957.

Irrigation in the region of the open perilymph space inevitably results in the replacement of the perilymph within the perilymph space with the fluid used for irrigation. The chemical difference of the fluid replacing the human perilymph may cause inflammatory reaction of the membranous endolymphatic labyrinth. Since the chemistry of the human normal perilymph is still unknown, there is no way of telling whether or not any physiological solution presently employed for irrigating the newly created fenestra region can effectively take the place of the natural perilymph which irrigation and suction removes from the perilymph space. It is not known if any of these solutions can be tolerated within the perilymph space for any length of time without causing inflammatory reaction of the delicate membranous endolymphatic labyrinth. None of the physiological solutions heretofore suggested for replacing isotonic sodium chloride solution or Ringer's solution for irrigating the perilymph space seemed to prevent the postoperative onset of inflammatory reaction of the endolymphatic labyrinth in varying degrees of severity, as judged by the duration and severity of the postoperative vertigo and recruitment.

The mechanical effect of the suction force upon the delicate membranous walls of the endolymphatic labyrinth cannot be dismissed without being suspected also as a possible cause of the postoperative inflammatory reaction of the membranous endolymphatic labyrinth.

Based upon the supposition that the effect of the chemical difference between the fluid used for irrigation and that of the human perilymph which has been replaced by it (within the perilymph space), as well as the mechanical effect of the suction force upon the membranous endolymphatic labyrinth, may be responsible for the postoperative inflammatory reaction of the endolymphatic labyrinth, I decided to conduct definitive tests. These tests would determine whether the constantly used irrigation and suction, with subsequent replacement of the perilymph with any of the currently used solutions which are different from perilymph chemically, can assuredly be held responsible for the constancy of postoperative serous labyrinthitis following fenestration surgery. In addition to avoiding the heretofore-proved causes of serous labyrinthitis, I would also have to avoid irrigation and suction altogether after opening the perilymph space, in a series of cases, in order to observe whether or not the postoperative labyrinthitis can thereby be consistently and consecutively prevented.

The tests were carried out on a series of 100 patients. I consecutively fenestrated 100 ears deafened as a result of otosclerosis, in the presence of good hearing by bone conduction, alternating between irrigation and nonirrigation, so that in 50 patients the ear was irrigated, and in 50 it was not. The previously proved causes of postoperative inflammation were carefully prevented. Bleeding into or within the perilymph space was prevented in every one of the 100 patients.

The results appear conclusive. I observed that, in the 50 patients in whom irrigation and suction were not used after the perilymph space had been opened, there was no clinical evidence of postoperative inflammatory reaction of either the vestibular or the cochlear endolymphatic labyrinth. Of the 50 patients in whom irrigation was used, however, all showed postoperative signs of labyrinthitis in various degrees of severity. I have thus proved to my satisfaction that irrigation and suction, after the vestibular perilymph space has been opened, is the constant cause of postoperative inflammatory reaction of endolymphatic labyrinth.

It thus became obvious that the fluid most physiologically suitable for surrounding the membranous labyrinth must be natural perilymph. It is apparent also that the best way to prevent postoperative inflammation of the endolymphatic labyrinth is to permit the labyrinth to continue bathing in Nature's perilymph instead of in any other solution which cannot possibly be made "physiological" to the membranous endolymphatic labyrinth so long as the chemical composition of the human perilymph remains unknown.

However, irrigation and suction after the vestibular perilymph space has been opened can be avoided only by technically performing the fenestration operation without creating the need for irrigation, once the perilymph space of the vestibular labyrinth has been laid open. *The necessity for the use of irrigation after the vestibular perilymph space has been opened can be avoided only by (1) using irrigation prior to opening the perilymph space for the removal of all bone dust and (2) employing* the cupola technique and removing the bony cupola intact instead of using the pulverization technique for opening the perilymph space, thus avoiding the creation of bone dust and removing the necessity for irrigation after the perilymph space has been opened.

Postoperative inflammatory reaction of the vestibular and cochlear membranous endolymphatic labyrinth after the fenestra novovalis operation can now be consistently avoided with the use of the dry fenestra novovalis technique. Since the technique for prevention of postoperative osteogenetic closure of the fenestra novovalis had been previously perfected and time-proved, the technique for prevention of postoperative serous labyrinthitis which has finally been developed results in removal of the final stumbling block to completely successful fenestration surgery.

Requirements of Fenestra Novovalis Technique

Obviously, surgery aimed at improvement of hearing in clinical otosclerosis is now an established and recognized achievement. But to be consecutively, consistently, and abundantly successful in the restoration of serviceable hearing and in the permanent maintenance thereof in an ear deafened by ankylosis of the stapediovestibular joint of otosclerotic origin, the technique employed must meet the following requirements:

1. The over-all procedure must include means for predicting preoperatively the possibility of surgically improving the hearing for airborne sound (by surgically remobilizing the inner ear fluids) to at least the 30-db. level or higher, in the 512, 1,024, and 2,048 frequencies, the speech frequencies. The ability to hear at these levels, which should be evident immediately, on the operating table, is necessary for practical, serviceable, unaided hearing acuity.
2. The surgical technique employed should be capable of improving the hearing in a given ear, no matter how low the preoperative audiometric reading for airborne sound happens to be for the three frequencies, so long as the masked bone-conduction hearing for pure tone in these frequencies has not fallen below the 20-db. level.
3. The technique employed must incorporate definitely prescribed, time-proved means for deliberately conserving and permanently maintaining the hearing newly regained by the operation.
4. To reach the above-mentioned three objectives, it is essential that the basic principle of the technique employed should consist of the surgical creation of a new covered vestibular window outside of the middle ear to replace the functionally impeded covered oval window within the middle ear.
5. It is of functional importance that the new fenestra be placed outside of the middle ear. To prevent the newly created vestibular fenestra from eventually becoming functionally impeded by the progressively spreading otosclerotic tumor, it is essential to create a new vestibular fenestra outside the otosclerotic oval window fossa in a region out of reach, as a rule, by the otosclerotic lesion.
6. Functional permanency is of importance in the new fenestra. A newly created vestibular fenestra cannot be left uncovered without jeopardizing not only the patient's cochlear nerve function but his very life as well. The fenestra must be isolated from the tympanic airspace without leaving any direct connection between the middle ear and the new window to prevent postoperative labyrinthine infection secondary to onset of middle ear infection during the life span of the patient. A time-proved means for the prevention of ultimate osteogenetic closure of the newly created vestibular fenestra must also be provided to insure the functional permanency of such fenestra.
7. It is of acoustical importance that the new vestibular fenestra be placed outside of the middle ear and be covered and sealed off without leaving any direct connection between the middle ear and the new vestibular window. To increase the sound pressure difference between the round cochlear window and the surgically created vestibular window, it is essential to have the middle ear space acoustically sealed off. This way the sound pressure acting upon the intratympanic cochlear window is relatively smaller than the sound pressure acting on the newly created extratympanic vestibular window.

It should be emphasized that the secret of both the immediate restoration and permanent conservation of serviceable hearing in middle ear deafness of otosclerotic origin, with surgical means, lies in replacing the functionally impeded intratympanic vestibular fenestra ovalis with a newly created extratympanic vestibular fenestra within the wider bony ampullar portion of the external semicircular canal immediately posterolateral to the tympanic course of the facial nerve canal.

The fenestra novovalis operation was developed by observation, consideration, and ultimate application of the above-mentioned requirements. This is the reason why this type of operation makes it possible not only to predict preoperatively but also to obtain postoperatively the maximum obtainable and permanently maintainable hearing improvement in clinical otosclerosis.

Antibiotics in Food Preservation.—Antibiotics have been suggested for use in . . . foods, such as milk, eggs, and fresh vegetables. Because antibiotics may inhibit starter cultures used in cheese manufacture, dairy products that are going to be used for the production of cheese should under no circumstances contain antibiotics. Although there are glowing reports of the advantages to be realized from use of antibiotics, it is well to sound again a note of caution. Regulatory officials in the United States believe their safety has not been established for most of the proposed uses. The status of antibiotics in food in the United States is: They may be used so that no residues remain in the food. This is acceptable. They may be used so that residues remain in the uncooked food. This is acceptable provided the food is always cooked and the cooking always destroys all of the antibiotic (and in the United States provided the residues in the uncooked product are within an official tolerance). They are being considered for uses which will leave some of the antibiotic in the food as it is eaten. Their safety under these conditions has not been established.—C. G. Durbin, Antibiotics in Food Preservation, *American Journal of Public Health and the Nation's Health,* October, 1956.

ADVANCES IN OTOLOGY

Gordon D. Hoople, M.D., Syracuse, N. Y.

In considering otological advances to overcome hearing loss, it is almost right to say that no case of conductive hearing loss is without possible help by surgery. In the case of perceptive hearing loss, however, future advances will probably be more preventive than therapeutic. Among many causes of perceptive hearing loss, at least four are on the verge of a preventive solution. These are hearing loss due to (1) the difficulties of Rh-negative pregnancy; (2) the loss of proper blood supply to the ear following atherosclerosis; (3) allergic sensitivity which may cause degeneration of the nerve of hearing; and (4) loss of hearing due to exposure to industrial noise. Probably the major reason today for improvement in the avoidance of hearing losses is the curtailment of infections.

I should like to review hearing losses as otolaryngology has looked upon them during my professional lifetime. I entered otolaryngology about the time that the audiometer was first available for clinical use. I had my training in one of the best institutions in the United States and received it from the hands of most competent men, including the finest pedagogue otolaryngology has ever known, the late Dr. Harris P. Mosher. There was no audiometer in clinical use during all of my residency, and I practiced for a few years without the aid of such an instrument.

Early Diagnostic and Remedial Methods

It is interesting, in the light of modern otology, to realize what one could accomplish with whispered and spoken voice tests together with tuning forks and the Galton whistle. Patients with pure perceptive and pure conductive hearing losses could be isolated, but patients with mixed losses were less satisfactorily classified. There was no general recognition then that a person with otosclerosis might have some concomitant nerve degeneration. As a matter of fact, many cases of otosclerosis went undiagnosed, for the teaching of that day laid stress upon the statement that a patient with otosclerosis must have a patent eustachian tube and a normal drum head. This was tantamount to suggesting that infection could not occur in an otosclerotic ear. The advancing hearing loss in a patient with otosclerosis with scarred drums was deemed due to a "chronic progressive adhesive deafness" because the adhesions grew tougher and less flexible with advancing years.

Not only did these mixed losses prove puzzling but even the pure conductive and pure perceptive losses could not be properly classified. This is not surprising when one considers the diagnostic methods available in the mid-1920's. Even today, we are only beginning to appreciate the difference between a lesion of the end organ and nerve involvement, and we had to wait till recruitment tests had become popular and testing of hearing by monitored speech had come into its own before this difference could be assayed. It is interesting to note that recruitment was recognized and described by Dr. Fowler Sr. many years before it was suggested that this phenomenon might be useful in differentiating Ménière's syndrome from acoustic neuroma. In the mid-1920's it would have taken considerable temerity to classify as a pure perceptive loss an audiogram which showed a greater loss in the low tones than in the higher frequencies.

We were resigned, in my beginning days, to the fact that we could do nothing with irreversible losses—both perceptive and conductive. We awaited termination of acute suppuration with the hope that, in each instance, it would leave no hearing loss in its wake. Fortunately, more often than not, it left none. Even the lowly and remediable secretory otitis was frequently missed and thus went untreated. We stood in awe of hearing losses. We suggested hearing aids of the kind then available and hoped they would be helpful.

If this sounds derogatory, it is not meant to be so. I have a profound respect for my seniors in otolaryngology. They taught me so much that I shall be forever grateful for their efforts. They were artists in the techniques of the day, and they were responsible for saving many lives. The curtailment of infection is probably the major cause for the difference between my beginning days and 1957.

Have we not come a long way? It is almost right to say that no case of conductive hearing loss is without possible help by surgery. This all began when our honorary chairman, Dr. Julius Lempert, so perfected the fenestration operation that he could get lasting hearing improvement from it. Further, he could teach its technique to others so they could do likewise. It is only natural that surgery for congenital atresia, tympanoplasty, and mobilization of the stapes followed. It is interesting, too, to speculate that the surgical triumphs are successful to the degree that they are not only because of the perfection of these techniques by their authors but also because the after care is benefited and largely con-

---

Chairman's address, read before the Section on Laryngology, Otology, and Rhinology at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

trolled by the use of the antibiotics. It is logical to assume that further advances will be made which will be built on the background of these techniques. The other day, I was faced with a dilemma. A patient on whom a radical mastoidectomy had been done, with a resulting major hearing loss in that ear, presented himself with a cholesteatoma behind the drum in the opposite ear. With use of the endaural technique and the principal behind the mobilization exposure, a cholesteatoma which extended from the antrum to the floor of the tympanum was removed without disturbance of the ossicles (which were intact). The drum and the cutaneous canal wall were replaced. The cavity was closed by sutures as in a simple endaural mastoidectomy, and two weeks later a hearing test revealed normal hearing in this ear. Five years ago a radical mastoidectomy would have been done, with a handicapping hearing loss as a probable result. Such surgery is possible because some have blazed the trail with techniques which were unknown in my beginning days.

Prophecies for the Future

I have just said that it is almost right to say that no case of conductive hearing loss is without possible benefit of surgery. What of the future of perceptive losses? I believe we will see fewer of these in the future than we have in the past. This is not because I believe a cure is just around the corner. Parenthetically, a cure looks impossible now, but so did one for otitic meningitis 20 years ago. I have seen too many medical miracles in my lifetime to state categorically we will never have a cure for perceptive hearing losses. But a cure is not on the horizon now, so why do I say I think there will be fewer perceptive losses in the future? I think it will come about by prevention. Let me mention a few ways through which this may come to pass.

Among several causes, four come to my mind at the moment which have crippled many persons in the past and which may be on the way out; some of them actually are. The first of these are the conditions which cause a child to be born with a congenital hearing loss. There probably always will be the sporadic case of hearing loss in a newborn child, despite all the preventive measures we institute. We do not know the cause in each instance now, but we are gradually learning some of them. We now know that the severe jaundice which sometimes follows an Rh-negative pregnancy may cause a severe hearing loss. We also know that a baby who is a so-called blue baby in the first week or so of life may suffer a hearing loss because not enough oxygen is in the blood in these first few days to give adequate nourishment to the ears so they can live to the full. The result is that part of the ear dies and never functions again. We know, too, that rubella suffered by a mother in the first trimester of her pregnancy may result in the birth of a child with a severe hearing handicap. These are three conditions which we know can cause a congenital hearing loss.

There is hope that the appropriate management of an Rh-negative pregnancy may prevent the occurrence of marked jaundice in the baby, who otherwise may have a severe hearing loss. The proper administration of oxygen or the employment of other necessary remedial measures to a blue baby may prevent damage to hearing. Should abortion be induced in a young woman who has had rubella in her first three months of pregnancy? This question has been raised. There are arguments which say no, particularly religious ones. Will an appropriate serum promptly administered be the answer? Here are possible preventive measures which were not in existence a mere 10 years ago. Here is hope that there will be fewer congenitally deaf babies in the future.

A frequent cause of hearing loss in later life is that which is due to the fact that the ear does not have its proper blood supply, i. e., the loss that follows arteriosclerosis or atherosclerosis. Some very exciting research is under way, the final conclusions of which are not yet available, which shows that it may well be that proper medication and diet will prevent atherosclerosis and thus eliminate the hearing loss due to poor blood supply to the ears. To prevent this type of loss, a physician must be aware of the fact that the individual has poor vascular supply to the ear and that because of this a subsequent hearing loss may occur, or, if a loss is already present, an additional loss will occur if remedial measures are not instituted. This is preventive medicine of the highest order. That all hearing loss due to this cause may be prevented is not a prediction. Research only suggests that it may be, but this is certainly exciting. It is particularly so, because very often in this type of hearing loss a hearing aid has no value.

A third cause of hearing loss which may diminish is that which is due to allergy. Allergic sensitivity sometimes includes the ear. Occasionally, this causes a sudden severe loss. More frequently, however, as a result of repeated minimal allergic episodes throughout life, in later years there is a fair degree of the loss of hearing due to gradual degeneration of the nerve of hearing. Many children, as well as adults, today are under allergic management, and, because of this, I predict that in the future we will see much less of this type of hearing loss than we see today. For some of the adults, allergic management has been instituted too late to prevent a loss. The great hope is with the children.

Lastly, I think of the loss of hearing that is due to exposure to industrial noise. To affect hearing, industrial noise must be very loud, and ears must be exposed to it over a period of years. Hearing loss is found frequently in many workers in the heavy industries. Fortunately, the ears of all workers are not equally sensitive. Some are resistant to noise exposure, but the number of men who are riveters, chippers, and drop forge hammer workers and who have a considerable hearing loss due to exposure to the noise of their occupation totals more than one likes to think. This has been recognized as a threat to hearing for more than 100 years. Fosbrooke, as long ago as 1831, wrote about this kind of hearing loss, but, unfortunately, very little was done about its prevention until recently.

Industry was unwilling to take steps to correct this situation because there had been no claims for compensation for industrial hearing loss. Apparently, management felt that to institute corrective measures would awaken labor to the fact that this was a compensable condition. Management evidently feared a flood of claims. Their fears were correct, because the flood of claims has begun. Awakened by the activities of the Committee on Noise in Industry of the American Academy of Ophthalmology and Otolaryngology, industrial management, union leaders, and insurance officials are now very cognizant of this industrial hazard. Preventive measures in the form of reduction of noise at its source and the prevention of damage to the ears by the wearing of ear defenders if the noise is not reducible to a safe limit are fast becoming the order of the day. Some really significant changes in the picture are just around the corner.

If these four causes of hearing loss are even partly eliminated, the amount of human suffering which can be eliminated is incalculable. There is promise that this may be so in each one of these instances.

In relating to you the techniques now available for use in helping those who have hearing handicaps, which our forebears did not have, and the very exciting news that some hearing losses may never occur at all, I do not mean to say that the problem of hearing losses will disappear. We will undoubtedly have a good deal of it with which we must cope for the rest of our lives, but just as today we look askance at one who condemns a young child to a life of limited usefulness by saying "It is deaf and dumb" and refuses to do anything about it, some of our descendants will probably look back on this day and wonder why we had so much hearing loss, why we managed it so poorly, and why we allowed it to become such a handicap. It is thrilling to take these peeks into the future and to be a part of the present-day advances in alleviating conductive losses. The contemplation of this should make us all wish to double our efforts. There is every promise that there will be many fewer individuals with hearing handicaps. It is exciting to be a part of this glorious picture.

REDUCTION IN ELEVATED BLOOD CHOLESTEROL LEVELS BY LARGE DOSES OF NICOTINIC ACID

PRELIMINARY REPORT

William B. Parsons Jr., M.D.
and
John H. Flinn, M.D., Madison, Wis.

Prompt and sustained reduction of blood cholesterol levels was obtained in nearly all of the hypercholesteremic patients who received large doses of nicotinic acid. Daily doses higher than 3 Gm. of nicotinic acid were required in more than 50% of the patients and in some cases 6 Gm. daily were needed to consistently reduce the blood cholesterol level. No dietary restrictions were imposed in this study. The mechanism by which nicotinic acid produces the observed changes in blood lipids remains obscure.

Previous studies by one of us (W. B. P.) and associates at the Mayo Clinic showed that significant reductions of levels of blood cholesterol and total lipids followed administration of large doses of nicotinic acid (niacin) in persons with hypercholesteremia.[1] The ratio of beta-lipoprotein cholesterol to alpha$_1$-lipoprotein cholesterol was also reduced by therapy with nicotinic acid. Phospholipids remained essentially unchanged, resulting in lowering of the cholesterol-phospholipid ratio. Substitution of a placebo resulted in return of cholesterol levels and the lipoprotein fractions to pretreatment levels. Further administration of nicotinic acid re-

---

From the Department of Internal Medicine, Jackson Clinic.

ed in reduction of the lipid constituents similar to initial response.[1b] The effect of nicotinamide (ni- amide) was not studied.

The present study was undertaken to confirm the ults of the Rochester group, to obtain further expe- ice with different doses of nicotinic acid, and to gin to evaluate the effect of nicotinamide on blood ids. Blood cholesterol levels only were determined, itting the total lipid and lipoprotein determina- ns, which had varied in the same direction and in out the same magnitude as the cholesterol levels in e earlier studies.[1] The results are so impressive that consider a preliminary report to be justified at this ne.

Material and Methods

Patients were selected for study if the blood choles- ol level was consistently higher than 260 mg. per 0 cc. on at least two determinations before therapy. ie average pretreatment level was 270 mg. per 100 . or higher in all patients.

Cholesterol determinations had originally been per- med in these patients for a variety of reasons. Nine tients had survived myocardial infarctions. Three hers suffered from angina pectoris, and two patients id arteriosclerosis obliterans with claudication. Two tients had survived cerebral infarctions. Two had abetes mellitus. Xanthelasma of the eyelids had been oted in five patients, xanthoma tendinosum in one, nd premature arcus senilis in two. Five patients gave history of hypercholesteremia and/or atheroscle- otic disease in members of their families but showed o evidence of these clinical states themselves.

Nicotinic acid was administered initially in doses of Gm. daily in the form of capsules each containing 00 mg. Two capsules were given three times daily fter meals to minimize side-effects. This dose was con- inued for 12 weeks in all patients. Then, if the blood holesterol was normal (less than 250 mg. per 100 cc.), he same dose was continued, or, in a few patients, a naintenance dose of 1.5 Gm. per day was tried. In patients whose cholesterol levels remained above normal after 12 weeks, the daily dose was increased to 4.5 Gm. and later to 6.0 Gm. in some cases, depending on the response. After 30 weeks of therapy with nicotinic acid, nicotinamide was substituted in a dose equal to the most effective dose of nicotinic acid.

All patients were urged to continue eating exactly as they had before the study, so that the only variable introduced was the administration of nicotinic acid. Except in one patient (case 9) on a low-fat diet and two diabetic patients (cases 2 and 14) on special diets, all patients can be considered to have been eating an average American diet.

Blood samples were drawn at two-week intervals for cholesterol determinations by the method of Drekter.[2] Determinations of sulfobromophthalein (bromsulfalein) clearance and blood nonprotein nitrogen and urinalysis were performed after 8 to 32 weeks of therapy in 19 patients.

Results

Changes in Cholesterol Levels.—Twenty-four patients have thus far been followed for 12 weeks or longer. Of these, eight patients (group 1) have completed 30 weeks of therapy with nicotinic acid and 4 to 12 weeks of nicotinamide, permitting some preliminary observations regarding the latter drug. The remaining 16 patients (group 2) have completed 12 to 30 weeks of therapy with nicotinic acid.

Table 1 shows mean cholesterol levels for both groups of patients at two-week intervals. The prompt reduction effected by nicotinic acid is shown in the mean decrease of 56 mg. per 100 cc. in the first two weeks of therapy. The effect of the initial dose (3 Gm. daily) is shown by a mean reduction of 68 mg. per 100 cc. in group 1 and 59 mg. per 100 cc. in group 2 in the first 12 weeks. The effect of larger doses is shown by a further mean reduction of 14 mg. per 100 cc. in the subsequent 18 weeks in group 1.

TABLE 2.—*Average Cholesterol Levels During Therapy with Nicotinic Acid and Nicotinamide (Group 1)*

		Av. Cholesterol Levels, Mg. per 100 Cc.			
Case No	Age and Sex	Before Therapy	0-12 Wks	12-30 Wks	Nicotinamide Therapy
1	56 M	480	291	284	342
2	54, F	305	241	252	280
3	44, F	308	241	265	284
4	53, F	337	231	249	349
5	56, M	272	276	246	301
6	38, F	315	269	260	318
7	61, M	298	269	219	326
8	50, F	360	299	292	254
Av		334	267	258	319

As shown in table 1, the eight patients of group 1 showed a reduction in mean cholesterol level of 64 mg. per 100 cc. in the first two weeks of therapy, from 334 mg. to 270 mg. per 100 cc. At the end of 30 weeks of therapy, the mean cholesterol level had been reduced further to 252 mg. per 100 cc.

In the eight patients of group 1, the plasma cholesterol level after 12 weeks of therapy (3 Gm. of nicotinic acid daily) was normal (less than 250 mg. per 100 cc.) in three, significantly reduced (40 mg. per 100 cc. or more), but not to normal in two others, and not significantly reduced below the average pretreatment level in three. At the end of 30 weeks of therapy, normal values were found in six of the eight patients. One of the other patients showed significant reduction but not to normal, and no significant reduction had occurred in one.

Average values for these patients in each period of treatment are shown in table 2. The effect of doses larger than 3 Gm. daily (in all except cases 2 and 4) is reflected in the lower averages for the 12-to-30-week period as well as by the larger number which had reached normal levels by the end of 30 weeks. The mean levels for the 12-to-30-week period might have been lower except for the use of decreased doses of nicotinic acid (1.5 Gm. daily) in two patients. Cases 3 and 4 were given daily doses of 1.5 Gm. for eight weeks (from the 12th through the 20th week) with return of cholesterol levels to higher values in both instances, necessitating resumption of the original dose. One patient (case 2) differed from all others in the study in that a daily dose of 1.5 Gm. of nicotinic acid was used throughout the first 24 weeks, after which nicotinamide was administered.

* No value given for further therapy if less than four weeks.

The 16 patients of group 2 showed reduction in mean cholesterol level of 51 mg. per 100 cc. in the first two weeks of therapy, from 320 to 269 mg. per 100 cc. (table 1). The mean cholesterol level was further reduced to 261 mg. per 100 cc. by the end of 12 weeks of therapy.

In the 16 patients of group 2, the plasma cholesterol level after 12 weeks of therapy was normal in 6 patients, significantly reduced but not to normal in 4 others, and not significantly reduced in 6. Further therapy in 14 of these patients included the use doses larger than 3 Gm. daily in 9 patients (case 12, 14, 16, 17, 18, 20, 21, and 22). The last cholest determination gave a normal result in seven patie significant reduction but not to normal in two, and significant reduction in seven. Average values for patients of group 2 in each period of therapy shown in table 3.

The effect of doses larger than 3 Gm. of nicoti acid per day in the five patients who eventually ceived 6 Gm. daily is shown in table 4. In all, incre doses were used in 15 patients whose cholesterol le were higher than normal after 12 weeks of therapy these, only two patients had consistently normal ch terol levels after daily doses of 4.5 Gm. Of the patients who have taken 6 Gm. per day, choles levels reached normal in all except one (case 8) were consistently normal in three (cases 5, 6, an Based on these results, one might predict simila provement in the seven patients who have fail respond to doses of 4.5 Gm. daily and who will receive larger doses as the study continues.

Administration of nicotinamide to the patien group 1 resulted in prompt increases of chole levels to the pretreatment range (table 2). Th sult occurred despite the use of doses equal t dosage of nicotinic acid which had produced the satisfactory response.

Side-reactions.—The absence of serious side tions, noted by the Mayo Clinic group, was confir Nearly all patients experienced a subjective and tive flush, which occurred briefly after each dose nicotinic acid for the first one to seven days of admin tration. This phenomenon decreased in intensity af the first day and had almost invariably subsided by t end of the first week, with an average duration three or four days. After the first week about half the patients reported that the first dose of the d occasionally caused flushing, which was, however, severe. This occurrence seems related to the size of t meal which preceded the ingestion of nicotinic a Pruritus frequently accompanied the flush and often persisted a few days longer. Urticaria occurred ver briefly in two patients and did not interfere with the apy. Three patients (not included in this series stopped taking the drug because of side-reactions: c after five days because of the flush, another after t

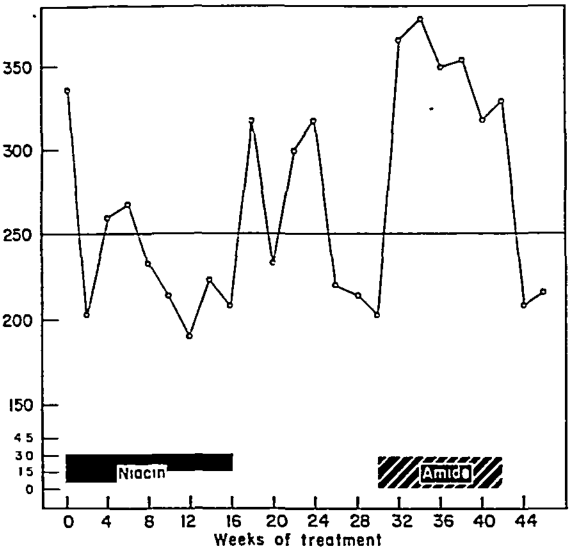
ks because of irritable bowel symptoms, and the d after several weeks because of dryness of the and blurring of vision with no objective findings n examined by an ophthalmologist before and after ose of nicotinic acid. No side-reactions were ob- ed in patients taking nicotinamide.

ulfobromophthalein tests of liver function, deter- ations of blood nonprotein nitrogen levels, and alyses revealed no abnormality in 19 patients after 32 weeks of therapy.



g. 1 (case 4).—Illustration of reduction of blood cholesterol s by administration of 3 Gm. of nicotinic acid (niacin) , return to elevated levels during the use of 1.5 Gm. of inic acid daily, reduction to normal levels when a daily of 3 Gm. of nicotinic acid was resumed, return to ele- d levels when nicotinamide (niacinamide) was substituted, reduction to normal levels when use of nicotinic acid was n resumed.

Comment

rompt and sustained reduction of blood choles- l levels after large doses of nicotinic acid in nearly of the patients studied confirms the previously re- ted results of the Mayo Clinic group.[1] The greater uction in cholesterol levels and larger percentage of es showing reduction to normal values in our series be attributed to more liberal use of doses of 4.5 or m. per day. As further experience has been ob- ed, it has become apparent that 50 to 70% of ients require doses of this order to reduce choles- l levels to normal. It also seems clearly established t continuous therapy at the same dosage is neces- y to maintain the reduced levels, since substitution a placebo or of nicotinamide resulted in prompt urn of blood cholesterol to the pretreatment range values. With very few exceptions, a dose of 1.5 Gm. nicotinic acid per day has also proved to be ineffec- e or to give suboptimal results.

Figures 1, 2, and 3 show typical cases which illustrate individual variations in response to the various doses of nicotinic acid and the lack of effect of nicotinamide. Figure 1 shows the prompt reduction to normal cholesterol levels in case 4 on the initial dose of 3 Gm. daily. When the dose was reduced to 1.5 Gm. daily, the cholesterol levels again rose. Resumption of the original dose resulted in reduction to normal levels again. When nicotinamide was substituted at the end of 30 weeks, blood cholesterol levels rose to values as high as those observed before treatment. After 12 weeks of administration of nicotinamide, nicotinic acid was again given in the original dose, followed by prompt reduction of blood cholesterol level to normal.

Figure 2 shows the failure of the patient in case 7 to respond to the initial dose of 3 Gm. per day but reduction to consistently normal cholesterol levels after use of 4.5 Gm. daily. Substitution of nicotinamide in the same dose was followed by an abrupt rise in cholesterol levels to well above the normal range. When administration of nicotinic acid was resumed, blood cholesterol levels fell to normal and have remained consistently normal.

Figure 3 shows the failure of the patient in case 6 to respond to doses of 3 Gm. daily or 4.5 Gm. daily but reduction to consistently normal cholesterol levels after

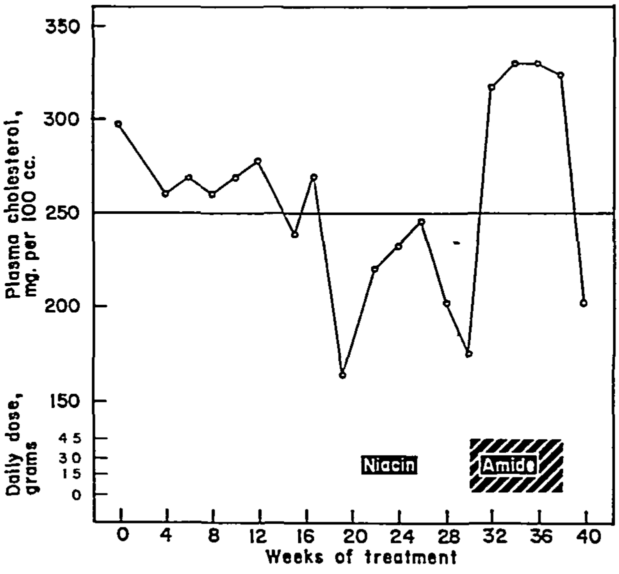


Fig. 2 (case 7).—Illustration of reduction of blood cholesterol levels to normal by administration of 4.5 Gm. of nicotinic acid (niacin) daily, return to elevated levels when nicotinamide (niacinamide) was substituted, and reduction to normal levels when use of nicotinic acid was resumed.

use of 6 Gm. daily. When nicotinamide was substituted in equal dosage, cholesterol levels returned to values as high as those observed before treatment.

The rapid disappearance of the flush which nicotinic acid produces and the absence of other significant side-reactions or toxic effects in the experience to date suggests that this method is practical for clinical use.

Since no dietary restrictions were imposed either in the present study or in the Mayo Clinic series, it is apparent that nicotinic acid reduces cholesterol and beta-lipoprotein cholesterol levels in spite of the use of an average American diet by persons with hypercholesteremia.

The mechanism by which nicotinic acid produces the observed changes in blood lipids remains obscure. The apparent failure of nicotinamide, which had an effect similar to that of the placebo employed by the Rochester group, may provide a clue to the mechanism of action because of the slight chemical difference between the two drugs. These observations may, in fact, open a new avenue of investigation regarding the mechanism which establishes the total blood cholesterol and its several lipoprotein fractions at normal or abnormal levels. The lack of cholesterol-reducing effect of nicotinamide agrees with the observations of Altschul and associates.[3]

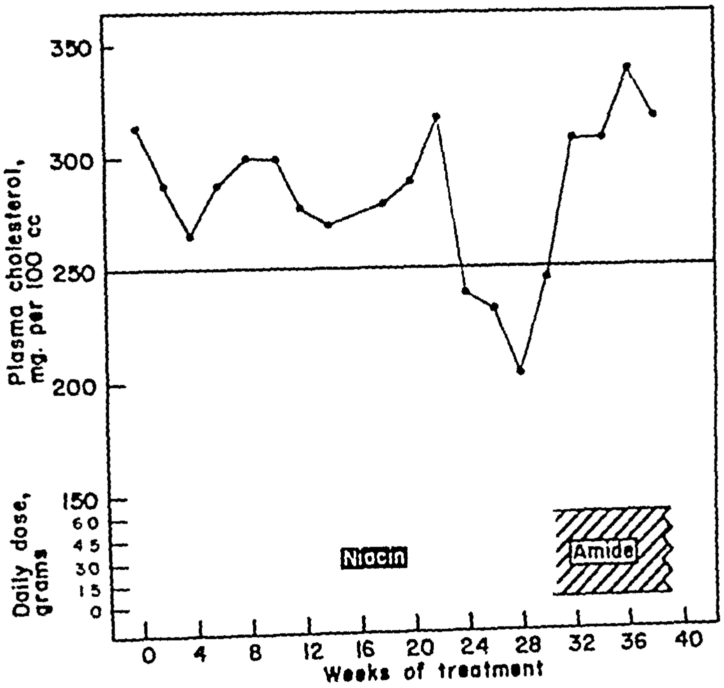

Fig. 3.—Illustration of the reduction of blood cholesterol levels to normal by administration of 6 Gm. of nicotinic acid (niacin) daily, with the return to elevated levels when nicotinamide (niacinamide) was substituted.

The accumulated experience in the Rochester and Madison series indicates, we believe, that nicotinic acid is the most effective and practical agent yet introduced for reduction of elevated levels of blood cholesterol and beta-lipoprotein cholesterol. The observed changes in blood lipids are those which have been the objective of many therapeutic programs because of the increased incidence of atherosclerosis in individuals with hypercholesteremia and elevated ratios of beta-lipoprotein to alpha$_1$-lipoprotein cholesterol. However, in spite of the well-known statistical relationship, we do not mean to imply that these changes will necessarily prevent atherosclerosis or arrest its progress. Evidence of such benefit can be obtained only by treating a large number of patients for r years and comparing the results with an untr control group. This study is now in progress. It sh be mentioned, however, that Altschul's studies rabbits showed inhibition or prevention of ather formation in animals fed nicotinic acid and cholest in comparison to a control group fed cholesterol w out nicotinic acid.[3b]

Summary

Administration of nicotinic acid (niacin) orally large doses (3 to 6 Gm. daily) to 24 patients w hypercholesteremia resulted in significant reduction blood cholesterol levels in 16 (66.7%). Normal le were attained in 6 of 8 patients followed for 30 we or longer and in 7 of 16 additional patients follow for at least 12 weeks.

Doses higher than 3 Gm. of nicotinic acid da were required in more than 50% of patients. Sig reduction in blood cholesterol occurred with doses 6 Gm. daily in four of five patients whose levels h remained above normal after smaller doses, sugge ing the possibility of future improvement in sev additional patients who have thus far failed to respo to a daily dose of 4.5 Gm.

Substitution of nicotinamide in equal dosage af 30 weeks of therapy with nicotinic acid in eight p tients was followed by prompt return of blood chol terol to pretreatment levels in every instance.

Flushing and pruritus, which occur after ingest of nicotinic acid, subsided within the first week therapy in nearly all cases. No serious side-r or toxic effects have been observed which can attributed to nicotinic acid. Nicotinic acid proved be effective in lowering cholesterol levels despite tinuation of the patients' customary diets.

The capsules of nicotinic acid were supplied by the Eli Li Company. Each capsule contained 0.450 Gm. of nicotinic ac and 0.050 Gm. of lactose. For ease of calculation, the approx mation of 500 mg. of nicotinic acid per capsule was used.

CLINICAL NOTES

ACCIDENTAL INGESTION OF A TOXIC DOSE OF CHLORAMBUCIL

REPORT OF A CASE IN A CHILD

Sorrell Wolfson, M.D.
and
Mary B. Olney, M.D., San Francisco

Chlorambucil [p-(di-2 chloroethyl) aminophenyl- tyric acid, CB 1348], a water-soluble aromatic nitro- n mustard, was developed by Haddow and his as- ciates[1] at the Chester Beatty Research Institute in ndon and has recently been used in the treatment patients with malignant lymphoma and leukemia.[2] The purpose of this paper is to report the clinical d hematological effects observed in a child from the cidental ingestion of an overwhelming dose of this ally given nitrogen mustard. A review of the litera- re has failed to reveal a previous report of this type.

Report of a Case

A 2½-year-old male accidentally ingested approximately 35 mg. (5 mg. per kilogram of body weight) chlorambucil tab- s while visiting an uncle who had been taking this experi- ental drug for an inoperable sarcoma. Three hours after this cident occurred, the child became lethargic and vomited. e grew progressively more unresponsive, and five hours after e ingestion he lapsed into unconsciousness, with generalized and mal seizures which were characterized by tonoclonic vements of all extremities, eyes rolled back in his head, wel and bladder incontinence, and foaming at the mouth. He s brought to the emergency hospital where he was lavaged th water without recovery of any of the tablets. He was mediately referred to the pediatric ward at San Francisco unty Hospital in status epilepticus. Convulsions were con- lled with intravenous administration of 150 mg. of sodium ytal and 2 cc. of paraldehyde per rectum. Intravenous ther- y with fluids was started, and 5 oz. (141.75 Gm.) of mag- sium citrate was given as a cathartic.

There was no family history of convulsive seizures, and the tient had experienced none prior to this admission. Physical amination at the time of hospitalization revealed a 2½-year- d boy who was comatose and dehydrated, weighing 14 kg. 31 lb.) with rectal temperature of 99 F (37 C), pulse 96 per inute, respiration 20 per minute, and blood pressure 108/72 m. Hg. There were no positive findings in the head, neck, ngs, or heart. Abdominal and rectal examinations also were remarkable.

Neurological examination revealed the deep tendon reflexes be hyperactive but equal bilaterally. Babinski reflex was esent bilaterally; however, Kernig, Brudzinski, and Hoffmann gns were absent. The cranial nerves were intact. The sensori- m was cloudy. Muscle strength and coordination were difficult evaluate because of the patient's comatose state.

During the first 24 hours after admission, the patient re- ained comatose or semicomatose, during which time he had o grand mal seizures, lasting 30 seconds each, and several bouts of vomiting of clear fluid. He was given fluids intravenously, oxygen nasally, sodium phenobarbital (15 mg. twice, intravenously) and prophylactic procaine penicillin G (300,000 units).

On the second hospital day, the patient improved markedly, with complete disappearance of symptoms and signs. Administration of oxygen nasally was discontinued. After 12 hours on therapy of clear liquids, he was put on a high-protein diet with multivitamins (Tri-vi-sol, 0.6 cc. twice a day). Phenobarbital (15 mg. twice a day) was administered for four days, and then discontinued.

His 43-day hospital course was complicated by intermittent idiopathic elevations of temperature, varying from 101 to 103.4 F (38.33 to 39.66 C) (rectally). Because of this, the penicillin therapy was discontinued after 18 days and tetracycline therapy (400 mg. a day) was begun and continued for 16 days. Rubeola developed on the 36th hospital day in spite of a preventive dose of gamma globulin (3 cc.) on the 19th hospital day. He recovered from the rubeola without sequelae. His weight remained unchanged throughout his period of hospitalization.

Routine urinalysis on admission was unremarkable. However, about an hour after he had been catheterized on the first hospital day a urine specimen contained a trace of albumin and 10 red blood cells per high-power field. Repeated urinalyses throughout the hospital stay were all normal.

Repeat guaiac examinations of the stool were negative for blood. Liver and kidney function studies were all within normal limits throughout his hospital stay. The hemogram on admission revealed a slight hemoconcentration and polymorphonuclear neutrophil leukocytosis. This could be explained by his state of dehydration and convulsive disorder. On the fourth day after drug ingestion, a marked leukopenia with depression of both the lymphocytes and polymorphonuclear neutrophils was observed. There was a lymphocytosis on the 12th day, with a return to the normal level on the 27th day. The polymorphonuclear cells showed a gradual return to the normal level by the 27th hospital day. The red blood cells and hemoglobin level remained within the range of normal throughout the hospital course (see figure). The platelets appeared adequate on peripheral blood smears and no abnormalities of bleeding or clotting were observed clinically. The blood picture became complicated with the development of rubeola on the 36th hospital day, at which time his hemogram showed the typical measles reaction, i. e., leukopenia with lymphocytosis, with a return to normal after his recovery.

Bone marrow examinations were made at weekly intervals and were all within normal limits. After discharge from the hospital, the patient was followed intermittently in the outpatient clinic. He has been completely asymptomatic. A psychometric examination revealed the child to have an intelligence quotient of 89 according to the Stanford-Binet, Form L, which the psychologist interpreted as low normal intelligence. An

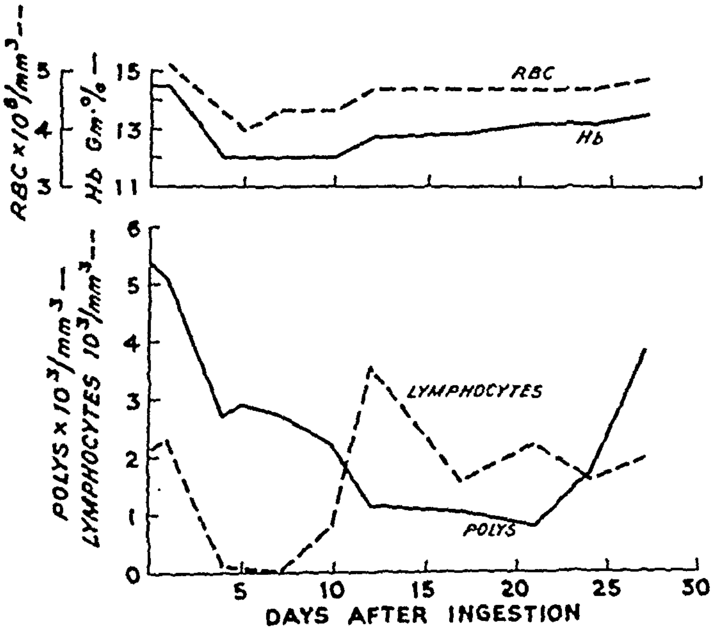
---

From the Department of Pediatrics, University of California edical Center.

electroencephalogram was interpreted as being within normal limits. Follow-up hemograms have revealed normal blood cell counts.

Comment

Galton and others[2a] reported that a dose of 0.1 to 0.2 mg. per kilogram per day of chlorambucil for three to six weeks was effective in the treatment of patients with malignant lymphoma. These workers, as well as Altman and others[2c] who worked with leukemia patients, observed that the drug produced an immediate lymphopenia and delayed neutropenia which persisted during the period of administration and promptly disappeared when the drug was withdrawn. With therapeutic doses, they noted relatively few toxic effects except for nausea and vomiting. Galton and others[2a] found that patients who received a total dose approaching 6.5 mg. per kilogram risked possible irreversible bone marrow damage. They concluded that the hematological effects produced by this drug were related to the dosage, and the dosage likely to cause bone marrow damage is well beyond the therapeutic range.



Blood response to oral ingestion of nitrogen mustard (chlorambucil).

Elson[3] working with rats which were given a single intraperitoneal dose of 12.5 mg. per kilogram of chlorambucil observed a transient lymphopenia and neutropenia with rapid return to normal of both the bone marrow and blood picture. This case is similar. However, the patient did not develop obvious bone marrow depression over the 24-week period after ingestion, and the red blood cell count, hemoglobin level, and platelet count remained essentially unaffected by the drug.

Overdosage with this drug produced vomiting, lethargy, convulsions, and a comatose state in an otherwise normal child. Similar effects have been observed by Boyland[4] and Rutenburg and others animals receiving toxic doses of other alkylating cy toxic agents. The previous investigators[6] have reported any neurotoxic effects of chlorambucil.

Our patient exhibited intermittent episodes of fe which were believed to be related to the prophyl antibiotics. However, it is possible that this ag might have temporarily affected the thermoregula center. Careful follow-up of this child will be c tinued to determine whether there is any detrimen long-term effect of this drug.

Summary

A 2½-year-old child accidentally ingested a m sive dose of chlorambucil (CB 1348) (5 mg. p kilogram of body weight, total 70 mg.). This p tient showed relatively few toxic effects. The p cipal reaction was neurotoxic, characterized by convulsive disorder and comatose state that w readily corrected over a relatively short period time. The neutrophils and lymphocytes were te porarily depressed during the first 27 days af ingestion, but no recognizable bone marrow dep sion was observed. The red blood cell series, he globin level, and platelet counts remained essenti unaffected by this drug. Chlorambucil caused apparent disturbance to the renal and hepatic fu tions, or to other systems of the body.

We should like to express our appreciation to Dr. R Wallerstein for interpretation of the bone marrow smears to Dr. Edward H. Strisower for his study of the peripl blood smears.

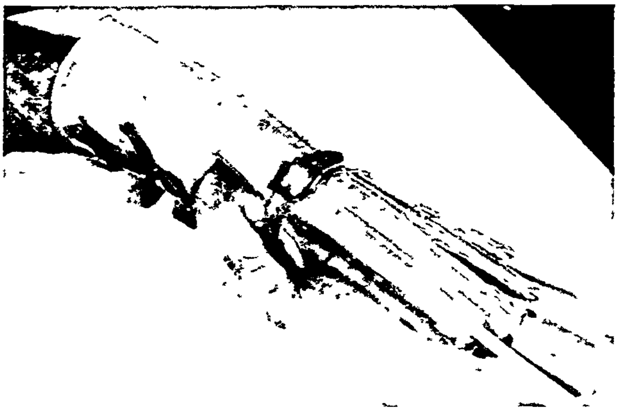
A GLOVE-TYPE EXTENSION HAND SPLINT

Frederick W. S. Modern, M.D., George V. Devins, B.A., R.C.T.
and
John C. Russey, Cert. Prost. Orthot., Long Beach, Calif.

A glove-type extension hand splint has been under vestigation in the Physical Medicine and Rehabilita- n Service of the Veterans Administration Hospital, ng Beach, Calif. After numerous modifications we ived at the following model. We have constructed a ve in which the fingers of the glove are replaced by gerlings which permit each finger to be secured dividually. The fingerling begins just proximal to the st interphalangeal joint and ends beyond the fin- rtip. The fingerling is attached to a tongue of leather nich forms part of the body of the glove.

The back of the glove carries a leather tunnel which ntinues into the tongue of each fingerling. Metal ays are inserted into each tunnel, as many as nec- sary to overcome the flexor spasm or contracture ithout causing the patient undue discomfort. A rap at the metacarpophalangeal level prevents e fingers withdrawing from the fingerlings during ute spasm. The front of the glove is split and is rovided with straps to make the application of e glove easier.

The advantages of this type of extension splint are that it is easily applied, is light weight, has good cosmetic effect, and is completely adaptable to the amount of spasm and/or contracture of each individual finger and that nearly all patients are able to put on and take off the splint without assistance.



Dorsal aspect of splint. Note tunnels with stays in place. Number of stays depends on resistance to be overcome and tolerance of patient.

From the Physical Medicine and Rehabilitation Service and e Brace Shop, Veterans Administration Hospital.

SPECIAL ARTICLE

THE U. S. ARMY MEDICAL DEPARTMENT IN WORLD WAR II

THE HISTORY OF THE HISTORY

Col. John B. Coates Jr. (MC), U. S. Army

When Brig. Gen. Frank W. Weed, M. C., had nished his labors as editor of the history of the United States Army Medical Department in World War I, he wrote a most excellent and readable account f his experience.[1] In it, he remarked that if the personnel responsible for writing the history of the War f the Rebellion had been available at the time the history of World War I was written, and if they had kept abreast of the times, the latter history would have been produced much more expeditiously in respect to quality, time, and money. Even if they had not kept abreast of the times, they would have been very useful indeed. In fact, almost the only assumption in which General Weed was wrong was contained in his sound advice—which was not followed—that a directive, with the force of Army Regulations, should be prepared to provide for a continuing historical survey against a future war, though "many years may elapse before we become involved in a war, whose magnitude would warrant having a medical and surgical history for it comparable in size either for the Civil War or for the World War." He wrote these words in 1929, and it was only 12 years later that the United States entered World War II.

Director, the Historical Unit, United States Army Medical ervice, Walter Reed Army Medical Center, and Editor-in-Chief of "Medical Department, United States Army in World War II."

Read in summary before the annual meeting of the Society f Medical Consultants to the Armed Forces, Washington, D. C., Nov. 26, 1956.

The history of the U. S. Army Medical Department in World War II is far from completion, and the time to write the definitive history of how it was written has not yet arrived. The story was, however, ably begun by Brig. Gen. Albert G. Love, M. C., U. S. Army (Ret.), first Director of the Historical Division when it was revived in the Office of the Surgeon General in 1941.[2] Another report was made in 1954 by the fourth Director of the Division, the late Col. Calvin H. Goddard, M. C., U. S. Army (Ret.).[3] The present communication is a further progress report.

Historical Note

It is almost exactly a century ago that medicomilitary history came into existence, with the publication, in 1858, an incredible two years after the end of hostilities, of a history of the Crimean War. That two-volume work was conceived by Andrew Smith, Director General, British Army Medical Service, at the very beginning of that war, when he found that nothing was available from previous wars to aid him in his gigantic task. As he wrote in his preface to the history: "The doubts and indescribable anxieties which result from the absence of all details calculated to instruct, under existing circumstances, led me early to determine that my successor should, provided I continued in office till the termination of the war, never have to encounter the many difficulties and perplexities which had fallen to my lot."

General Smith implemented his determination most effectively. He preserved all his correspondence and had a descriptive index made of it. He secured analyses of professional documents and reports. By these and other methods, he was able to produce a two-volume history of the Crimean War within two years after it ended, the first volume dealing with medicomilitary matters and the second, published in two parts, dealing with diseases, injuries, and wounds.

When the War of the Rebellion broke out in the United States, these volumes were available to the Medical Department, and their importance and usefulness were attested to by Surgeon (Brevet Lieutenant Colonel) Joseph J. Woodward, to whom was assigned the duty of gathering material for the history of that conflict. One of the first official actions of Brig. Gen. William A. Hammond, then the Surgeon General, had been to recommend to the Secretary of War, in 1861, that a sanitary commission be set up at once, because "we wish to prevent the evils that England and France could only investigate and deplore."

These volumes on the Crimean War, said Surgeon Woodward, in a report to the Surgeon General in 1865, gave direction to Medical Department efforts, even though British troops were fewer than those engaged in the Civil War and the climate in which they served was different. If, as General Weed wrote in 1929, there had existed during the Civil War a dependable record of earlier wars in which the United States had been engaged, epidemics might have been foreseen, even in those prepidemiology days, and diarrheas might have been less than universal. By the end of that co Surgeon Woodward wrote, with real feeling: "A tory becomes one of the most important duties of medical department of the army; a duty the ex of which would be a grave crime against the Ar the United States, and against every citizen wh future wars, volunteers in defense of his country

The Historical Unit, U. S. Army Medical Servi

The Historical Unit, U. S. Army Medical Servi Class II Activity of the Surgeon General, which h one of its functions the preparation of the histo the U. S. Army Medical Department in World W had its genesis in 1917, shortly after the United entered World War I. The Historical Board app by Gen. William C. Gorgas, then the Surgeon Ge consisted of the Librarian of the Army M Library, Director; the Assistant Librarian, Red and a statistician. Its personnel remained during various administrative reorganizations Office of the Surgeon General until its activities with the publication of the final volume of the of World War I in 1929.

General Weed's recommendation for a historical survey, to which reference has already made, was not carried out, and the only formal cal activities of the Medical Department of the during the next several years were limited to annual reports. In August, 1941, when it was o that the United States could not much longer outside of World War II, the Historical Subd (later the Historical Division and still later th torical Unit) of the Administrative Division, Of the Surgeon General, was formally set up by Gen. James C. Magee, then the Surgeon G under the direction of Col. (later Brig. Gen.) G. Love, M. C., U. S. Army (Ret.), who was re to duty for this purpose.

In March, 1942, and again in January, 19 President not only expressed his desire that pr tions should be made at once for recording the of World War II but also made suggestions f plementation of his wishes, including "drawi whatever scholarly talent might be necessary particularly desired that each agency of the g ment should have ready, as soon as possible aft ending of the war, "a good final report that wil up both what was accomplished and how the jo done."

The President's desires were implemented b War Department in a number of ways in 194 thereafter. The committee of "scholarly talent" he had suggested was appointed. Historical o were set up in various bureaus. Historical of were appointed in the Army Ground Forces, Arm Forces, and Services of Supply, under which the O of the Surgeon General then operated. The Histo Section, Army War College, was designated as advisory and coordinating office for these activitie August, 1943, the scope of the proposed history

return to the Medical Department, in spite of)residential direction and blessing upon historical 'ities, General Love, for almost two years, operated 'r grave difficulties, conducting his activities, as he e, "on sufferance" and proceeding most carefully s "not to attract adverse attention." During this)d his office space, and for a time his secretarial tance, were generally provided by other divisions ie Office of the Surgeon General. By slow degrees vas able to build up a staff, in spite of the strict :ime ceiling on personnel and the difficulty of pro- ng personnel who were qualified in performance 'ell as on paper.

he Chief of Staff, Gen. George C. Marshall, mani- :d great interest in the work of the Historical ision, Office of the Assistant Chief of Staff, G-2, as a result, theater, army, corps, and division his- :al teams were organized, to further his desire that history be prepared and published promptly. This ı suggested similar action to General Love, and orical officers representing the Medical Department e eventually appointed for the Alaskan Defense ımand, the Mediterranean (formerly North Afri-) and European Theaters of Operations, and the thwest Pacific Area.

resent Function and Organization of the Historical t.—As the Historical Unit, U. S. Army Medical vice, presently operates, it has a number of func- s. Among them are the following:

Preparation and publication of the history of the lical Department, U. S. Army, in World War II in the Korean conflict, as well as the history of the rvening years.

Planning of, and provision for, the historical :rage of other selected activities of the Army lical Service on a continuing basis.

Preparation and publication of the "Annual ımary of Major Events and Problems, Office of the geon General."

Collection and maintenance of documents and :r essential material for the historical program of Army Medical Service.

Provision of general clinical and administrative :arch and archival services not only for the Surgeon ıeral and branches of his Office and to the Army lical Service at large but also to federal and other 'edited agencies, both military and civilian, to gressional personnel, and to other historians and ters.

Provision of editorial and publication assistance ırmy Medical Service facilities and personnel.

Development and maintenance of liaison and sup- t of medical authorities, institutions, and related sonnel in the United States and friendly nations, rder to promote, attain, and sustain the over-all ectives and activities of the Surgeon General and Army Medical Service.

These very considerable functions are performed by 8 military and 43 civilian personnel. Military personnel include the Director of the Unit, who is a Medical Corps officer and who is Editor-in-Chief of the volumes of the history of the U. S. Army Medical Department in World War II; another Medical Corps officer, who is Associate Editor of the two neuropsychiatric volumes; and six Medical Administrative Corps officers. In addition to an administrative section, there are four other branches, namely, a Research and Archives Branch, a Historians Branch, an Editorial Branch, and a Special Projects Branch.

The Research and Archives Branch deserves a special word. It is interesting that, in his discussion of personnel necessary for a historical project, General Weed mentioned, almost at the top of his list, an experienced archival assistant. Without an adequate filing system, he pointed out, much of the material collected would become inaccessible and could be relocated later only after the expenditure of a totally unnecessary amount of time and effort.

Although the Research and Archives Branch, as such, was not set up in the Historical Unit until April, 1947, General Love took this advice to heart. From the very beginning of his tenure he gave his attention to the collecting, indexing, abstracting, and filing of all available data. He maintained an index of current medicomilitary literature. He established and maintained contact with other historical agencies in the other services, as well as with the Subcommittee on Historical Records, Division of Medical Sciences, National Research Council, of which more will be said later.

General Love's task was not simple. For security reasons, overseas reports and similar data were not always easy to secure. Restrictions on correspondence with theater surgeons and other medical officers overseas became tighter as the war progressed. Documentary material in the Office of the Surgeon General was often hard to pry loose. Much of the secrecy, both overseas and in the Zone of Interior, was, of course, essential. Much of it seemed—and still seems—unnecessary, particularly that which covered plans that had long since been consummated. In spite of every effort to prevent it, some files were destroyed and others were simply lost, the most striking example being the complete disappearance of the medical supply plans for the North African invasion.

In June, 1946, the Research and Archives Branch of the Historical Unit had only 600 linear feet of material. At the present time, it has more than 2,300 linear feet of material filed in 272 four-drawer legal-size storage cabinets. In addition, it can call upon thousands of documents in storage depots elsewhere in the country. The usefulness of this branch goes far beyond this office and other medical organizations of the Department of the Army. As word has spread of what it can accomplish, it has been called upon to supply medical and other data to various other units of the Armed Forces in the United States and overseas, civil departments of the government, members of the medical and related professions, and military and civilian elements of foreign nations. One of its recent tasks has been to supply material requested by the official biographer of Sir Alexander Fleming. The amount available was surprising both in its bulk and its potential usefulness.

Scope and Planning of the Medical History of World War II

For obvious reasons, the medical history of World War II is a far more ambitious undertaking than the medical history of World War I. In May, 1945, when the war in Europe ended, the Medical Department of the Army had the responsibility for the health and medical care of more than 3 million troops in that theater, about 500,000 in the Mediterranean Theater, about 840,000 in the Southwest Pacific under General MacArthur, and another 455,000 in the Pacific Ocean Areas. Each of the 89 Army divisions, practically all of which were deployed overseas and maintained as fighting units, was supported by some 30,000 men in service units. There were 54,000 nurses in the Army Nurse Corps. The result of this gigantic effort was the achievement of the best health record and the lowest case fatality rate for battle wounds and battle injuries experienced by the U. S. Army in its recorded history up to that time. The recording of this experience is a task of real magnitude.

In World War II, as in the Civil War and World War I, preparation for the writing of the history of the Medical Department, as already noted, began early. For this reason, the records of all three wars are more adequate than they would otherwise have been, though in all three there were errors and omissions in the planning and failure to take advantage of all opportunities. General Weed's summary of these errors and failures in World War I is equally applicable to World War II:

1. There was not enough emphasis, he said, to the officers locally concerned, on the necessity for sustained supervision over the local production of material. It would have been a simple matter, for instance, to impress upon first aid men, in the course of their training, that the notations which they made on emergency medical tags were of historical as well as of medical value.

2. It was not made sufficiently clear to the personnel responsible for them that reports required from hospitals and other medical organizations must be detailed. There is no way of securing a final comprehensive picture unless the original picture contains a great deal more than will be used, so that ultimate selection is possible.

3. Forms for collecting special material were not always thought out with sufficient care before they were distributed. Cryptic questions bring cryptic answers, and replies will never be complete unless questions are penetrating, inclusive, and worded with great care. One of the most dangerous implications of form is the inference, by those who fill it out, tha that simple act they have done all that is necessar

4. Another error in the planning of the histori both World Wars was failure to take advantag available opportunities to stress the historical prog and to collect material for it. In World War I, a cellent inspection system existed, both in the U States and overseas, and it could have been util with very little additional effort, to stress the import of collecting and preserving data. It was not so util and there were similar failures in World War II. particular error, it might be added, is no longer made. The historical program is now part of the a of the annual inspection made by the Insp General, Office of the Surgeon General, of milita stallations and organizations under the immediat trol of that office. Furthermore, current Army R tions require that all medical organizations s yearly activity reports, which, after circulation divisions and offices of the Surgeon General, a tained for further reference in the files of the His Unit. The future continuity of the historical pr in the Office of the Surgeon General is thus assu

In World War II, the excellence of telephon radio communications and the speed of combat nated many of the documents which necessarily in earlier wars. Personal diaries were not permi the combat zone, an order which had its dec bad points as well as its good points. Anyway was little time to set down matters of importa they came to pass. It is unfortunate, in retr that various medical officers with experience in fields were not delegated to write up their expe immediately after they occurred. The task Editor-in-Chief of the history of the Medical ment would have been greatly simplified, a history would have been greatly improved, if t been done.

In spite of these deficiencies, available hi sources are extensive. They consist of official re wide range and scope, as well as of individual tives. All of them are used in the medical histo cisely as they would be used in a purely history.

Individual narratives have proved of great ness. Obviously, one needs the experience platoon to describe accurately the experience bigger battle. Personal interviews have also proved value to supplement documents, to compensate their nonexistence, and to supply details which, one reason or another, have been omitted. The medic officer responsible for the blood program in Wo War II, for instance, provided a chapter for the ume on the surgical consultant system in which, in his desire to keep himself in the background, he managed to create the impression that the program had initiated itself and then rolled on, without the help of huma hands. After a day spent with this officer, who had himself initiated the program and kept it rolling, he uently single-handed, a complete and extremely ineresting chapter could be prepared. A similar session with the Consultant in Surgery, Seventh U. S. Army, ow the Assistant Secretary of Defense (Health and Medical), wrought a similar transformation in his hapter by the addition of many details of real inerest which he had modestly omitted.

By these and other methods, an attempt has been made to avoid the deserved criticism of Hanson W. Baldwin, military critic of the *New York Times*, that most writers on military subjects are "as pedestrian as quads right." On the other hand, the interview method becomes of decreasing value and reliability as time passes. That has been pointed out by Kent Roberts Greenfield, Chief Historian for the whole series of volumes on the history of World War II, who was in uniform during the war and who was formerly Professor of History and Chairman of the Department at Johns Hopkins University. In his excellent little book on his philosophy of history and his experiences in his present office,[4] Historian Greenfield quotes Sir Ian Hamilton, who, writing of the Russo-Japanese War, said: "On the actual day of battle, naked truths may be picked up for the asking; on the following morning they have already begun to get into their uniforms."

The proposal made when the Historical Unit was first activated in World War II, that all historical writing be kept current, proved entirely impractical. As General Love has pointed out, its impracticality is shown by the changing point of view, as the war progressed, on many policies, including the local use of sulfonamides and the use of plasma as a substitute for whole blood in shocked casualties.

Changing Plans and Concepts.—In July, 1940, a Subcommittee on Historical Records was set up in the Division of Medical Sciences, National Research Council, with the chief purpose of preparing a history of the wartime medical activities of all branches of the military services as well as of the Public Health Service and certain civilian agencies. The chief of the many reasons why this was not a sound plan was that the majority of the nine volumes planned were to be prepared by civilians. However competent they might be in their specialties—some of them were among the foremost clinicians in the country—the difficulties of their task seemed insuperable. To put it as simply as possible, they had had no part in the medicomilitary experiences they were called upon to relate. They had not been there.

General Love had many misgivings about this method of preparing the history, but he went along with it originally because, as he said quite frankly, he did not originally have "enough prestige to take issue with it." Except that it was modified by the addition to the nine planned clinical volumes of seven other volumes designed to cover the administrative, technical, and tactical activities of the Medical Department, this plan remained in effect until March, 1944. These additional volumes were to be supervised by General Love's office and were to be written by medical officers.

As time passed, however, it became increasingly clear that, in view of the tremendous scope of the war, the professional experience gained in it, and the multiple clinical and medicomilitary problems involved, it would be entirely impractical for professional men with no military experience at all to record the story adequately. Clearly, it was the inescapable responsibility of the Surgeon General to assume the task.

Discussions on the subject were initiated in March, 1944, and, after an extensive series of conferences, which were gradually expanded to include all concerned in the project, the official Medical Department program for the preparation of a clinical and administrative history of World War II was formally separated from the proposed program of the National Research Council.

There can, of course, be no debate about the wisdom of this change of plan, and great credit is due to those in the Office of the Surgeon General who had the foresight to initiate it and carry it through (chiefly General Love, the late Brig. Gen. Fred W. Rankin, M. C., Army of the United States, then Chief Surgical Consultant, and Col. Michael E. DeBakey, M. C., Army of the United States, then Chief of the Surgical Branch in this Division).

Editorial Policies

The Historical Unit has had five directors. The first was General Love, who deserves full credit for the initiation of the program and whose difficulties, as already mentioned, were many. The second had to divide his time between the Historical Unit and the Army Medical Library, each more than a full-time job in itself. The third held the position only briefly; in effect, this appears to have been an interim appointment. The fourth was ill during a large part of his tenure. My own appointment was effective July 21, 1954.

Administrative Volumes.—In the spring of 1946, in another change of plan, it was decided that lay historians should be employed to write the administrative volumes of the Medical Department history, on the ground that they would write more objectively than Medical Corps officers who had participated in the events. Curiously, this reasoning was directly contrary to the reasoning by which the Office of the Surgeon General had assumed the responsibility for the clinical volumes instead of leaving them in the hands of professional authors who had had no medicomilitary experience.

There is, of course, the risk of a certain lack of objectivity in material prepared by writers who, so to speak, helped to create it, but the danger is more than compensated for by the firsthand experience of these medical officers and other military personnel and by the intimate knowledge which they possess of medicomilitary matters, particularly administrative procedures and practices. No matter what their competence in the civilian field, lay historians are likely to be uninformed on such matters. The result might have been expected: Medical administration and logistics are highly specialized fields, and they have found it extremely difficult to orient themselves on them. As a result, the administrative volumes prepared under this plan have lagged. Only a single volume has been published. Other manuscripts have been prepared but must undergo extensive revision. The administrative volumes recently begun and those still in the planning stage have therefore been made the responsibility of Medical Corps and Army Medical Service Corps officers, on the ground that nobody can possibly know as much about a given experience as the man who participated in it and who many times directed it. The lack of objectivity about which so many fears were expressed has proved surprisingly infrequent in manuscripts prepared by these officers. When it is encountered, it is easily corrected by the judicious exercise of editorial authority.

It is not for a military or a medicomilitary history to fix blame or bestow praise. On the other hand, a medical historian should be perfectly free to write the facts, if he can establish their accuracy, no matter how damning they may be. A medical officer should be free to discuss controversial matters and to express his opinion on administrative matters connected with the management of patients as well as on methods of therapy. He is quite as able—perhaps better able—to evaluate these matters in retrospect than he was to act on them during the war, when he was helping to create the data he is now analyzing. These are now fundamental policies of the Historical Unit.

Clinical Volumes.—All the clinical volumes of the medical history are completely practical. The future medical officer who reads them will find certain techniques changed, but he will also find principles largely unaltered. This is because these volumes have been prepared by clinicians who were in service while the experiences which they are relating were occurring and who many times helped to shape the evolution of clinical and clinical-administrative policies and practices.

One thing that has made for difficulties in the past is the inevitable overlapping of professional and administrative details. Lay historians, with neither military nor clinical experience, apparently find it hard to understand that there is no sharp dividing line between these areas. Hospitalization, evacuation, surgical teams, staffing of hospitals, nursing services, supply—these and a dozen other phases of military medicine are of both clinical and administrative concern. Selection of personnel and recommendation of appropriate assignments, for instance, are professional responsibilities, even though they are closely tied in with administrative considerations. Equipment is a supply problem, but its development, selection, efficient use, and evaluation are professional matters. It should not be necessary as it once was, for a neurosurgeon eminent in his profession to conduct a real battle in an endeavor to insert into the history his opinion that the provision of more hemostats on the table of equipment of an evacuation hospital would have simplified intracranial surgery. This was a matter of supply, it is true, but intelligent supply must be based upon professional advice.

Most of the clinical volumes of the history have one or more chapters dealing with general administrative considerations in the particular specialty. Every chapter in the volumes dealing with the consultant system also discusses them. Just as much of the value of an official medical and surgical history of any war lies in the record of the organization and functioning of the various parts of the Medical Department as in the purely professional chapters. The clinical material, in fact, would be valueless in time of war without an efficient administrative scheme for its application. On the other hand, the primary function of the Medical Department is to conserve the fighting strength of the Army and to care for its sick and wounded. Everything else, including the total administrative function, is subordinate to that task. This is the concept upon which all the volumes of the medical history are based, whether they are administrative or clinical.

Practical Considerations

By 1954, this whole project had dragged on so long with so little to show for it, that interest in it was almost completely lacking.[4] This was evident in a number of areas.

Practically all of the clinical authors of these volumes have worked on a voluntary basis, which has its financial advantages for the Army Medical Service but also has certain practical disadvantages. There is now rather general agreement that it would have been more sensible—and in the end would probably have been easier for the authors—if they had been held in uniform until they had fulfilled their commitments for the history. For the most part, they were released with only the promise that they would perform, and the dangers of relying upon promises alone were correctly pointed out by General Love when the responsibility for the history was transferred to the Office of the Surgeon General. Most of the authors have fulfilled their obligations competently and generously, though not always promptly. As a result, the publication of certain volumes is being unduly delayed, and, as a further result, a few essential chapters in various volumes are lacking because the authors who had promised to prepare them simply failed to do so. When these failures were realized, it was not possible to remedy the situation, partly because it was too late to ask substitutes to prepare them and partly because the original authors had had the widest experience in these special fields.

In their interesting article on retrospective and prospective on medical history, written in 1919, Wood and Garrison[5] commented on these same difficulties, adding that it was incumbent upon a medical officer to carry out historical assignments, "not merely as a matter of patriotism but as a courtesy to the Surgeon neral and as a duty to himself and his Corps." In Civil War, they dealt with these matters with a ner hand. In August, 1862, when orders were issued the Surgeon General for the collection and arrange- nt of specimens for the Military Medical Museum, part of the historical program, the final sentence of responsible officer's orders stated darkly: "Should y medical officers of the Army decline or neglect to rnish such preparations for the museum, you will port the name of such officer to this office."

In the beginning, the history of World War II was tended by the same false starts and the same mis- rected and wasted efforts which had attended earlier icial histories. In particular, there were poor con- cts between the Historical Unit and the editors and thors of various volumes; what Colonel Goddard, urth Director of the Unit, called "the resulting re- ntment" can be characterized only as an under- tement.

One of the major difficulties in the early days of is program arose from the fact that clinical manu- ripts, submitted with the approval of the authors ho had prepared them and of the technical editors the volumes, had been extensively altered by pub- ations editors who had no background at all in nical medicine and only a limited experience in oduction work. This practice has long since been opped. Manuscripts received with the approval of thors and editors are now never altered in substance cept upon the initiative of the Editor-in-Chief, and, matters of any consequence, only after consultation th the author or, where indicated, with other author- es on the subject.

This particular difficulty arose from a lack of cer- inty about correct editorial procedures and was to explained by a lack of certainty on the part of recting personnel. Until the summer of 1955, the litorial Branch of this office operated without a ief, each publications editor going her own way and porting directly to the Editor-in-Chief. This would t have been a satisfactory method of procedure even the publications editors had been persons of extreme mpetence and wide experience, which they were t. In July, 1955, after a search of almost a year and, ite literally, all over the country—Civil Service could t help—a competent and highly experienced produc- n editor was found, and these particular difficulties e now ended. Publications editors are now aware at, in clinical and other technical volumes, even ght changes of expression may produce complete anges in sense. The authors of these volumes repre- nt the best professional ability in their special fields, d the unwarranted changes made in their manu- ripts in the past, of which they rightly complained, e no longer permitted. Revision in the Historical nit is now reduced to the irreducible minimum re- ired by the rules of the Government Printing Office.

Competent personnel in any field are hard to obtain d hold. It would be desirable to employ as publica- ns editors only personnel who have had at least a limited experience in production work and who have been exposed to the language and associations of clinical medicine. No such personnel have ever been employed by the Historical Unit, and the solution of the problem, once competent supervision was obtained, was a process of in-training. This is neither easy nor satisfactory, and it is also wasteful. The best workers in this special field are those who, over a period of years, have accumulated their knowledge and skill by a process of osmosis rather than by direct indoctrination and formal training. In-training is a compromise, but one which is at last beginning to pay off.

A certain amount of verification of data is necessary, as will be pointed out shortly, even in the clinical volumes of the history. This necessity implies, or should imply, sufficient background on the part of publications editors to recognize the difference between established facts and facts of general knowledge, which do not require verification, and those data which must be verified. It should also imply the ability to distinguish between factual data and the clinical opinions and conclusions which are exclusively the affair of the author. A publications editor who does not know what not to check as well as what to check can be a real handicap in an office, as past delays in the publication of clinical volumes of this history have clearly proved.

One serious defect still exists in the set-up of the Editorial Branch of the Historical Unit—the lack of a trained medical indexer. This deficiency is particularly serious in the clinical volumes, which cannot be useful tools unless they are provided with comprehensive indexes. The preparation of an index of this kind, in which the listings not only are adequate but also are correctly related to each other, is not a task for untrained personnel. This problem, to date, has been handled by a series of expedients, none of them really desirable and all of them wasteful of time, trained personnel, or both. Meantime, the search for a publications editor with medical indexing experience still continues.

At the present time, the Editor-in-Chief of the history personally reads all manuscript in its final form (as well as, very often, in preliminary form). All production work, as just mentioned, is now supervised by a competent and experienced chief production editor. Schedules of production are established and maintained. The variation in editorial style from volume to volume which characterized the first books published in the Medical Department series has now ended. A standard format, type face, and general lay-out have been established. There is a consistent form for tables of contents, including lists of illustrations, tabular data, and the academic and other appointments of contributors. Index listings are also consistent. The last two volumes published ("General Surgery II" and "Orthopedic Surgery in the European Theater of Operations") are the first to be published under the circumstances just described. They represent the finest work of which the Government Printing Office is capable.

Statistics.—A major problem in the past has concerned statistics. The Statistical Division, Office of the Surgeon General, supplies and verifies all official statistics, such as theater-wide and Army-wide incidences of total and special types of injuries and diseases, case fatality rates, hospital stay days, and similar items. A distinction must be made, however, between these official statistics and special statistical studies made, just as in civilian life, by qualified medical officers because of their own particular interest in certain subjects or at the direction of their superior officers. The whole section on abdominal injuries, for instance, in the volume entitled "General Surgery II" is based on statistics of the 2d Auxiliary Surgical Group which were collected, as a special project, under the direction of Col. James H. Forsee, M. C., the Commanding Officer. For a number of reasons, chiefly the selective element, these statistics do not correspond with the official statistics. They are also broken down into details which would be impractical in officially collected statistics. Similar special studies appear in other volumes.

All of these statistical studies were analyzed fairly and in the light of professional knowledge and experience. The conclusions drawn from them are warranted, if not to professional statisticians, to professional medical officers of wide knowledge, training, and experience. Clinicians are in general agreement that neither diagnosis nor therapy should be deferred until a level of statistical significance has been achieved. If the profession had waited for a level of statistical significance in regional enteritis, it would not now know what it knows about the disease; the original description, which is still essentially correct, was based on the observation of 14 cases, a sample which many a professional statistician would probably view with horror. Similarly, many of the cardiac and vascular operations which are now achieving miracles would still be in the testing stage if they had not been generally employed before statistically significant proof of their value had been secured. The approach to the personally collected statistics in the medical history of World War II is along these same lines.

Documentation.—The question of adequate documentation in an official history is of great importance but is reduced to nonsense if the approach is not along lines of common sense. Greenfield states that, during World War II, the Army produced 17,120 tons of records, enough to fill 188 miles of filing cases set end to end.[4] The reviews of some of the purely military volumes mention that they "stagger under prodigious and pedantic minutiae" and "practically groan under their load of footnotes." This kind of false scholarship is just as undesirable as carelessness in documentation when documentation is required. The present endeavor is to strike a happy medium, to use precise references to official documents, to check all facts which can be checked, particularly when they are disputatious, and thereafter to accept the word of the man who was there, even though his recall is perhaps less than tot This is in line with Baldwin's opinion that too mu research makes a historical writer unable to select a summarize, that trivia may obscure lines of devel ment, and that it is well for the writer, at least to so degree, to free himself from what Baldwin well ter "the hangman's noose of scholarship."

The Use of Proper Names.—The history of the Ci War followed what General Weed, as well as Wo and Garrison, termed "the bureaucratic practice" o giving no credit to individual authors. In World War I all chapters of the medical history were, properl accredited to the men who wrote them, and the sa policy is being followed in the history of World W II. For one thing, this is only simple justice. For a other, a great many of these names carry with them clinical or military authority, or both, that would totally lacking in anonymous contributions.

Furthermore, actual names are mentioned throug out the history as is necessary. "Hamlet" could scarc ly have been written without mentioning Haml This is, of course, in violation of the old rule th one uses a name in history only when the menti would embellish the history, never when it wou embellish the name. Names are mentioned in history of the U. S. Army Medical Department World War II just as they would be mentioned any other kind of writing, if only to avoid the cumb some wording and actual confusion which can ens when one uses only titles.

Peripheral Editing.—Bernard DeVoto,[6] himsel Pulitzer prize winner in history, had some useful marks to make about what he termed "compulsiven about unimportant error." There will always be, said,

> small errors of fact, small misstatements, small misconcepti some of them will result from the author's inadvertence others from his blithe ignorance—and they do not matter in least. What does matter is that there have been no impor errors, and it is folly to waste care that might be spen preventing *them* in the illusory hope of preventing mar ones. . . . There is a professional tendency to make equally important, and in fact to penalize the peripheral e more than a cardinal and central misconception. The pro sional vision is trained to be so microscopic that it someti ceases to be binocular.

Compulsiveness about unimportant error is pro ably the chief reason for previous delays in the pub cation of the volumes of the history of the Medi Department in World War II. It is now ended. No o volume in the series will represent perfection in eve sense. All of them, no doubt, will contain minor erro of omission and commission; perfection is seldo achieved in this imperfect world. Authors, editors, a everyone else connected with these volumes ha done their best, and the result will be an honest, fact ally correct, well-rounded account of the work—th outstanding work—of the Medical Department of th Army in World War II.

rocessing of Manuscripts.—Certain other details in processing of these manuscripts for publication erve comment, for certain procedures are required an authorized history not necessary in volumes ited under civilian auspices.

'or one thing, when the final manuscript is read, it st be decided whether any agency of the govern- nt in addition to the Medical Department has suffi- nt interest in, or association with, the particular ume to require clearance of it. The Public Informa- n Office must clear all manuscripts for security. This chiefly a formality in the clinical volumes but not he administrative volumes, the preparation of which uires the use of a considerable amount of material t is still classified.

The final step in the processing of a volume of the tory is its submission to the Government Printing ice through the Office of the Adjutant General. The ter office has the authority to pass upon and to ap- ove, or withhold approval from, all matter published the Army. Illustrations are its particular concern. en when that office is sympathetic, as it has gen- lly been since the special problems of the medical tory have been brought to its attention, this step l means a minimum delay of four to six weeks. When once the manuscripts reach the Government nting Office, production processes are the same, in ence, as they are in any commercially printed book.

Advisory Editorial Boards

It is regrettable that, in the planning for the history World War II, attention was not paid to the editorial ard which existed in World War I. It was not utilized wisely as it might have been, but it was appointed omptly and it served well.

This board was appointed by the Surgeon General January, 1919. It consisted of 28 medical officers, men of wide experience in the Regular Army Med- l Corps and the Reserve Corps, and all outstanding their several specialties. The board was too large to really functional. At the first meeting, in the fall of 19, practically all of the members were present, but ere were no other full meetings, because, ironically, nen it was practical to hold meetings they were not cessary, and when they were necessary they were t practical because of demobilization of Reserve ficers and changes of assignment of Regular Medical orps Officers. Additional meetings were therefore tirely informal. On the other hand, even though the echanism of their formal use proved too compli- ated, collectively and individually the members of is board rendered signal service.

The first advisory editorial board of World War II as open to the same objections as the advisory edi- orial board of World War I. It was appointed in April, 946, and it convened promptly. Its distinguished nembership represented the Medical Corps of the rmy, medical educational personnel, and editors of nedical publications. At the first meeting the general plan of the history was approved and advisory services were arranged for. As time passed, however, it became evident that no single board could cover the whole field of the history, and eventually—far too late—advisory boards were appointed in the various special fields, as follows:

The Advisory Editorial Board on the History of Preventive Medicine, appointed in 1948, was formerly under the chairmanship of the late Brig. Gen. James S. Simmons, M. C., U. S. Army (Ret.). It is now headed by Brig. Gen. Stanhope Bayne-Jones, M. C., Army of the United States (Ret.). The work on this series is being done under a contract with the Medical College of Virginia at Richmond, under the editorial direction of Dr. Ebbe C. Hoff, professor of neurological science at that institution.

The Advisory Editorial Board on the History of Internal Medicine, appointed in 1952, is under the chairmanship of Dr. Garfield G. Duncan, clinical professor of medicine, Jefferson Medical College, Philadelphia. The work on this series is being done under a contract with this school, under the editorial direction of Dr. W. Paul Havens, associate professor of clinical microbiology.

The Advisory Editorial Board on the History of Surgery, appointed in 1953, was formerly under the chairmanship of the late Brig. Gen. Fred W. Rankin, M. C., Army of the United States (Ret.). It is now headed by Dr. Michael E. Debakey, professor of surgery and chairman of the department, Baylor University College of Medicine, in Houston, Texas. The work is being done under a contract with the Tulane University of Louisiana School of Medicine, at which Dr. DeBakey was formerly associate professor of surgery.

The Advisory Editorial Board on the History of Training, appointed in 1956, is headed by Major Gen. Paul R. Hawley, M. C., U. S. Army (Ret.), formerly Theater Chief Surgeon, European Theater of Operations. Its entire membership consists of Medical Corps officers who were intimately associated with all phases of the training program during World War II.

Boards for the volumes on radiology and neuropsychiatry will be appointed later.

The most important function of all of these advisory boards is to expedite the publication of the history. Their formal meetings have been of great value, but informal contacts have been even more useful. It is often of greater and more immediate help to be able to pick up the telephone, speak to an authority in a special field, tell him the problem, and receive the answer, positive, negative, or merely advisory, with no loss of time. Most of the members of these boards were in service during the war years, many of them for the entire period. They represent the happy combination of specialized medical knowledge and medicomilitary experience required for this work. They have given freely and generously of their time, and they have been of incalculable service to the history.

In this same connection, it is appropriate to thank the authors and editors of these volumes, who have given their time and effort without remuneration to this work. Particular gratitude is due to those who bore the brunt of the inadvertent false starts, misdirected efforts, and other errors which were made in the first years of this project and because of which some of them have had to attack their material a number of times. Many of them have had every reason to be resentful, but they have forgotten their own rights in the interest of doing this job and doing it well.

The Surgeon General of the U. S. Army has played the chief role in all recorded histories of the Army Medical Department. It was the Surgeon General of the Civil War, General Hammond, who had the percipience to start preparations for the history of that conflict only a year after it began. It was the Surgeon General of World War I, General Gorgas, who set up preparations for the history of that war only a few months after the United States had entered it. It was General Magee, then the Surgeon General, who in 1941 established the Historical Division in his office while the United States was still outside of the conflict in World War II. His successors have continued his work. In my own term of office, I have had the warm support and encouragement of Gen. S. B. Hays, the present Surgeon General, his predecessor, Gen. George E. Armstrong, their deputies, and other key members of their staffs, as well as the personnel of various agencies of this Office. It is not an idle phrase to say that the history of the U. S. Army Medical Department in World War II is prepared and published under the direction of the Surgeon General.

Costs

The volumes of the World War I medical history were prepared and published between 1919 and 1929. It is completely unrealistic to relate the cost of those volumes to those which comprise the history of World War II but the comparison has its interesting aspects.

The history of World War II, as would be expected, is a far more ambitious undertaking than the history of World War I. The cost of living has advanced enormously since 1929, and production costs have climbed along with it. Personal remuneration has also increased enormously, although, as already pointed out, most of the clinical manuscripts have been prepared by authors who received no remuneration for their services and who have not always received recompense for their expenditures for secretarial help and other items. Also to be taken into consideration are the false starts and misdirected efforts which General Weed so frankly reported in his *apologia pro historia sua* and which, regrettably, have also occurred in the present project.

The original appropriation for the medical history of World War I, for $50,000 in the fiscal year 1921, was accompanied by the entirely unrealistic restriction that the total cost must not exceed $150,000. Congress promptly removed this restriction, and the total cost, including salaries of personnel, was eventually $576,991.71.[1] After the first few volumes had been published, it was thought that publication costs could be kept to an average of $10,000 per volume, b the end of the task, the average for all volumes almost $13,000. If two volumes are excluded w presented special typographic difficulties, the ave cost per volume was about $11,450, about 14 excess of the working figure of $10,000. As the pr neared its conclusion, some volumes had to be r smaller than had been planned in order to keep wi the financial limits set. Costs increased, even in t days, in an incredibly short time.

Total figures for the World War II history are yet, of course, available, but it is interesting to obs that the unit cost of production has varied from $12 for the first clinical volume, which was printed on coated stock, to $4.18 and $3.84 (estimated), resp tively, for the last two volumes, which were produ under competent editorial supervision and printed fine coated stock. It is doubtful that these costs be reduced in future volumes. The clinical volu particularly, are expensive. They must be printed o high grade of paper if the detail of illustrations is be properly brought out. The economy in that resp practiced in the earlier volumes was an error wh will not occur again. This mistake, together with err in reduction, seriously mars the appearance of t volume on hand surgery.

The history of the U. S. Army Medical Departm in World War II has cost a great deal of mone date, and it is going to cost a great deal more b it is completed. We owe it to the taxpayers of t country, among whom we are all represented, to k the costs down as far as is consistent with the cont and format required to produce quality work. W one considers the huge sums eventually involved in preparation and publication of a massive histor is incumbent upon all concerned to put forth th best efforts to make it the best work possible.

Current Status of the History

The volumes that make up the series entitled "Me cal Department, United States Army in World W II," are part of a total series of about 125 volu dealing with all aspects of the war in all theater which it was fought. These volumes, in contrast Samuel Eliot Morison's history of the Navy, which frequently described as "unofficially official," constit the official history of the Army. Eighty military v umes are to be published by the Office of the Chief Military History, U. S. Army, under the general edit ship, as already noted, of Kent Roberts Greenfield

The number of volumes in the Medical Departme series, like the number planned in the military ser has varied from time to time. The present plann envisages about 45. We have avoided, in all but o of our groups (preventive medicine), an error th plagued the producers of the history of World War We have not numbered our volumes, a practice whi is feasible only if all the material is on hand befo publication of anything is undertaken. Histories a not thus written.

Seneral Weed said, rather bitterly, that in the World ır I series, because volume XV was published first, production of 14 other volumes was required. As tters worked out, it proved necessary to publish even larger number, because some material spilled ɜr its limits and these volumes had to be published two parts each. Then, at the last minute, the au- ɪrs of a planned volume on radiology defaulted, and ʼolume on pathology, which had been deleted, had be hurriedly prepared to take its place because ɜre had to be a volume XIV. The planning for, and ɜrefore the number of, volumes in the World War II tory have varied from time to time, and it is well leed that the World War I plan was not followed, ɜ difficulties being sufficiently numerous without ding this one.

By calendar year. No volumes were published between 1946 and 1951 and ıe were published in 1953 and 1954.

Every conceivable effort is now being made in the ;storical Unit, consistent with personnel and funds ailable, to eliminate bottlenecks and concentrate ɪon completing the long-overdue history of the med- ıl effort in World War II. In July, 1954, there was ailable a large amount of material that was com- ɜted or that could easily be completed. Some of it ıs physically in the Historical Unit. Some of it was ıll in the hands of authors and editors, who, under- ındably, were making no effort to move it because thing had happened to material already submitted, me of it four to seven years earlier.

:The simple military tactic was employed of breaking ·rough at the weakest point; that is, all the effort was ncentrated upon the volumes nearest completion, ther than dispersing the rather limited resources of e Historical Unit over a great many volumes. This ɔlicy has paid off, not only in volumes published :able 1) and in press and being prepared for publica- on (table 2) but in the changed attitude of all con- ɜrned in this work.

Volumes of the medical history of World War II ıblished to date include the following: In the pre- ɜntive medicine series, "Personal Health Measures and nmunization" and "Environmental Hygiene," both in ɔ55. In the administrative (technical) series, "Hos- italization and Evacuation, Zone of Interior," in 1956. In the surgical series, "The Physiologic Effects of Vounds," in 1952; "Vascular Surgery," in 1955; "Hand urgery," in 1955; "General Surgery, Volume II" (vol- me I will appear later), in 1956; and "Orthopedic urgery in the European Theater of Operations," also ı 1956.

In the miscellaneous series, "Dental Service in World War II," in 1955.

Two volumes are now in press, "Orthopedic Surgery in the Mediterranean Theater of Operations" and "Ophthalmology and Otolaryngology," both in the surgical series. In preparation for press are two volumes in the preventive medicine series, two volumes in the internal medicine series, one of the two neurosurgical volumes in the surgical series, and "Cold Injury, Ground Type," in the miscellaneous series.

Utilization of the World War II History

Colonel Goddard had the excellent idea of trying to find out what useful purpose the medical history of World War II might serve by investigating what purpose the history of World War I had served.[3] Medical officers performing administrative functions doubted that the clinical volumes would offer much of value, partly because of the delay in getting them into print and partly because all significant items of medical progress achieved during the war were already available in the periodical literature. In 1951, 161 questionnaires were sent out to the libraries of foundations, government agencies, colleges and universities, municipalities, professional schools, and professional societies, both in the United States and overseas, which had been given complete sets of the history of World War I. The (few) medical libraries which had received these sets were also questioned. The great majority of the 110 questionnaires which were returned indicated that through the years almost all the calls had been for the clinical volumes and that the interest in the World War II history would be chiefly in these same volumes. The rather naïve astonishment of those who prepared and analyzed these questionnaires indicated that the nature of the replies was quite unexpected.

TABLE 2.—*Medical Department, United States Army in World War II: Current Status of Volumes*

No action	2	...	2	...	2	1	7

This same question arose at the April, 1956, meeting of the Advisory Editorial Board for Surgery, in connection with the neurosurgical volumes.[7] These volumes, sent to the Historical Division in June, 1947, had never been published, and the authors of the various chapters, despairing of any official action, had published their own material. The editors of the volumes, who had every reason to be pessimistic in the light of their past experiences, therefore proposed to limit the resurrected material to a brief account of certain administrative problems and an equally brief account of the evolution of methods and techniques. The idea was not well received by the board. The sense of the meeting was that, as a matter of convenience and practical usefulness, quite aside from its historical value, the original material should be published as part of the official history. The editors have acquiesced with good grace, and the neurosurgical material is being reconstituted on the original basis.

The title of the World War I history, "The Medical Department of the U. S. Army in the World War," was adopted after much deliberation. The title first suggested, "The Medical and Surgical History of the World War," was discarded for a number of reasons, but the changed title, wrote General Weed, was a mistake, for it "smacks of meticulosity and . . . the reasoning which led to its adoption was faulty."

Particularly interesting is his statement that the desire to reach the widest possible range of readers would have been facilitated by the term history in the title and was frustrated by dropping it. He mentioned that the most widely circulated medical journal in the United States (presumably The Journal of the American Medical Association) described volume I of the World War I history in a book notice as the "Report of the Surgeon General." As a result, he continued, many potential readers, such as Medical Reserve officers no longer in service, remained permanently in ignorance of the existence of the history of the Medical Department in World War I.

We paid for this ignorance in World War II, as DeBakey[8] pointed out in his Ether Day address at Massachusetts General Hospital in 1946 and as many of the authors of the World War II history as well as others have attested. The ignorance was entirely real. One author read with avid interest the introductory section which had been provided for the chapter he had prepared for the history of World War II and which dealt with the story of his specialty in World War I. He inquired where on earth it had come from. It had come directly from the official history of the first World War. In shining contrast is the story of how Col. (later Major Gen.) Guy B. Denit, M. C., went ashore in North Africa carrying as an essential part of his impedimenta certain volumes of the history of the Medical Department in World War I.

The volumes of the history of the Civil War were published in the "family Bible" size. The volumes of the history of World War I were published in the smaller royal octavo size, but they did not escape what General Weed well termed "ponderosity." Four of them, he noted, weighed an average of 8 lb. each. These are reference works, it is true, but, as he said, this is far too heavy for the "dictates of convenience." Volumes of this size, from 650 to 1,000 pages each, printed on coated stock, tax the lasting qualities of their binding, and their size actually interferes with their use. Certainly they do not lend themselves to being carried ashore on D-Day.

The volumes of the history of World War II more readily handled (the average weight of the recently published volumes is something under 4 each), even though they do not meet the desire— laudable but not very practical desire—of one of t editors, who visualized something small enough carry in his coat pocket. These volumes are, howe small enough to be readily usable, several at a t if necessary.

Distribution.—If we are to avoid the limited usef ness of the volumes of the history of World War we must make the volumes of World War II m generally available. This means that their existen must be publicized. There must be careful distribut of the copies which are given to organizations and stitutions, as well as legitimate publicity for the cop which are for sale by the Superintendent of Do ments, U. S. Government Printing Office, Washingt D. C., at the remarkably low price, incidentally, about $4 each.

The distribution of the Civil War history was e tirely individual. In 1869, Congress authorized t printing of 5,000 copies, 1,000 to go to the Sena 3,000 to the House, and 1,000 to the Surgeon Gener for distribution. The demand was great, and a seco printing in the same number was authorized and si larly distributed in 1875. As a result of this system, t sets, for the most part, went into private librar They were available to relatively few readers, partic larly to those who might have benefited most by the and the expressed objective of all the toil and troub that had gone into their preparation was not realiz At the present time, when the demand for them increasing, these volumes, as well as the volumes the World War I history, are becoming scarcer more difficult to obtain.

When the first volumes of the World War I hist were published, the number printed, 3,000, was c sidered ample to supply all stations of the Army, important public libraries in the United States, all similar libraries in leading foreign nations. Th first volumes were electroplated, but this practice later discontinued, in the name of economy, thou as a matter of fact the saving thus effected was im diately cancelled out by a rise in the cost of printi

The distribution list of the World War II histor represents a serious endeavor to meet Hanson Baldwin's comment on the military volumes, that p sons must be found to read these books as well funds to pay for their production. The medical v umes are being sent, without charge, to the librar of all medical schools in the United States and Cana the most important medical journals in this coun and abroad; all Army installations; other governme agencies; selected heads of medical services in cou tries with which we are allied; and certain membe of Congress, upon request.

The copies which go to medical schools are acco panied by a covering letter from the Surgeon Gener in which it is pointed out that these books are of re ortance to the young men who must, almost in- tably, be prepared to serve in the Medical Corps of ne one of the armed services when they finish their dical course. It is also suggested in this letter that se volumes could play a useful part in the Medical ucation for National Defense (MEND) program w operative in some 25 medical schools, which has its purpose the teaching of the principles of military d disaster medicine.

n his covering letter to the editors of medical jour- s, the Surgeon General has pointed out that the rent value of these volumes is quite as great as ir historical interest. They contain the essential dical facts which must be our bulwark against fu- e disaster. In the next war, if it should come, there ll not be months of time available to mobilize and in troops. There will be no time for medical officers wly inducted into the Army Medical Corps to go to fessional schools to learn surgical techniques or to to staff schools to learn medicomilitary procedures. e medical profession itself will not be sufficient to e for casualties. Dentists, veterinarians, nurses, even technicians, will all be obliged to extend their ac- ities beyond their immediate fields of training. ese books can show them the way.

In 1948, in a perceptive review of a volume of the litary series of World War II histories dealing with Army Ground Forces, Hanson W. Baldwin wrote:[9]

> e approach is in the best tradition of the historian: "Get the th; let the chips fall where they may." . . . The inescapable pression of these . . . volumes is one of almost indescribable nfusion in our attempts to raise an army, of constant changes plan, of a babel of many voices . . . of the lack of a clear, dered staff procedure and policy. Yet—and this is the diffi- lty of the organizational plan of the Army's history—I have und it difficult to trace down the reasons for this situation to eir sources . . . I have, therefore, a suggestion to make to the storical division and the Army General Staff. Someone—obably not a historian . . . should go through these volumes . and extract from each for training purposes the major mis- kes made and lessons learned in World War II in training, ganization, administration, planning, and leadership. There is nsiderable danger—and some evidence—that our present ex- nding Army is making some of the World War II mistakes l over again. The history project (aside from its other great lues) will have more than paid its way if the lessons of the st can be utilized in the present. They are all here . . . but ey will never be learned from these volumes as they stand. meone must cull them, sharpen them, arrange them, simplify em—and, particularly, shorten them. So doing, we might save me and effort—and lives.

I was not familiar with Baldwin's proposal when, bout a year ago, I began to urge that precisely this ind of action should be taken with the volumes of le medical history when the whole project is com- leted. It is the business of the Historical Unit and its ersonnel to provide the facts of Medical Department ctivities in World War II. Their evaluation and inter- retation are the business of a later day. The review nd analysis proposed should be made by as represen- ative and as high-powered a board as can be assem- led. Every branch of the Army Medical Service hould be represented on it. This is not a task for historians. It is a task for experts in all fields of military medicine. In short, I hope that the volumes of the history of the Medical Department in World War II will eventually be subjected to exactly the same analytical process as Baldwin has advocated for the strictly military volumes. "So doing," as he says, "we might save time and effort—and lives."

In 1946, in an (unpublished) address before the Society of Medical Consultants to the Armed Forces, Dr. R. Glen Spurling, editor, with Dr. Barnes Woodhall, of the neurosurgical volumes of the history, wrote as follows:

> We are now engaged in the preparation of the history of the Medical Department in World War II. I very much hope that we shall make it a frank record of our mistakes as well as of our achievements, of the difficulties under which we labored and of possible solutions for them. . . . How frankly and fully [these volumes] are written will determine how many mistakes we can avoid if we are ever again put to the test.
>
> I passionately hope that the need for mobilizing civilian components of the Army Medical Corps will never again come in our lifetime, or in the lifetime of our children. But if the unhappy duty of mobilizing for a third World War should fall upon our own or upon some succeeding generation, that task will be easier if the record of the past is written so plainly that it cannot be misunderstood.

As Editor-in-Chief of the history of the U. S. Army Medical Department in World War II, this is exactly what I am trying to accomplish.

Addendum

Since this report was prepared, "Orthopedic Surgery in the Mediterranean Theater of Operations" has been published in the surgical series.

The opinions expressed are my own and do not necessarily express those of the Surgeon General, U. S. Army.

DIAPER RASH

FOR centuries skin eruptions in the diaper region have plagued infants and those responsible for their care. Kaessler[1] states that few infants escape this condition entirely, and Benson and co-workers[2] believe that in recent years the incidence of persistent diaper rash has increased. The term is somewhat of a misnomer, because in most cases the diaper itself is not the cause of the rash; but it is a convenient term for a group of unrelated conditions and is not likely to be abandoned. The commonest cause is the breaking down of urea with the resulting formation of ammonia. Bacterium ammoniagenes is the organism most commonly responsible for this. Other rashes in this region that may occur independently concomitantly are miliaria rubra or prickly heat, thrush, excoriation associated with diarrhea, intertrigo, seborrheic dermatitis, and allergy.[3] A severe rash may be complicated by secondary infection and ulceration. Diaper rash in general is aggravated by lack of cleanliness and maceration of the skin.

The treatment varies with the cause to be removed. As an aid to healing, the diaper area should be kept warm and dry. In severe cases this may necessitate placing the baby under an electric cradle, allowing him to lie on one or more spread-out diapers. Swift[4] advocates the use of hydrocortisone ointment followed by zinc oxide ointment or zinc oxide (Lassar's) paste. Kahan and co-workers[3] state that the ideal preparation for local application should be moisture-repellent, keratolytic, and bactericidal. They used an emulsion containing 3% silicone, which is moisture repellent; 0.2% allantoin (glyoxyldiureid), which is keratolytic; and 0.25% hexachlorophene, which is bactericidal. All three principal ingredients have the advantage of being nonirritating and nonsensitizing. The mothers were instructed to (1) make no change in the general care of the infant, (2) avoid the use of oils, lotions, ointments, or powder on the skin but apply the emulsion two or three times a day instead, (3) clean the diaper area with lukewarm water after urination or defecation, and (4) report any aggravation or untoward reaction. With this regimen they obtained excellent results. Kaessler[1] used a similar preparation in powdered form and obtained a clearing of the rash in 6 to 28 days. The results in a control series using ordinary baby talcum powder were not as good. Swift found treatment with silicone preparation effective but no better than that with zinc oxide ointment or zinc oxide paste. The silicones have the disadvantage of being more expensive.

It has been said that the practice of pediatrics should be predominantly preventive, and indeed much can be done to prevent diaper rash. Changing diapers as soon as possible after they become wet or soiled prevents maceration of the skin and the formation of ammonia. Because plastic or rubber pants have the opposite effect, their use should be limited to brief social occasions when prompt changing would be inconvenient. Rubber pants should never be left on throughout the night. Much attention has been given to the proper laundering of diapers. Benson and co-workers compared the results of home laundering with those of commercial laundering. The technique used in the home on the average consisted of soaking in cold water, washing in hot suds, and triple rinsing in water. The technique used in commercial laundering was much more elaborate, consisting of three initial rinses (warm and hot), two soapings at 180 F, bleaching, three rinses in hot water followed by a rinse in methylbenzethonium and another in zinc silicofluoride, the total process taking over one hour. Bacteriological and chemical testing showed that commercial laundering was much more effective in removing and inhibiting growth of ammonia-forming bacteria and in removing irritant detergents. Brown and Wilson[5] studied the effectiveness of various preparations used in diaper rinses and found that 3% phenylmercuric acetate was the best antiseptic: mehylbenzethonium and RH 3104, both quaternary ammonia compounds, effectively inactivated urease so that the decomposition of urea to ammonia was inhibited, and zinc silicofluoride enhanced the inactivation of urease by the quaternary compounds. They concluded that the best results required treatment of diapers with a combination of bactericide, a urease inhibitor, and zinc silicofluoride.

Although commercial laundering is not essential to the prevention of diaper rash, the nearer a home laundering procedure can approximate that of commercial laundries the better the protection. It is doubtful that many homes would find the elaborate technique used in commercial laundries practicable. Finally, it should be emphasized that preventive measures must be continued as long as diapers are worn.

THE JOHN J. ABEL CENTENNIAL

The American Society of Pharmacology and Experimental Therapeutics commemorated the centennial of the distinguished scientist John Jacob Abel on September 5, 1957, in special ceremonies at the Johns Hopkins medical institutions in Baltimore. His career tells a story of how scientific medicine develops and in principle is not unlike the history of other outstanding figures in medicine. Such men are a source of inspiration for those who may wonder if the long road in medicine and research is worth following.

Dr. Abel, who was born near Cleveland on May 19, 1857, received his Ph.B. degree from the University of Michigan in 1883, his college education being interrupted for a three-year period when he was principal of the high school and later superintendent of the public schools at La Porte, Ind. After graduation, he spent a year in the department of biology at Johns Hopkins University, after which he went abroad for seven years studying medicine and doing postgraduate work under such celebrated teachers as Ludwig, Von Frey, His, Strümpell, Kussmaul, Von Recklinghausen, Naunyn, Hoppe-Seyler, Von Nencki, and Schmiedeberg. It was Schmiedeberg, long regarded as the father of modern pharmacology, who stimulated Abel's interest in pharmacological research, particularly in its chemical aspects, and it was on Schmiedeberg's recommendation that Dr. Abel was offered the first full-time professorship of pharmacology in the United States, founded in 1890, at the University of Michigan. In 1893, Dr. Abel left Michigan to assume the chair in pharmacology at the newly organized medical school of the Johns Hopkins University, a position he retained until his retirement in 1932. From then, until his death in 1938, he served as the director of endocrinological research at the university.

Prior to Dr. Abel's appointment at the University of Michigan, materia medica and therapeutics were taught by physicians engaged in private practice. Dr. Abel, however, introduced Schmiedeberg's methods of instruction, which included lectures, demonstrations, and quizzes and instituted the use of student experiments. His prodigious energy and unbounded enthusiasm exerted a strong influence on both his students and assistants, many of whom advanced to important positions in medicine or the medical sciences.

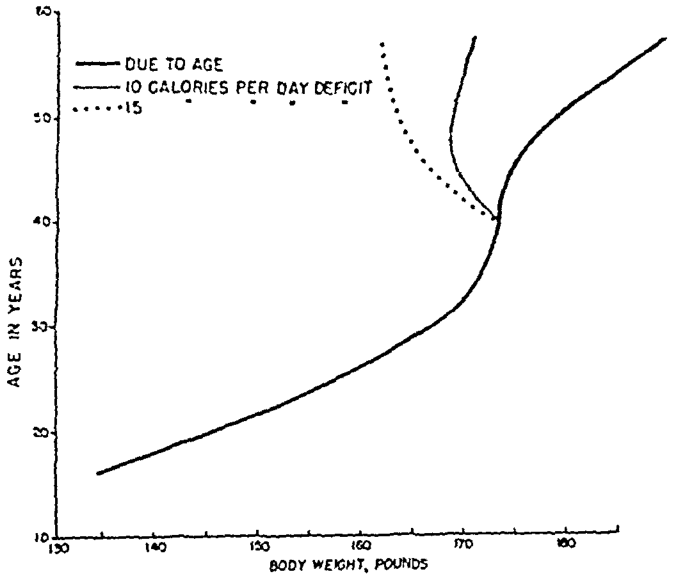
Dr. Abel's research activities covered a wide range of subjects, from his earliest researches on the "molecular weight of cholic acid, cholesterol and hydrobilirubin" to the studies on the mode of action of tetanus antitoxin, undertaken after his retirement from active teaching. Possibly his best-known works were the isolation of the benzyl derivative of epinephrine, the active principle of the adrenal medulla, in 1897, and the preparation of crystalline insulin in 1926. These studies, and his extensive work on the purification of the active principles of the posterior lobe of the pituitary gland, were facilitated by the broad training he had received in Europe, where he first came to appreciate the great role that chemistry would play in the future development of scientific medicine. His prophetic instinct was also illustrated by his development, in 1913, of an "artificial kidney," capable of removing dialyzable substances from the blood of living animals by circulating it through a series of celloidin tubes surrounded by saline solution and by his introduction during the year 1921-1922 of a course in biophysics in the medical school.

Dr. Abel's contributions to the medical sciences include also the founding of several scientific journals and societies. In 1895, he suggested to President Gilman of the Johns Hopkins University the need for an American journal, covering the field of experimental medicine, and the following year, with Gilman's encouragement, the medical faculty founded the *Journal of Experimental Medicine*. The success of this journal prompted Abel to initiate the steps that led to the launching of the *Journal of Biological Chemistry* in 1905 and the *Journal of Pharmacology and Experimental Therapeutics* in 1909. On December 26, 1906, Dr. Abel called a meeting of biological chemists in New York, which led to the founding of the American Society of Biological Chemists, and, in 1909, the American Society of Pharmacology and Experimental Therapeutics was organized with Abel as its first president.

Dr. Abel's contributions to the development of basic medical science in America were truly outstanding, and his influence on contemporary workers was lasting and profound. Practicing physicians may well join with their academic colleagues in paying homage to this great scientist and teacher.

further that, since the advantages of overweight in the adolescent and early adult years has been replaced by prevention of infectious diseases and improved therapeusis, at no time in one's life span should obesity be tolerated.

In the United States the National Research Council's Food and Nutrition Board has had a tremendous impact on the thinking of the teachers in the field of nutrition. Their table of recommended food allowances is used as a yardstick for the measurement of the adequacy of the diet. There is no question that it has served a useful function and has brought about an upgrading in the general nutritional status of the people of this country. One can question whether their caloric allowances for the 65-year-old group and older are not too generous and conducive to the production of obesity. Lyons and Trulson[2] report a survey of 100 men and women over 65 years of age living in Boston. They found that 35% of the men and 52% of the women consumed 100% of the National Research Council caloric allowances –2,600 and 1,800 calories respectively; 48% of the men and 57% of the women were 10% or more above their desirable weight. This would indicate that for this group the National Research Council's caloric allowances are too high.



Increase in body weight on constant intake, 2,800 calories per day, and constant expenditure, correcting for decreased metabolism due to age. (U. S. Army photograph.)

The diet has been implicated in the genesis of atherosclerosis. This discussion will not go into the details of the arguments pro and con. No doubt, in time, atherosclerosis will be proved to have a relationship to metabolic factors. Whether these are due to faulty dietary habits and can be reversed by changes in the diet is still a very open question. There is at present no evidence which calls forth a recommendation for drastic changes in the present dietary regimen to combat atherosclerosis. A diet which will bring about and maintain optimum nutrition can be achieved by the consumption of the normal variety of foods in amounts sufficient to maintain the desirable weight.

Chronic disease states have their influence on nutritional requirements, and meals must be planned accordingly to supply the required amount of nutrients. The physician who prescribes diet therapy as part of the treatment in the aging population must make certain that the therapeutic diet not only is nutritionally adequate on paper but is actually consumed by the patient. Low-sodium diets, frequently prescribed for the aged, are particularly anorexigenic, and, if careful attention is not paid to the adequacy of the consumption, secondary malnutrition occurs, particularly with respect t protein and some of members of the vitamin complex. Paralysis agitans (Parkinson's disease may make it very difficult for the patient to fee himself. Concentrated foods in liquid mixtures ma be necessary as supplements between meals. Gastr intestinal disturbances, both functional and organi frequently lead to limitation of food choice. Th therapeutic diets prescribed for gout and diabet mellitus are more easily interpreted into good fo intakes than some of the others.

Limitation of physical activity because of my cardial disease and circulatory insufficiency a arthritis and other joint difficulties should call a compensating decrease in caloric intake, otherw weight gain is inevitable. Added body pounda causes a further load on the circulation and weig bearing joints. The precipitation of anginal pain a full meal discourages many from eating a meal. Personality changes and the negativism quently associated with cerebral arterioscler have a direct bearing on appetite and food consu tion. Socioeconomic factors must be investiga These latter, too, can determine to a large ex the food intake.

Look carefully for dental or local oral lesion a cause of poor eating. Ill-fitting dentures and gums are a real deterrent. Many functional gas intestinal upsets result from foods that have been masticated. Pay attention to the mechan state of the food as well as its nutritional cont

Basically, the nutritional requirements for aged are essentially the same as for the you adults. With the exception of recognition of decreasing calorie requirements, one need not the light of present knowledge, alter the dietary pattern. One must recognize that the metabolic status of the aged is the end-result of previous experiences and that optimum nutrition must be maintained throughout life.

MEDICINE AND THE LAW

COMPLAINT AGAINST A PHYSICIAN SUBMITTED TO A MEDICAL SOCIETY—BASIS FOR LIBEL ACTION BY THE PHYSICIAN

A patient submitted a complaint in a letter to the ew York County Medical Society which in part ad as follows: "It was guaranteed to me by the ysician, who is the subject of this correspondence, at the scar which is on my left shoulder would isappear, except for a thin and barely visible line ter the performance of the operation. Further, at this healing process would take only about ur months. Since the date of the operation, no ange whatsoever has taken place, nor has the ngth or ugliness of the scar in any way diminhed.

"The consultation which took place on Saturday etween Dr........................ and myself, was both diseartening and, I believe, unethical. Dr.................... eadily admitted to the operation's failure, indicatg that the scar would not disappear and that he id not perform a proper operation. When asked y me what he proposed doing to rectify this situaion, he suggested another operation at additional ost." The letter ended with a request for "assistnce and guidance."

One of the Principles of Medical Ethics of the ledical Society of the State of New York, of which he physician was a member, states, in part, that the promise of medical care or boasting of cares r extraordinary skill and success is unethical."

The physician and his witnesses readily admitted hat no scar can be completely eliminated and, if ncised, must of necessity be substituted by another car. The Grievance Committee of the Medical Society rejected the patient's complaint on the basis of the physician's assurance that no guarantee or promise of a satisfactory outcome had been made by him and that the procedure which he used in the operation was standard practice.

The physician then sued the patient for libel for having submitted this letter of complaint to the medical society. The court concluded "that a guarantee of removal and reduction of the scar to that of a thin and barely visible line would be reprehensible, deceitful and unethical. To falsely accuse a surgeon of making such a definitive guarantee of recovery is to impugn his integrity and professional standing as a surgeon, amounting to libel per se."

The court said that the letter, even though submitted in confidence, could be the basis for a libel action, "for it is enough that it be public and made known to persons other than the parties, even though they be members of an official body or a select and private group of professionals." The court also stated that it would be contrary to public policy to hold that the physician "being a member of the Society and thus bound by its principles and rulings must be presumed to have waived his legal rights."

Nevertheless the court dismissed this libel action as it found that the patient's assertions in her letter of complaint to the medical society were true and were made without malice.—*Kantrowitz v. Candelario, 163 N.Y.S. 2d 297, Supreme Court, Trial Term., Kings County, Part IV., May 17, 1957.*

CONFIDENTIAL COMMUNICATIONS AND RECORDS

This is the third in a series of six articles dealing with the necessity for and proper format of certain medicolegal forms. The subjects to be covered are (1) consent to operations and other medical procedures; (2) patient's right to privacy; (3) confidential communications and records; (4) artificial insemination; (5) the physician-patient relationship; and (6) autopsy.

This material has been prepared and will be published in book form by the Law Department of the American Medical Association under the title "Medicolegal Forms with Legal Analysis." The book will include extensive legal citations and a substantial number of additional forms which have not been included in this series of articles.—Ed.

The relation between a physician and his patient is an extremely confidential one. The patient should feel free to make a full disclosure of facts to his physician, in order that the physician may most effectively render his services, and the patient should be free to make this disclosure with the knowledge that the physician will respect the confidential nature of the communications. It is a breach of professional ethics for the physician to reveal the confidential communications of his patients without the express consent of the patient unless required by law, as in the case of communicable diseases. The betrayal of a patient's confidence may also be grounds for revocation of the physician's license. The physician should, therefore, obtain the express written consent of the patient before releasing confidential information.

Confidential communications between physician and patient have *the statutory status of privileged* communications in some states. In states where communications have this status, the physician may not testify *in a judicial or administrative proceeding* as to information obtained as a result of the physician-patient relationship.

The privilege also extends to hospital records insofar as they tend to disclose what the physician learned in the course of treatment. Generally, it has been held that, where a physician is employed by an insurance company or other adverse party to examine a claimant, with no contemplation of any treatment, the information thus acquired is not privileged and the physician may testify as to such information.

In order for privilege to apply, it is *not necessary* that any treatment shall actually have been given; all that is necessary is that the information shall have been gained for the purpose of aiding in treatment.

The communication is privileged if it is made in the presence of a third person who is aiding the physician or who is necessary as a means of communication between physician and patient. But, if the communication is made in the presence of a third person, who is not assisting the physician and *who is not necessary* as a means of communication between physician and patient, it is not privileged. It has been held in some states that, in such a situation, only the third person, but not the doctor, could testify as to the communications, while in other states it has been held that both the doctor and the third person can testify as to the communications. If the communication is made in the presence of a third person whose character is such that the communication is nonprivileged, the patient cannot be compelled to testify as to the communication.

The privilege belongs not to the physician but to the patient, who may waive it. The patient's bringing of a professional liability action against the physician may constitute a waiver of the privilege. The privilege may may also be waived if the patient testifies as to the communications or if he calls the physician as a witness.

Fundamentally, the physician-patient privilege, which exists in many jurisdictions in various forms, is a limited right of exclusion of evidence in a judicial or administrative proceeding. Ordinarily, it does not present any issue of legal right of recovery for violation of the privilege. In seeking to recover against a physician for the alleged improper disclosure of information, it appears that the patient's basis for recovery, if any, would depend upon his ability to establish a breach of his right of privacy. This is an area of law which is still in the process of development.

FORM 1.—*Authorization for Disclosure of Information to Examining Physician*

I authorize Dr. .... to

disclose complete information to..
concerning the results of a physical examination of the

undersigned made or to be *made on*..

19........, and to testify, without limitation, as to all findings *of said* physical examination, in any legal action or judicial *proceedings* to which I am, or *may* become a party; and I *waive on behalf of myself and any persons who may have an interest in the matter, all provisions of law relating to the* disclosure of information acquired through *said* examination.

Signed ....

Place ....

Date ....

MEDICAL NEWS

ARIZONA

General Practitioners Meeting in Mesa.—The annual meeting of the Arizona Chapter, American Academy of General Practice, will be held Oct. 12-13 at the Maricopa Inn, Mesa. The program includes the following guest specialists: Dr. Karl O. Van Hagen, clinical professor of neurology, University of Southern California, Los Angeles; Dr. William A. Brewer, surgeon, Phoenix; Dr. Herman W. Lipow, pediatrician, Phoenix; Dr. Samuel G. Blount Jr., director, cardiovascular laboratory, University of Colorado, Denver; Dr. Jack E. Brooks, eye, ear, nose, and throat, Phoenix; Dr. Robert W. Weber, orthopedic surgeon, Tucson; and Dr. William Dock, internal medicine, Palo Alto Clinic, Calif. A $5 fee will be charged for nonmembers. The meeting is approved for postgraduate credit, category I, for members of the academy, and is open to all members of the medical profession. Entertainment includes a banquet Oct. 12 and a golf tournament Oct. 13. A ladies' program is planned. For information write Dr. V. E. Frazier, General Chairman, Arizona Academy of General Practice, 40 South Country Club Drive, Mesa, Ariz.

ARKANSAS

Society News.—The Arkansas Dermatological Society has elected the following officers: Dr. Ray Fulmer, Little Rock, president; Dr. Ellis P. Cope, Little Rock, vice-president; Dr. Calvin Dillaha, Little Rock, secretary; and Dr. Davis W. Goldstein, Fort Smith, program chairman. Plans have been made to form a regional group of dermatologists within a radius of about 400 miles from Little Rock which will hold yearly informal meetings.

CALIFORNIA

Fourth Annual Surgical Symposiums.—The San Francisco Academy of General Practice has announced that the fourth annual surgical symposiums will be held at Fort Miley Veterans Administration Hospital, 42nd Avenue and Clement Street, San Francisco, Tuesdays at 8:00 p. m., Sept. 24, Oct. 1, 8, 15, 22, and 29. The symposiums are under joint sponsorship with the University of California School of Medicine. Practical concepts of surgical technique will be stressed and new advances in surgery discussed. The symposiums are designed to fit the needs of the general practitioner. Dr. Louis Brizzonlara, chief, department of surgery, Fort Miley, will act as moderator, and Dr. Forrest M. Willett, chief, department of medicine, Fort Miley, will be coordinator. For information write Dr. Alex F. Fraser, 3490 20th St., San Francisco 10, Calif.

Society News.—The 1957-1958 officers of the Los Angeles Radiological Society are as follows: president, Dr. Richard A. Kredel, Pasadena; vice-president, Dr. Lewis J. Peha, Beverly Hills; secretary, Dr. Putnam C. Kennedy, Glendale; treasurer, Dr. Robert B. Rickenberg, Los Angeles. The society meets the second Wednesday of September, November, March, April, and June, at the Los Angeles County Medical Association Building. The midwinter radiological conference will be held Feb. 22-23, 1958, at the Biltmore Hotel, Los Angeles.

CONNECTICUT

Personal.—Dr. Franklin S. DuBois, of New Canaan, recently named to the newly created State Board of Mental Health, was elected secretary of the group at an organization meeting in Hartford.

Hospital Anniversary Program.—A scientific meeting will be held in The Hospital of Saint Raphael, New Haven, Oct. 25 as part of a three-day celebration of the 50th anniversary of the hospital. Participants include Dr. Paul di Sant'Agnese, assistant professor of pediatrics, College of Physicians and Surgeons, Columbia University, who will discuss "Cystic Fibrosis of the Pancreas"; Dr. Charles A. Hufnagel, professor of research surgery, Georgetown University School of Medicine, Washington, D. C., speaking on "Selection of Patients and Evaluation of Procedures for Cardiac Surgery"; and Dr. Shields Warren, professor of pathology, Harvard University School of Medicine, Boston, whose subject will be "Radiation and the Human Race." A clinical pathology conference will be part of the afternoon session and will include Drs. Harold Jeghers, chairman, department of medicine, Seton Hall College of Medicine; Mario Stefanini, associate professor of medicine and lecturer in pharmacology, Tufts University Medical School, Boston; Arnold Janzen, radiologist, Hartford; and Robert Nesbit, pathologist, Hospital of St. Raphael.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Exhibits will include those on hypersplenism, cholangiography, heart-lung machine, and electrophoresis.

LOUISIANA

General Practitioners Meeting.—The 11th annual assembly of the *Louisiana Academy of General Practice* will be held Oct. 8-10 at the Frances Hotel, Monroe. The program includes the following topics by out-of-state speakers:

Gallbladder and Duct Disease, Dr. R. L. Sanders, professor of surgery, University of Tennessee, Memphis.
Acute Abdominal Conditions, Dr. Sanders.
External Edometriosis, Dr. William F. Guerriero, clinical associate professor of obstetrics and gynecology, Southwestern Medical School, University of Texas, Dallas.
Newer Aspects in the Management and Diagnosis of Carcinoma of Female Genitalia, Dr. Guerriero.
Urology that the General Practitioner Should Know, Dr. Thomas D. Moore, professor of urological surgery, University of Tennessee.
Interpretation of Pyelograms, Dr. Moore.
Collagen Diseases, Dr. Harry E. Banghart, assistant professor of medicine, Hannemann Medical College, Philadelphia.
Osteoporosis, Dr. Banghart.

At the luncheon Dr. J. P. Culpepper, president, Southern Medical Association, will speak on "The Role of Organized Medicine," and Dr. E. S. Mc- y, chief of preceptorship program, University exas School of Medicine, Galveston, on "The dical Student and the Preceptorship." A dinner- nce will be held Oct. 7. For information write the ouisiana Academy of General Practice, 3420 Canal St., New Orleans 19, La.

MASSACHUSETTS

Hospital News.—The New England Center Hospital, Boston, has announced the establishment of a new department of infectious diseases under the direction of Dr. Louis Weinstein who, in addition to being named chief of the new unit and senior physician at the hospital, has also been appointed professor of medicine at Tufts University School of Medicine. Both the Hospital and the Medical School are part of Boston's New England Medical Center. To accept these appointments, Dr. Weinstein has resigned as chief of the Infectious Diseases Service at Haynes Memorial of the Massachusetts Memorial Hospitals and as associate professor of medicine at Boston University School of Medicine.

Personal.—Dr. James B. Dealy Jr., of Newton, has been appointed by the trustees of Peter Bent Brigham Hospital as radiologist-in-chief, succeeding Dr. Merrill C. Sosman, who has retired after more than 30 years. Dr. Dealy has served as acting radiologist-in-chief, since Dr. Sosman's retirement last July. He is also assistant clinical professor of radiology and acting chairman of the department at Harvard Medical School, Boston.—Dr. John M. Mackenzie, assistant superintendent of the Boston State Hospital and assistant professor of psychiatry, Tufts Medical School, has begun a one-year leave of absence. Under a fellowship training program, Dr. Mackenzie will hold the position of senior instructor at the University of Aberdeen Medical School in Scotland. He will teach third and fifth year undergraduates in the College of Medicine courses in psychodynamics, individual and group therapy, and the application of psychoanalysis to the major mental illnesses.

NEW JERSEY

Society News.—The New Jersey Rheumatism Association has elected the following officers: president, Dr. Irving L. Sperling, Newark; vice-president, Dr. Evelyn Merrick, Orange; treasurer, Dr. Walter R. Edwards, Trenton; and secretary, Dr. William D. Kimler, Haddon Heights.—The Essex County Pathological and Anatomical Society will celebrate its 50th anniversary Nov. 9 in Newark at the Essex House. During the day there will be a clinical-pathological program at the Martland Medical Center and in the evening Dr. Hans Popper, associate professor of pathology, Northwestern University Medical School, Chicago, will give the anniversary address.—The following officers were recently elected to the New Jersey State Gastroenterological Society: Dr. Jacob A. Riese, president; Dr. Ferdinand Weisbrod, vice-president; and Dr. Abraham Friedman, secretary-treasurer.

NEW YORK

Personal.—Dr. Martin A. Seidell, internist and neurologist, has assumed the post of medical director of J. B. Roerig and Company, New York pharmaceutical firm. Dr. Seidell, who practiced for two years at the Mayo Clinic, Rochester, Minn., joined the Roerig division of Chas. Pfizer & Co., Inc., July 15, succeeding Dr. Jerome J. Van Gasse, who has been appointed assistant general manager of Pfizer Laboratories in Brooklyn.—Dr. Charles P. Blunt, a specialist in surgery, has joined the Corning Glass Works medical staff in Corning. Dr. Blunt comes from Rupert, Idaho. Previously he was engaged in general surgery in Lynchburg, Va., from 1950-1952, and at Marion, Va., from 1952-1955.

Hospital News.—At the first reunion of former house officers of the Rochester General Hospital, Sept. 13-14, Dr. Philip Thorek, Chicago, was guest speaker. Mr. James Card, curator of movies at George Eastman House, was the banquet speaker.

Dedicate Health Department Building.—Ceremonies marking the dedication of the new State Health Department office building were held in Albany June 27. State Health Commissioner, Dr. Herman E. Hilleboe, who presided at the dedication ceremonies, introduced Governor Averell Harriman and Dr. LeRoy E. Burney, Surgeon General of the

United States Public Health Service, who were guest speakers. The new building brings together under one roof about 600 State Health Department employees who were previously housed in eight different offices and buildings throughout the city of Albany. Albany Medical College and Hospital, Albany College of Pharmacy, and the Albany Veterans Administration Hospital are nearby. The Hospital Survey and Planning Commission is housed in the building. Constructed of face brick with limestone trim, the building is "E" shaped, is completely air conditioned, and took two years to construct at a cost of $3,180,000. It includes offices of the Water Pollution Control Board and the Air Pollution Control Board. A total of 170,000 square feet of usable floor space is available within the building. The basement floor contains a cafeteria with a seating capacity of 200 people; an auditorium seating 300 people; a photography laboratory and darkroom; an exhibits workshop; and general storage and file rooms. The auditorium is available for meetings of medical societies and other health groups throughout the area.

The new office building of the New York State Department of Health.

New York City

Dr. Brunschwig Honored.—Dr. Alexander Brunschwig, New York surgeon, has received official notification of promotion to the rank of Officier in the French National Order of the Legion of Honor. By decree of the president of the Republic of France, the honor was bestowed upon Dr. Brunschwig "as a token of appreciation for the valuable services rendered by him to the cause of Franco-American cooperation in the field of medicine." Dr. Brunschwig, who was first awarded the Legion of Honor in 1950, grade Chevalier, is chief, gynecology service, Memorial Center for Cancer and Allied Diseases, and professor of surgery, Cornell University Medical College.

Personal.—Recently Dr. Louis J. Soffer, clinical professor of medicine, State University of New York College of Medicine, was awarded the Alumni Achievement medal of the University "for outstanding contributions to medicine." Previously, he was awarded the Harlow-Brooks medal by the New York Academy of Medicine. He served as a consultant of the Mount Sinai Hospital staff from 1938 to 1946 and became regional consultant, U. S. Veterans Administration in 1952.——Dr. John Caffey, professor of radiology, Columbia University College of Physicians and Surgeons, was elected honorary member of the Royal Society of Medicine at its London meeting "in recognition of his distinguished services to science."——Dr. George E. Daniels has been appointed director of the Columbia Psychoanalytic Clinic, succeeding Dr. Abram Kardiner, who has retired and accepted an appointment as lecturer in the department of psychiatry.——Dr. George T. Pack has been invited to speak at the third National Cancer Congress of the Chilean Cancer Society in November, when he will lecture on Cancer of the Stomach and the Surgical Treatment of Liver Tumors.

NORTH CAROLINA

Aging Research Grant.—A $306,922 grant for research on aging has been made to Duke University, Durham. This is the first grant in the U. S. Public Health Service's new program designed to encourage establishment of research centers in which many departments of a university and health and related agencies of a community will cooperate in studying various aspects of aging. The program at Duke University has four main objectives: (1) to develop a center for aging research based upon a university-wide effort; (2) to support fundamental research concerned with health problems of aging and to include relevant research contributions from the social and behavioral sciences and related fields; (3) to train investigators interested in the problems of aging; and (4) to foster a regional resource for the dissemination of scientific knowledge in the field of aging.

The Public Health Service's program to encourage research on aging is under the Center for Research on Aging at the National Institutes of Health, Bethesda, Md., established in October, 1956, under the direction of Dr. G. Halsey Hunt.

OHIO

Personal.—Dr. Edward A. Gall, head of the pathology department, University of Cincinnati College of Medicine, has been named editor in chief of the *American Journal of Pathology*. The journal is the official organ of the American Association of Pathologists and Bacteriologists, of which Dr. Gall is secretary.

Public Health Research Grants.—Myron Leon, Ph.D., Saint Luke's Hospital associate in surgical research, has been awarded grants by the National Institutes of Health of the Public Health Service totaling $47,100. The grants, covering a three-year period, are to be used for the study of purification and properties of complements and properdin. Dr. Leon will be assisted in these studies by two exchange fellows from Germany, Dr. Klaus Rother and Dr. Ursula Rother.

PENNSYLVANIA

Hawthorne Surgical Society.—The Hawthorne Surgical Society, an honorary fellowship of qualified surgeons who are alumni of the Graduate School of Medicine of the University of Pennsylvania, Philadelphia, will hold its fifth annual meeting Oct. 16 at the Shelburne Hotel in Atlantic City, N. J. The meeting will be addressed by Dr. Henry L. Bockus, chairman, department of medicine, University of Pennsylvania, Graduate School of Medicine. Reservations should be forwarded to Dr. Julian A. Sterling, Secretary, Hawthorne Surgical Society, 1008 Sharpless Road, Philadelphia 26, Pa.

Philadelphia

Cancer Research Grants.—U. S. Public Health Service grants totaling $38,559 have been awarded members of the faculty of the Temple University School of Medicine. The two largest grants are for cancer studies in progress under the direction of Dr. Herbert M. Stauffer, head, department of radiology, and Dr. Valy Menkin, associate professor of experimental pathology.

Personal.—The Lillian K. Synder award of the Philadelphia Allergy Society has been given to Dr. George I. Blumstein, assistant professor of immunology at the Temple University Medical Center, a paper written in conjunction with Dr. Henry [illegible], of Fairborn, Ohio. The society presents the award annually to the paper deemed most worthy from the scientific point of view.——Dr. Ernest A. Spiegel, professor of experimental and applied neurology, and Dr. Henry T. Wycis, clinical professor of neurosurgery, Temple University School of Medicine, attended the First International Congress of Neurological Sciences in Brussels, Belgium, recently, and participated in a special symposium devoted to stereotaxic operations in which they have pioneered. They reported on, "Principles and Methods of Stereoencephalotomy."

SOUTH DAKOTA

Personal.—Dr. Magni Davidson has been appointed secretary of the South Dakota Board of Medical Examiners, replacing Dr. Chester B. McVay.——Dr. George T. Jordan was presented a distinguished service award at the annual University of South Dakota Medical School Banquet recently. The award was in recognition of Dr. Jordan's many years of service devoted to clinical instruction in the field of otolaryngology and ophthalmology.

State Medical Election.—The following officers of the South Dakota State Medical Association have been installed: Dr. M. M. Morrissey, Pierre, president; Dr. Arthur A. Lampert, Rapid City, president-elect; Dr. Robert A. Buchanan, Huron, vice-president; Dr. A. P. Reading, Marion, secretary-treasurer.

GENERAL

Society News.—Officers of the National Medical Association are as follows; Dr. Arthur M. Townsend Jr., St. Louis, president; Dr. Relliford S. Smith, Macon, Ga., president-elect; Dr. Leonidas Berry, Chicago, first vice-president; and Dr. John T. Givens, Norfolk, Va., executive secretary.

Personal.—Dr. Alfred L. Copley, formerly of New York City, has accepted a position as director of experimental research in vascular diseases at the new Medical Research Laboratories, Charing Cross Hospital, part of the University of London. Dr. Copley, an experimental physiologist, has been working since 1952 in Paris, France, at first as head of the Laboratory of Physiology at the International Children's Center, and later as Chargé de Recherches of the Institut National d'Hygiéne. His work will be aided by a grant from the National Science Foundation, Washington, D. C. He will continue his investigations of the endothelium in relation to hemorrhage and of thrombosis and atherosclerosis.

Award for Laryngology Research.—Establishment of the Gould Award for Research in Laryngology was announced at the recent International Voice Conference by Dr. William E. Gould, president, William and Harriet Gould Foundation for Medical Research. The first recipient is Dr. K. Faaborg-Andersen, for his electromyographic studies of the intrinsic laryngeal muscles in humans. The board of directors of the foundation has approved specific funds for this annual award to encourage basic laryngeal research. While these funds are accumulating, the amount of the annual prize has been set at $250. An international committee will be appointed to draw up the regulations governing this award. For information write Dr. Hans V. Von Leden, Medical Director, William and Harriet Gould Foundation, 30 N. Michigan Ave., Chicago 2, Ill.

Tuberculosis Research Fellowship.—The New York Tuberculosis and Health Association has announced that the James Alexander Miller Fellowship will be available for the year starting July 1, 1958. This fellowship has been established by the association to assist a qualified investigator in medical or biological sciences who will devote full time to a research project in tuberculosis or some related problem. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the pursuit of the work. The annual stipend is $7,000. Consideration will be given to extension of the term of the fellowship at the end of the first year. Applications should be submitted in duplicate by Nov. 1. Address: the James Alexander Miller Fellowship Committee, the New York Tuberculosis and Health Association, 386 Fourth Ave., New York 16, N. Y.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Cirrhosis of the Liver.—The Metropolitan Life Insurance Company has reported that cirrhosis of the liver now ranks among the 10 leading causes of death in the United States. At ages 45-64, the only diseases which outrank cirrhosis of the liver as a cause of death are heart disease, cancer, and cerebral hemorrhage. In 1956 cirrhosis accounted for a total of about 18,000 deaths in the United States, about two-thirds of them among males. Cirrhosis of the liver shows marked geographic variations in its death rate, tending to be highest in the eastern industrial states and California, and lowest in the South and Southwest. Compared with a national average of 9.9 per 100,000 in 1950-1954, the death rate from the disease ranged from 3.7 in South Carolina to 18.5 in the District of Columbia. More than one-fourth of the deaths from the disease are reported to be associated with alcoholism, but the reporting appears incomplete. Overweight adversely influences the mortality from cirrhosis, according to insurance experience. A recent study among insured overweight men showed that the mortality from the disease was two and one-half times that of standard risks.

Occupational Health Conference.—The first annual Western Occupational Health Conference will be held Oct. 4-6 at the Biltmore Hotel, Los Angeles. The program includes the following panel discussions and moderators:

Human Factors in Engineering, Craig L. Taylor, Ph.D., University of California, Los Angeles.
Dermatological Problems in Industry, Dr. Harold Price, Los Angeles.
Hazards, Hidden and Otherwise, Mr. Jack Shanahan, safety engineer, U. S. Electric Motors, Inc.
Hiring the Handicapped Without Handicapping Industry, Dr. H. L. Herschensohn, medical director, Douglas Aircraft Co.
Radiation in Industry, Dr. Birchard M. Brundage, medical department, North American Aviation Company.
Emotional Problems in Industry, Mrs. Marion Mayne, R. N., Los Angeles County Health Department.

Guest speaker at the banquet Oct. 5 will be Mrs. Spencer Tracy, founder of the John Tracy Clinic. For information write Dr. A. C. Remington, Western Occupational Health Conference, 9851 Sepulveda Blvd., Los Angeles 45, Calif.

WEST VIRGINIA

Personal.—Dr. John N. Rich, of Huntington, chief, clinical service, Veterans Administration, Huntington, has been named superintendent of the Andrew S. Rowan Memorial Home at Sweet Springs. He succeeds Dr. Robert G. Blackwelder, of Marion, Va. Dr. Rich has served with the Veterans Administration since 1946. Prior to that time he was a member of the staff of several hospitals in Philadelphia.

University News.—Dr. Robert R. Glover, professor of thoracic surgery, Temple University, Philadelphia, will be the guest lecturer Oct. 20 at the auditorium of the Charleston General Hospital, Charleston. The lecture, "Diseases of the Coronary Arteries," is being sponsored by the West Virginia

Langlois, William Edward, Worcester, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; for many years school physician; died in St. Vincent Hospital July 5, aged 85, of chronic nephrosclerosis and uremia.

Lapp, Henry Clarence, North Tonawanda, N. Y.; University of Vermont College of Medicine, Burlington, 1897; served as city health officer and as county coroner; on the staff of the DeGraff Memorial Hospital; died June 29, aged 84, of coronary disease.

Lawrence, Frederic Mortimer, Carlisle, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1894; died in the Carlisle Hospital July 3, aged 85, of arteriosclerotic heart disease.

Lee, George Francis, Santa Clara, Calif.; Denver and Gross College of Medicine, Denver, 1909; veteran of World War II; died in the Letterman Army Hospital, San Francisco, June 1, aged 70, of bronchopneumonia and cirrhosis of the liver.

Lischer, Robert Franklin ⊕ Mascoutah, Ill.; Washington University School of Medicine, St. Louis, 1904; served on the staff of St. Elizabeth's Hospital in Belleville, where he died July 6, aged 83, of cerebral thrombosis and arteriosclerosis.

McBryde, Stewart ⊕ Arlington, Va.; Medical College of Virginia, Richmond, 1912; served overseas during World War I; on the staff of the Arlington Hospital; died July 10, aged 70, of congestive heart disease.

McCalip, William Davis ⊕ Yazoo City, Miss.; Louisville (Ky.) Medical College, 1897; veteran of World War I; died in the King's Daughters' Hospital June 26, aged 80, of diabetes mellitus and coronary decompensation.

McCutcheon, Merle D'Aubigne ⊕ East Liverpool, Ohio; College of Physicians and Surgeons, Baltimore, 1908; member of the Radiological Society of North America; veteran of World War I; associated with the East Liverpool City Hospital; died June 26, aged 72, of cancer.

McEntee, Edward James, Brooklyn; Columbia University College of Physicians and Surgeons, New York City, 1901; an associate member of the American Medical Association; fellow of the American College of Surgeons; for many years on the staff of St. Catherine's Hospital; died July 9, aged 77.

McNeel, John Osborne ⊕ St. Louis; University of Virginia Department of Medicine, Charlottesville, 1935; veteran of World War II; resigned from the U. S. Public Health Service Aug. 16, 1940; on the staff of Jewish Hospital; accidentally drowned June 19, aged 48.

Markley, Josiah Preston, Laramie, Wyo.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; veteran of World War I; died in the Veterans Administration Hospital, Cheyenne, May 20, aged 78.

Martin, Cecil Edward ⊕ Emporia, Va.; University College of Medicine, Richmond, 1909; died in the Roanoke Rapids (N. C.) Hospital May 25, aged 77, of coronary thrombosis.

Martin, Roy David, Grand Island, Neb.; University of Nebraska College of Medicine, Omaha, 1911; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; served on the staffs of the Grand Island Lutheran and St. Francis hospitals; died July 1, aged 72.

Martyn, George, Los Angeles; Licentiate in Medicine, Surgery and Midwifery of the Apothecaries' Society, 1892; L. R. C. P., of London, and M. R. C. S., of England, 1893; an associate member of the American Medical Association; died April 29, aged 88, of cerebral arteriosclerosis and thrombosis.

Melvin, Alexis Merritt ⊕ South Miami, Fla.; Jefferson Medical College of Philadelphia, 1904; served in France during World War I; died June 18, aged 76, of arteriosclerotic heart disease.

Menkel, Herman Carl, McMinnville, Ore.; Denver College of Physicians and Surgeons, 1906; for many years a medical missionary in India; died June 30, aged 82.

Mercer, Eugene LeRoy, Swarthmore, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1913; served as director of athletics and coach, Swarthmore (Pa.) College; formerly dean of the department of physical education at the University of Pennsylvania, Philadelphia; died in the University Hospital, Philadelphia, July 2, aged 68.

Minassian, Harootune Avedis ⊕ Des Moines, Iowa; Bellevue Hospital Medical College, New York City, 1887; died June 26, aged 89, of heart disease.

Moore, Moore Sr. ⊕ Memphis, Tenn.; Memphis (Tenn.) Hospital Medical College, 1898; fellow of the American College of Surgeons; for many years chief of staff, Home for Incurables; consultant, Methodist Hospital, where he died June 28, aged 80, of cerebral thrombosis.

Murphy, Edgar Watson ⊕ New Albany, Ind.; University of Louisville (Ky.) School of Medicine, 1931; died April 6, aged 55, of acute myocardial infarction.

Parker, Samuel Thomas, Pharr, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1910; died July 2, aged 70, of uremia.

Perry, Richard Wilbert ⊕ Seattle; Trinity Medical College, Toronto, Ontario, Canada, 1897; L. R. C. P., of Edinburgh, L. R. C. S., of Edinburgh and L. R. F. P. & S., of Glasgow, 1900; past-president of the King County Medical Society; charter member and past-president of the Puget Sound Academy of Ophthalmology and Otolaryngology; past-president of the Seattle Academy of Surgeons; veteran of World War I; died July 9, aged 82, of cancer.

Pyle, Jesse N., Dallas, Texas; Barnes Medical College, St. Louis, 1906; died July 2, aged 85, of cerebral thrombosis.

Rainey, Louise G., New York City; Laura Memorial Woman's Medical College, Cincinnati, 1902; died May 9, aged 89.

Rankin, Claude Bernard, Monticello, Ky.; Hospital College of Medicine, Louisville, 1898; died June 11, aged 86, of a heart attack.

Reineke, George F. ⊕ New Ulm, Minn.; University of Minnesota College of Homeopathic Medicine and Surgery, Minneapolis, 1896; specialist certified by the American Board of Otolaryngology; served on the staffs of the Loretto and Union hospitals; died May 21, aged 86, of coronary thrombosis.

Rejent, Anthony Joseph, Toledo, Ohio; St. Louis University School of Medicine, 1921; fellow of the American College of Physicians; on the staff of St. Vincent's Hospital, where he died June 23, aged 60, of coronary thrombosis.

Roach, Richard Aloysius, Santa Monica, Calif.; Northwestern University Medical School, Chicago, 1906; died in Los Angeles, June 28, aged 73, of uremia, hypertensive heart disease, and interstitial nephritis.

Robinson, Charles Irwin, Lakeland, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1910; died May 2, aged 75.

Russell, Thomas J. ⊕ Philadelphia; University of Maryland School of Medicine, Baltimore, 1910; died July 11, aged 71.

Schatz, Francis John ⊕ St. Cloud, Minn.; Jefferson Medical College of Philadelphia, 1909; died May 20, aged 74, of coronary occlusion.

Schrade, Joseph Patrick, New York City; Long Island College of Medicine, Brooklyn, 1940; veteran of World War II; died in the Veterans Administration Hospital June 28, aged 44.

Schwartz, Abraham S., New York City; Long Island College Hospital, Brooklyn, 1906; an associate member of the American Medical Association; died in the Manhattan Eye, Ear, and Throat Hospital, June 16, aged 81.

Sherwood, George Edward ⊕ Kimball, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1894; past-president of the Stearns-Benton Counties Medical Society; vice-president and director of the State Bank of Kimball; served on the staffs of the Meeker County Memorial Hospital in Litchfield and St. Cloud (Minn.) Hospital, where he died July 5, aged 85, of bilateral pneumonia.

Silver, H. Fletcher ⊕ Goldsboro, Md.; Baltimore Medical College, 1896; died in the Memorial Hospital, Easton, May 5, of carcinoma of the prostate.

Sivertsen, Andrew, Minneapolis; Marquette University School of Medicine, Milwaukee, 1916; an associate member of the American Medical Association; died in St. Barnabas Hospital June 8, aged 77, of coronary thrombosis.

Skwor, Charles James ⊕ Mishicot, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died June 20, aged 77.

Smith, James Bathurst Jr., Keysville, Va.; Medical College of Virginia, Richmond, 1926; died April 22, aged 57.

Sogge, Ludwig L. ⊕ Windom, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1905; past-president of the Minnesota State Medical Association; died July 2, aged 78, of carcinoma of the lungs.

Storey, Charles Arthur, Pasadena, Calif.; University of Wooster Medical Department, Cleveland, 1882; died July 17, aged 92.

Stratton, John Newton ⊕ Safford, Ariz.; Southwestern University Medical College, Dallas, Texas, 1907; died in the Tucson Medical Center, Tucson, June 25, aged 79, of pulmonary edema and arteriosclerotic heart disease.

Svec, Floyd Alfred ⊕ Los Angeles; Northwestern University Medical School, Chicago, 1945; interned at the Wesley Memorial Hospital, where he served a residency; served in the U. S. Naval Reserve and the U. S. Army Reserve; instructor in medicine, University of Southern California School of Medicine; on the staffs of the California Lutheran and Los Angeles General hospitals; died in Newhall, Calif., July 7, aged 40, in a traffic accident.

Taylor, Jay Richard, Brooklyn; University of Pennsylvania Department of Medicine, Philadelphia, 1878; died in the Kings County Hospital June 18, aged 100, of bronchopneumonia, pyelonephritis, and emphysema.

Taylor, John Edwin Marvin, Sparkman, Ark.; University of Arkansas School of Medicine, Little Rock, 1912; member of the American Academy of General

Practice and the Arkansas Medical Society; for many years secretary of the school board and member of the city council; died in Little Rock July 3, aged 72, of cerebral hemorrhage.

Taylor, Septimus Theodore, Alexandria, La.; Louisville (Ky.) Medical College, 1902; service member of the American Medical Association; veteran of World War I; for many years associated with Veterans Administration, retiring in June, 1949; died June 26, aged 78.

Terry, Elmer Clayton, Washington, D. C.; Howard University College of Medicine, Washington, 1916; served on the faculty of his alma mater; on the staff of the Freedmen's Hospital; died July 9, aged 70, of heart failure.

Thomas, Joseph Turner, Detroit; Meharry Medical College, Nashville, Tenn., 1905; veteran of the Spanish-American War; died June 13, aged 82.

Thompson, Leland Alexander ⊕ Springer, N. M.; University of Tennessee Medical Department, Nashville, 1908; died June 24, aged 77.

Tinsley, Will Houston ⊕ Gonzales, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1943; veteran of World War II; died March 28, aged 37, of acute coronary occlusion.

Treglown, Llewellyn Henry, Livingston, Wis.; Keokuk (Ia.) Medical College, 1897; died March 13, aged 83.

Trimble, Staunton, Burnsville, W. Va.; Baltimore Medical College, 1908; died in Weston July 5, aged 74.

Vail, William Penn, Blairstown, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; veteran of World War I; died in the Newton (N. J.) Memorial Hospital June 22, aged 77, of rupture of an aneurysm and arteriosclerosis.

Valentine, Richard Ellis ⊕ Tallula, Ill.; Louisville (Ky.) Medical College, 1904; veteran of World War I; died in the Illinois Soldiers' and Sailors' Home, Quincy, June 13, aged 76, of terminal pneumonia.

Van Metre, Richard Thompson, Fremont, Neb.; State University of Iowa College of Medicine, Iowa City, 1905; an associate member of the American Medical Association; died in Bradenton, Fla., June 13, aged 77, of cerebral hemorrhage.

Vass, Rufus Samuel, Raleigh, N. C.; Leonard Medical School, Raleigh, 1912; served on the staff of St. Agnes Hospital; died June 8, aged 70.

Visanska, Samuel A. ⊕ Atlanta, Ga.; Medical College of the State of South Carolina, Charleston, 1894; died July 18, aged 88, of a heart attack.

Weeks, Joseph Clayton Jr., Lake City, Fla.; University of Tennessee College of Medicine, Memphis, 1932; health officer of Columbia, Gilchrist, and Hamilton counties; veteran of World War II; died June 29, aged 49.

Weitzel, William Forrest, Indiana, Pa.; Baltimore Medical College, 1903; an associate member of the American Medical Association; died in the Presbyterian Hospital, Pittsburgh, June 2, aged 79, of pneumonia.

Winton, Sigmund Samuel ⊕ Chicago; University of Toronto Faculty of Medicine, Toronto, Ontario, Canada, 1939; specialist certified by the American Board of Internal Medicine; member of the American College of Cardiology; on the staffs of the Columbus Memorial, Weiss Memorial, and Michael Reese hospitals; died July 27, aged 47, of myocardial infarction, coronary thrombosis, and coronary arteriosclerosis.

White, Henry Clay, Covington, Ky.; Medical College of Ohio, Cincinnati, 1897; veteran of World War I; for many years health officer of Kenton County; died in the Veterans Administration Hospital, Cincinnati, June 29, aged 83.

White, Luther Alexander, Brooklyn; Howard University College of Medicine, Washington, D. C., 1925; veteran of World War I; died May 29, aged 67.

Williams, Frederic Nathaniel ⊕ Mount Vernon, Ind.; University of Louisville (Ky.) Medical Department, 1911; veteran of the Spanish-American War and World War I; died in the Welborn Memorial Baptist Hospital, Evansville, May 15, aged 79, of carcinoma of the duodenum with massive hemorrhage.

Williams, Sara Angela Mulvanity, Yonkers, N. Y.; Tufts College Medical School, Boston, 1908; died June 17, aged 71, of coronary occlusion.

Wilson, Isaac M., Sunset, Texas; Memphis (Tenn.) Hospital Medical College, 1900; died in Bowie May 1, aged 83.

Yawger, Nathaniel Shurtz ⊕ Philadelphia; University of Pennsylvania Medical Department, Philadelphia, 1898; specialist certified by the American Board of Psychiatry and Neurology; member of the American Psychiatric Association; died June 2, aged 84, of a cerebral vascular accident.

Young, Edward V. J. ⊕ Chicago; Illinois Medical College, Chicago, 1910; died in the Passavant Memorial Hospital July 8, aged 72, of pulmonary embolism.

FOREIGN LETTERS

INDIA

Adenocarcinoma of the Uterus.—A. Dass (*J. Obst. & Gynec. India* 7:4 [June] 1957) studied 22 patients with adenocarcinoma of the body of the uterus, half of whom fell in the age group 41 to 50 years. Thus here it appears in a younger age group than in the West. In eight of the patients in this series menopause had not occurred, although malignancy of the uterus is a disease of the postmenopausal age. This may be accounted for by the younger age group. The prognosis in younger patients is not necessarily worse than that in older patients. No rapid spread of the growth was noticed in the young patients, and they constituted better operative risks. All the patients were married except one; 10 were nulliparous. Irregular bleeding was the main symptom for which patients came to the hospital, it being present in 21. Several of these patients did not come to the hospital till about two years after the onset of the symptoms.

Of 755 patients subjected to curettage for irregular uterine bleeding in the four-year period of this study, 36 showed evidence of endometrial cancer. Obesity, diabetes, and hypertension were not commonly associated with adenocarcinoma of the uterus, as reported by others. The only constant feature that was repeatedly observed was the high incidence of either absolute or relative sterility. In one patient a diagnosis of metropathia haemorrhagica was made on curettage; later the patient was found to have malignancy of the uterus. Another patient had multiple fibromyomas with associated adenocarcinoma. Resection followed by irradiation was performed whenever possible in this series on 14 patients. Six patients were given preoperative deep x-ray therapy because of the presence of extreme sepsis in a growth protruding from the cervix. The effect of preoperative irradiation was striking in these patients. No adenocarcinoma of the uterus should be considered too advanced for treatment unless secondary metastases have developed. Four patients had irradiation only, as they were considered to be poor operative risks. No recurrence was observed after operation, although it is too early to assess the end-results.

Serum Proteins.—A. Kumar and co-workers (*Indian J. M. Sc.* 11:6 [June] 1957) made electrophoretic analyses of the serum proteins in 72 normal subjects ranging in age from 20 to 52 years. There were 53 men and 19 women, 34 of the men being professional blood donors coming from a poorer class of society. The hemoglobin value was above 13.5 Gm. per 100 ml. in each case. The value for the mean total serum proteins was 7.27 Gm. per 100 ml. with a very narrow range of variation. The albumin-globulin ratio varied from 4.95 to 0.95 with a mean of 1.70. The gamma-globulin was the highest of all the various globulin fractions. The values for gamma-globulin were significantly higher than those reported for Europeans and Americans. No significant difference was observed in the values of total serum proteins in the two sexes and in the men of different economic groups. The different protein moieties also did not show any appreciable difference in the various groups.

Poliomyelitis.—C. P. Tiwari (*Indian Practitioner*, June, 1957) studied 100 patients with paralytic poliomyelitis. The disease was more common in males (63%) than in females. Seventy-three of the patients were under 5 years of age. The onset of the disease was determined from the history. Thus in 89 patients it was judged by such symptoms as fever associated with paralysis, and in 8 it was suspected because of weakness in the lower limbs. One patient reported within one week of the onset of paralysis, but another did not report until 25 years after the onset. The most common presenting symptom was paralysis. Forty-three patients came to the hospital because of paralysis, but 46 reported only after such sequelae of paralysis as deformities and shortening had appeared. Inability to walk after 2 years of age was the complaint for which eight children were brought to the hospital. Three cases were detected incidentally during clinical examination for an unrelated complaint. Though the disease was present in all strata of society, deformities and contractures were more common in patients of the lower class. The lower extremity was involved in 80 patients, and in many of these the involvement was bilateral. There was a preponderance of involvement on the left side in both upper and lower extremities. Fixed deformities were observed in most patients. Some did not develop deformities either because of early treatment or because of total paralysis of muscles resulting in a flail joint.

Rheumatoid Arthritis.—Gour and Dutta (*J. Indian M. A.* 29:2 [July 16] 1957) studied 160 patients with rheumatoid arthritis of whom 65% were between 21 and 35 years of age. In the entire series, 36 were men and 124 were women. Swelling of interphalangeal and metacarpal joints was a common finding.

The items in these letters are contributed by regular correspondents in the various foreign countries.

The wrist, ankle, and elbow were also commonly involved. Fibrous ankylosis was present in four patients. Wasting of muscles was found in 108. The erythrocyte count and hemoglobin level were generally low. The leukocyte counts varied from 4,300 to 11,200 per cubic millimeter. Lymphocytes predominated in 116 patients and polymorphonuclear cells in 44. The sedimentation rate was invariably increased. Estimation of plasma proteins showed hypoproteinemia in 23 patients; in 36 the globulin level was increased and the albumin level was decreased. Salicylates, Irgapyrine (equal parts phenylbutazone and aminopyrine), autohemotherapy, and gold injections were given to 142 patients with not very encouraging results; 9 were treated with injections of placental serum, 7 with injections of serum from pregnant women, and 2 were given corticotropin and cortisone. The serum injections were given in doses of 6 or 7 cc. intramuscularly twice a week mixed with penicillin to prevent infection. There was definite clinical improvement after these injections; this was, however, not sustained unless the injections were continued for five or six months. The sedimentation rate came down appreciably, but the roentgenograms showed no change in spite of the clinical improvement. No untoward effects were seen.

Aortic Changes in Malnutrition.—Sriramachari and Gopalan (*Indian J. M. Sc.* 11:6 [June] 1957) studied the changes in the cardiovascular system of monkeys in which protein malnutrition was induced. Degenerative changes in the aorta characterized by mucoid degeneration of the tunica media of the aorta were observed in five of eight animals. The outstanding features were breaking up of the elastic fibers, deposition of metachromatic material (mucoid) in the interstitial spaces, and an abnormal increase in the calcium content. These changes resembled the changes observed by others during aging, hypothyroidism of long duration, and in experimental pyridoxin deficiency. In animals with such degenerative changes, the thyroid gland showed changes suggestive of hypothyroidism. Atherosclerotic lesions were not observed in any of these animals. The incidence of degenerative atherosclerotic changes as against atherosclerosis in malnourished persons should be investigated.

PERU

The Endometrium of Sterile Women.—A histochemical study of the endometrium of 43 sterile married women between 22 and 40 years of age was carried out by Mezzadra and co-workers (*Geniceologia y Obsttetricia*, vol. 3, no. 1, March, 1957). The histochemical and morphologic characteristics of about 400 samples of endometrium were examined for their glycogen, mucus, alkaline phosphatase, mucoprotein, and mucopolysaccharide content. In order to prevent inaccuracies in the results, the patients were given no local or hormonal treatment. Endometrial biopsy was performed within the 24 hours before menstruation. In 14 patients the endometrium revealed an insufficient secretion phase and in 7 an anovular cycle. Glycogen, mucopolysaccharides, and mucoprotein levels were normal in amount and distribution in relation to the time of the menstrual cycle, but the alkaline phosphotase level in both the glands and the vessels was frankly diminished.

UNITED KINGDOM

Treatment of Sickle-cell Anemia.—Sickle-cell anemia, which is inherited and has a poor prognosis, is due to a defect in the oxygenation of the hemoglobin, which, when deprived of its oxygen by the respiring tissues, undergoes a molecular rearrangement to form long rod-like particles with resulting alteration of the erythrocyte contour. The standard treatment is blood transfusion. After the discovery that zinc acetate and sodium cyanide, which are carbonic anhydrase inhibitors, prevent the in vitro sickling of washed erythrocytes from patients with sickle-cell anemia, Hilkovitz (*Brit. M. J.* 2:266, 1957) tested the action of acetazolamide on the blood of patients with this disease. The drug is a powerful although comparatively nontoxic inhibitor of carbonic anhydrase. In vitro tests showed that a concentration of 1 part in 20,000 of acetazolamide decreased the degree of sickling of blood in persons with sickle-cell anemia to almost zero. Further tests showed that it inhibits sickling by preventing oxygen loss from the hemoglobin of erythrocytes. The administration of the drug at a dosage level of 2 to 7 mg. per kilogram of body weight to a child with sickle-cell anemia reduced the percentage of sickle cells from 18.7 to 7.5 for several hours. A month's treatment with acetazolamide caused the hemoglobin to rise from 7.1 to 9.4 Gm. per 100 ml. of blood.

Attempted Suicide.—It is a legal anomaly that those who fail in suicidal attempts are guilty of a felony, while those who succeed are usually pronounced of unsound mind at coroners' inquests. In 1956, of 4,844 cases of attempted suicide known to the police (2,480 men and 2,364 women), 662 were charged. A few of these went to prison. Dr. Phyllis Epps examined 100 women sentenced to prison for attempted suicide (*Lancet* 1:182, 1957). Their ages ranged from 17 to 81 years; about 75 were under 40. The greatest number were between 20 and 29, and although many professed some form of religion, it played an unimportant part in the lives of most of them. Just under half were single, although 25% of these were cohabiting or in an involved situation, and a further 30% were worried over love affairs or illegitimate pregnancies. Only 10% of those married denied marital difficulties. An unhappy home background was common. Loneliness was a factor in many cases. In only two persons was physical disability present or contributory; another eight were pregnant, and pregnancy contributed to their depression. A history of previous mental illness was obtained from 49, and 42 had been in mental hospitals, 20 of them more than once. Thirty had been previously convicted in the courts, and 42 knew that suicide was an offense, although this did not deter them. Eleven had been charged with attempted suicide previously. A large number (90) were admitted to the hospital before appearing in court and being sentenced.

The method of attempted suicide was an overdose of drugs in 52 (barbiturates in 34 and aspirin or codeine in 18), the use of gas in 17, cutting a vein in 15, drowning in 5, poison in 3, and miscellaneous methods in 8. About 24 gave warning of their intention by letters, and 44 had made previous attempts. Forty-nine were psychoneurotic, 19 psychotic, 16 psychopathic, 11 epileptic, and 5 were borderline or mental defectives. About 24 were chronic alcoholics. In 82 cases a medical report was requested by the police. Dr. Epps states that many attempts at suicide are known to physicians but not reported to the police. The attempted suicide rate is probably six or seven times the actual suicide rate.

Blood Tests and Legitimacy.—The results of blood tests were taken as conclusive evidence by a Scottish court in a legitimacy case. A mother claimed that her child was illegitimate and not the lawful offspring of her former husband, who obtained a divorce and legal custody of their child, who was born three weeks before their marriage. The husband claimed that the child became legitimate by his subsequent marriage to the mother, who hoped to keep the child by declaring it illegitimate. Blood tests were made by two pathologists. The judge said that unless there was a case of mutation, the chances of which were only 1 in 100,000, he would accept the evidence of the tests that the child was indeed not the daughter of the divorced husband. This overruled a decree giving the custody of the child to the former husband, because custody cannot be granted to a man who is not the child's father.

Benzidine and Cancer.—At a Manchester inquest it was stated that the handling of benzidine by a 56-year-old worker led to his death. A verdict of accidental death from cancer of the bladder was returned. The man had worked for several years weighing out dye intermediates, including benzidine. He was admitted to hospital six months before his death and found at operation to be suffering from cancer of the bladder. It was stated at the inquest that until 1938 no protective clothing or pads for the mouth and nose were worn by workers in the dye industry, although some workers were given tests from time to time. A toxicologist employed by the company said that he examined exposed employees with a view to the early diagnosis of cancer of the bladder. It was only in 1941 that the carcinogenic properties of benzidine were recognized, and since then all those exposed were protected, and a new plant was designed to minimize the risk of direct contact. The deceased had been handling benzidine from 1935 to 1939, before the risk of cancer of the bladder was known.

Bronchiectasis.—A subcommittee of the antibiotics clinical trials committee of the Medical Research Council reported on the treatment of severe bronchiectasis by the prolonged administration of penicillin and oxytetracycline (*Brit. M. J.* 2:255, 1957). The patients selected were between 15 and 55 years of age. They had had symptoms for at least three months, and the bronchogram showed frank bronchiectasis affecting at least two lung segments. The sputum was either purulent or mucopurulent, and four 24-hour specimens measured at least 150 ml., or 25 ml. if mucopurulent. Observations were also made on the extent of cough, hemoptysis, dyspnea, and disability. A series of 122 patients were allocated at random to one of three forms of treatment; 38 were treated with penicillin, 44 with oxytetracycline, and 40 controls with lactose. Two 0.25 Gm. capsules were given four times a day two days a week for a year. The patients were examined regularly during this period, and measurements were made of the volume of a 24-hour sputum specimen and of the severity of cough, dyspnea, hemoptysis, and disability. As far as possible, the three groups of patients were matched for age, history of illness, and the extent of pulmonary involvement as determined bronchographically. During the year three deaths occurred, one from each group; two patients stopped treatment because they could not tolerate it, and five defaulted. Of the remaining 112 patients, 36 were treated with penicillin or lactose, respectively, and 40 with oxytetracycline. Sputum production was diminished more in the group treated with oxytetracycline than in the others. There was some reduction in the severity of cough and dyspnea in each group. There was some reduction in each group in disability, judged by the number of days' absence from work, episodes of fever, and the number of days spent in bed. No toxic effects were observed with any of the preparations. Although, in general, the results with oxytetracycline were better than with penicillin, it was considered that its increased cost would not justify its widespread use in most patients with bronchiectasis. The physicians in charge of the patients estimated that 60% of the oxytetracycline-treated group, 42% of the penicillin-treated group, and 28% of the control group improved. Much of the improvement in all groups was attributed to postural drainage.

Chronic Bronchitis.—In 1955, deaths from the effects of bronchitis in Leeds (population 508,000) numbered 463, but only 67 died from tuberculosis. Dr. Gordon Edwards and co-workers of Leeds investigated the bacterial flora of patients with chronic bronchitis and the effect on the course of the disease of (1) a preparation containing sulfadiazine, sulfathiazole, and sulfamerazine, (2) oxytetracycline, and (3) an autogenous vaccine of Hemophilus influenzae. Sputum specimens from 320 consecutive patients with chronic bronchitis revealed that nearly half were purulent, with H. influenzae and Diplococcus pneumoniae as the most commonly occurring organisms, followed by Klebsiella pneumoniae, beta-hemolytic streptococcus, and Micrococcus pyogenes var. aureus. The criteria for diagnosis were that patients should be over 20 years of age; that they should have had cough, sputum, and dyspnea for more than a year with some disability arising from them; and that there should be no evidence of other causes for these symptoms. Sixty-six patients (57 men and 9 women) aged 28 to 71 years were admitted to the trial. Each patient was given 1.5 Gm. daily of oxytetracycline, or the sulfonamides, or a course of injections of the vaccine, starting with 100 million bacilli and increasing to a maximum of 2 billion organisms. The oxytetracycline and sulfonamides were given until the sputum became mucoid, and then the dose of each was reduced to 1 Gm. daily. Inert tablets were also used as controls. Treatment was continued for six months.

Two bacteriologists allotted patients to different treatment groups by random selection after balancing for sex and age. Final assessment was made from sputum changes (volume and purulence), respiratory disability (determined by work category), physical disability (colds or acute exacerbations of the chest condition), general health, and bacteria in the sputum. In addition a complete blood count, sedimentation rate, vital capacity determination, and a roentgenogram of the chest were made and body weight and chest expansion recorded. Two of the patients died, one from coronary thrombosis and the other from congestive heart failure, and 11 patients dropped out of the trial. This left 53. Statistical analysis of the data obtained at the end of the trial showed without doubt the clinical value of the continuous administration of oxytetracycline to patients with chronic bronchitis. Marked improvement followed the use of this drug, and the results were enhanced by the simultaneous use of sulfonamides. The use of the sulfonamides alone was of little clinical value, and the autogenous vaccine gave no benefit. Although H. influenzae and D. pneumoniae were the predominating pathogens, no significant change could be detected in the potentially pathogenic flora of bronchitic sputums after effective antibacterial drug treatment. It is possible that the value of the latter lies in preventing superinfection of the bronchial tree rather than by direct action on the established bacterial flora of the bronchi.

Research in Anesthesia.—The new department of anesthesia which opened at the Royal College of Surgeons, London, is the only department of anesthesia research in the country relieved of the responsibilities of teaching medical undergraduates and of providing a hospital anesthesia service. Clinical work is performed by members of the staff, who hold honorary appointments in some of the London hospitals. Postgraduate teaching is done in the department. The staff includes not only anesthetists but also physicists and other scientific workers. Two of the main research problems are hypothermia in experimental animals and human respiration under anesthesia. The department has been subsidized by generous gifts from the pharmaceutical industry.

Medical Etiquette.—In the opening article of the symposium on medical etiquette (*The Practitioner*, July, 1957), Dr. C. A. Clarke stated that there is no doubt that a deterioration has occurred in the relations between the family physician and the consultant since the introduction of the National Health Service for the following reasons: 1. There is a growing tendency for the family physician to lose patients, in the sense that, although they remain on his list, they are not his patients, treatment and advice always being given by somebody else. There seem to be too many special clinics for common conditions, all having too extensive a follow-up, so that patients tend never to get permanently discharged back to their own doctors. Consequently, the patients come to regard the hospital staff, and not the family physician, as their advisers. The young physician may become discouraged when he finds all he is left with are some incurable patients with psychoneuroses and chronic bronchitis. 2. Consultants in the National Health Service are paid at a much higher rate and are not so dependent as they used to be on the general practitioner for their livelihood. 3. All physicians have too much routine work to do. Most of them are either chasing full lists or full office hours. Dr. Clarke particularly criticizes the abuse of the system of domiciliary visits, i. e., the system whereby a consultant is paid $11.75 for each visit he pays to a National Health Service patient at the request of the patient's family physician. He cites the following example of what happens. A general practitioner saw a patient with a consultant, and two weeks after the original consultation he received a letter from the consultant saying that the latter had looked in again on the patient. He reported some findings and enclosed a second domiciliary visit form to be signed by the practitioner and returned to him. The reaction of the practitioner can well be imagined. In the old days when you saw two physicians talking to each other it was usually about their patients; now they are discussing how much money they can make out of the Health Service.

The Hippocratic Oath and the rules as laid down by the British Medical Association ethical committee are largely outdated in their details, according to Dr. A. L. Potter. He quotes the following example of an outdated rule: "Except in emergency, an industrial medical officer shall not undertake any treatment that is normally the responsibility of the employee's own doctor, unless it be with his agreement." As, on an average, there are 350 visits a day in the casualty departments in the factories with which he is concerned, Dr. Potter believes that a great waste of money, time, and medical, nursing, and clerical effort would result if this rule were strictly adhered to. It has proved much easier to obtain the cooperation of all the practitioners in the area and their agreement to his treating their patients by inviting them to come to the factories and see how the medical department works.

"A Bluebook Full of Whitewash."—In a pamphlet published by the Fellowship for Freedom in Medicine, the description "a bluebook full of whitewash" has been applied to the Guillebaud report on the National Health Service—the late Lord Horder's gallant rearguard action against the National Health Service and the only medical organization in the country with the specific aim of protecting the public and the medical profession from state monopoly in medicine. The Guillebaud committee was appointed by the Minister of Health in 1953 to suggest means of insuring the efficient use of the funds available to the Health Service and to make recommendations for avoiding a rising charge on the exchequer. In its report, published last year, the committee stated, "We have found no opportunity for making recommendations which would produce new sources of income or reduce in a substantial degree the annual cost of the Service." It is this complacent conclusion that is assailed in the pamphlet. The fellowship points out that the committee seeks to attribute some of the strains and stresses of the service to the difficulty experienced by many who had grown up under the old system in adjusting themselves to the new. To this it adds what appears to be an ominous suggestion that "the gradual emergence of a new generation"—one, presumably, to which the time honored ideal of service to medicine rather than to the state is unfamiliar—"may make comparatively simple many things which now appear difficult—or impracticable."

The fellowship has two major criticisms of the Guillebaud report. The first is that no constructive suggestions were put forward for transferring more work from the hospitals to general practitioners and thereby reducing the cost of the Service and improving the standard of general practice. The second is that there were no constructive recommendations for dealing with the present division of the Service into three watertight divisions—the hospital and specialist services, the general pratitioner services, and the local authority services. The fellowship's proposal for dealing with this unfortunate state of affairs is that the three parts of the Service should be fused at national, regional, and local levels. On the top story would be a national health board which would be responsible to the Minister of Health for preparing an annual budget, for the general administration of the Service, and for keeping a proper balance between the different parts of it. The work would be decentralized through regional and local health councils, which in their turn would have similar responsibility, including the disbursement of funds made available to them on the basis of budgets they had submitted. A further important advantage claimed for the establishment of such a board is that it would remove the Service from party politics.

The fellowship advances the following suggestions for the more efficient running of the Service: restoration of the physician's right to buy and sell the goodwill of practices; the imposition of a board and lodging charge for patients in hospitals; the raising of the charge on prescriptions; the introduction of the Australian method of providing essential drugs free and charging for the rest; the decentralization of financial control of hospitals by the adoption of a system of block grants for current expenditure; the placing of some responsibility on patients by imposing a small charge, at the time services are received, on those who can afford to pay; and lowering of the cost of private beds so as to attract more paying patients. The fellowship believes that the report leaves a strong impression that in its desire to avoid embarrassing the Ministry advisers, the committee shrank from proposals that might appear to disparage the present system. Unless due consideration is given to the manifest shortcomings of the report, it is almost certain that a succession of Health Ministers will use it as a shield behind which to hide in resisting attempts to bring about the major reorganization of the National Health Service which experience has shown to be so urgently needed.

CORRESPONDENCE

INTRACUTANEOUS ADMINISTRATION OF ASIAN INFLUENZA VACCINE

To the Editor:—Previous experiences with the intracutaneous method of immunization introduced originally by me for typhoid vaccine and later applied to other antigens (*J. A. M. A.* 164:1626 [Aug. 3] 1957) make it quite natural for the question to be raised as to whether this method could be applied in the immunization of individuals with the Asian influenza virus vaccine. I have been asked this question by several physicians with the objectives in mind of conserving the vaccine supply and of minimizing reactions. Previous experiments with vaccines prepared from strains of influenza virus other than the Asian have shown that an intracutaneous injection of 0.1 ml. of such a vaccine induces a degree of immunity in terms of antiviral antibody comparable to that provided by a subcutaneous injection of 1.0 ml.

Because the Asian strain is new to the United States, sufficient time has not elapsed to determine whether this also would be true of a vaccine prepared from this strain. However, after inquiry in various laboratories, it was learned that some preliminary experiments have been carried out by Dr. Maurice Hilleman, chief of the department of respiratory diseases, Walter Reed Army Institute of Research in Washington, D. C. After a personal conversation with him concerning the results of these experiments, Dr. Hilleman offered the following information, based on a small series of tests, which is being summarized with his permission: "the amount of antiviral antibody as measured by the hemagglutination technique engendered by intracutaneous injection of 0.1 ml. (containing 16 units of Asiatic 'flu' virus vaccine) was almost but not quite as good as that which followed subcutaneous injection of 1.0 ml. (containing 160 units). Therefore, where the supply is plentiful, the subcutaneous injection of 1.0 ml. is to be preferred. But, if the supply is short and conservation of it is necessary, then the injections may be given intracutaneously with the knowledge that the smaller dose will induce a level of antibody protection which approximates that of 1.0 ml. subcutaneously."

I am in agreement with the latter opinion expressed by Dr. Hilleman. I believe, therefore, that the vaccine should be administered subcutaneously in doses up to 1.0 ml. (depending upon age and weight) so long as the vaccine supply is adequate. If not, it can be given intracutaneously (and it is important that the entire dose be given into and not beneath the skin) in doses of 0.05 to 0.1 ml. (the former for young children, the latter for older children and adults). This method, likewise, can be utilized in those patients in whom the occurrence of a general or constitutional reaction (e. g., fever, chills, etc.) which occasionally follows subcutaneous injections might be detrimental to their condition, as for example in patients with general debility or cardiovascular disease. Since the immunity which follows injection of the influenza virus vaccine is variable in degree and temporary in duration, lasting for periods averaging perhaps four to six months, it might be well to give an additional booster dose of 0.05 to 0.1 ml. intracutaneously four or more months after the administration of the initial dose to those individuals who are being exposed to the disease at that time (in the event of an epidemic outbreak) or are likely to be exposed to the disease if it is still active in their community. Such administration can do no harm; in fact, it may be instrumental in stimulating the waning immunity induced by the initial injection at a time when they need it most and might help to prevent the complicating respiratory infections prevalent especially during the winter months.

ALLERGY TO INSULIN

To the Editor:—The article on tolbutamide (Orinase) that appeared in The Journal under New and Nonofficial Drugs (164:1333 [July 20] 1957) was very informative. The indications and contraindications were well presented, but one important point, namely, allergy to insulin in diabetics, was not mentioned. Diabetics who find it difficult or impossible to use insulin due to severe local and general manifestations (about 14% of all diabetics, according to Urbach and Gottlieb: Allergy, ed. 2, New York, Grune & Stratton, Inc., 1946, pp. 344-346) are often referred to allergists. This allergy generally affects patients in the middle-aged or older group, the age group most suitably treated with tolbutamide. Therefore, where allergy to insulin is persistent, this drug may be of extreme value.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Hospital's Liability for Negligent Acts of Its Employees.—This was an action for damages for personal injuries resulting from the alleged negligence of the defendant physician and the defendant hospital. There was a verdict against both defendants and the hospital appealed to the court of appeals of New York.

The plaintiff entered the defendant hospital for correction, by her own physician, of a fissure of the anus. She had been made ready for the operation, before the surgeon's appearance, by the hospital anesthetist and by two nurses also in the employ of the hospital. Preparatory to administering spinal anesthesia, the anesthetist painted the lumbar region of the patient's back with an alcoholic antiseptic, tincture of Zephiran, an inflammable fluid, reddish in color. Again, after induction of the spinal anesthesia, one of the nurses applied the Zephiran solution to the operative area. At that time there were three layers of sheeting under the patient. The nurses were fully aware that the inflammable antiseptic employed was potentially dangerous. They acknowledged that they had been instructed not only to exercise care to see that none of the fluid dropped on the linen but to inspect it and remove any that had become stained or contaminated. However, they made no inspection, and the sheets originally placed under the patient remained on the table throughout the operation. The surgeon was not in the operating room when the antiseptic was applied and at least 15 minutes elapsed before he initiated the preoperative draping process. The draping completed, the doctor took a heated electric cautery and touched it to the fissure to mark it before beginning the actual searing of the tissue. There was a "smell of very hot singed linen" and, "without waiting to see a flame or smoke," he doused the area with water. Assured that the fire was out, he proceeded with the operation. Subsequent examination of the patient revealed severe burns on her body and later inspection of the linen revealed several holes burned through the sheet under her.

As is apparent, said the court of appeals, the liability asserted against the hospital is predicated on an independent act or omission of the hospital-employed nurses, and not on any conduct of theirs ordered or directed by a visiting doctor or surgeon or, for that matter, by any physician. The evidence strongly supports the findings, implicit in the jury's verdict, that some of the inflammable Zephiran solution had dropped on the sheet beneath the plaintiff's body, that it had left a stain discoverable upon inspection, that the nurses in attendance had had full opportunity, before the beginning of the operation, to remove the stained linen and that the solution, which had dropped on the sheet, had given off gaseous vapor that ignited upon contact with the heated cautery. In the light of these facts, the jury was thoroughly justified in concluding that the failure of the nurses to remove the contaminated vapor-producing linen constituted the plainest sort of negligence. The hospital contended, however, that such negligence occurred during the performance of a "medical" act and, accordingly, under the so-called Schloendorff rule, the doctrine of *respondeat superior* may not be applied to subject it to liability.

The court of appeals admitted that there had been a great deal of difficulty in differentiating between the "medical" and the "administrative" in applying the Schloendorff rule. It refused to do so in this case but, instead, decided to review the rule itself. The distinctions necessary under the rule were the result of "a judicial policy of compromise between the doctrines of *respondeat superior* and total immunity for charitable institutions." The court, therefore, reviewed the basis for the immunity rule and concluded that it is no longer supportable. The doctrine of *respondeat superior*, said the court, is grounded on firm principles of law and justice. Liability is the rule, immunity the exception. It is not too much to expect that those who serve and minister to members of the public should do so, as do all others, subject to that principle and within the obligation not to injure through carelessness. It is not alone good morals but sound law that individuals and organizations should be just before they are generous, and there is no reason why that should not apply to charitable hospitals. The concept that the hospital does not undertake to treat the patient, does not undertake to act through its doctors and nurses, but undertakes instead simply to procure them to act upon their own responsibility, no longer reflects the facts, the court continued. Present-day hospitals, as their manner of operation plainly demonstrates, do far more than furnish facilities for treatment. They regularly employ on a salary basis a large staff of physicians, nurses and interns, as well as administrative and manual workers, and they charge patients for medical care and treatment, collecting for such services, if necessary, by legal action. Certainly, the person who avails himself of "hospital facilities" expects that the hospital will attempt to cure him, not that its nurses or other employees will act on their own responsibility. Hospitals should, in short, shoulder the responsibilities borne by everyone else. There is no reason to continue their exemption from the universal rule of *respondeat superior*. The test should be, for these institutions, whether charitable or profit-making, as it is for every other employer, was the person who committed the negligent injury-producing act one of its employees and, if he was, was he acting within the scope of his employment.

The court of appeals accordingly held that the rule of nonliability is out of tune with the life about us and that it should be abandoned. The judgment of the appellate division in favor of the defendant hospital was therefore reversed and the case remanded for a new trial.—*Bing v. Thunig, 143 NE (2) 3 (New York, 1957).*

Malpractice: Standard of Care Required of Dentist.—This was an action for injuries caused by the alleged negligence of the defendant dentist. From a judgment of nonsuit, the plaintiff appealed to the Supreme Court of North Carolina.

In extracting two of the plaintiff's upper molars the defendant broke off the roots, probed for them, but left them imbedded in the jaw bone. Three or four days later the plaintiff returned to the defendant's office in great pain. The defendant at that time opened the infected area and drained a considerable amount of pus and blood. This treatment was repeated two or three times a week over a period of five months. When these treatments failed to clear up the condition, the plaintiff consulted specialists in the eye, ear, nose, and throat who hospitalized her and surgically removed the roots. One of these specialists, testifying for the plaintiff, stated that it is accepted practice to remove a root fragment following an extraction unless only a flake is left. More than a flake was left in the plaintiff's jawbone, however.

A dentist, said the supreme court, is liable if injury approximately results from a want of skill or from a want of its application. One who holds himself out to practice dentistry, by implication agrees to bring to his patient's case a fair, reasonable, and competent degree of skill and to apply that skill with ordinary care and diligence in the exercise of his best judgment. The dentist does not have to possess extraordinary skill and learning nor does he have to exercise the highest possible degree of care. He is liable, however, if there is a want of ordinary and reasonable care which leads to a bad result. There was expert testimony for the plaintiff that broken roots should be removed at the time of the extraction. That infection in and around the broken roots should be allowed to continue for five months with two or three weekly treatments which did nothing more than drain the infected area, would, said the court, seem to be enough to permit the plaintiff to submit her case to the jury. Accordingly, the judgment of nonsuit in favor of the defendant dentist was reversed. *Hazelwood v. Adams, 95 S.E. (2d) 917 (N. C., 1957).*

MEDICAL FILM REVIEWS

The Hepato-Jugular Reflux: A Helpful Sign in Diagnosis and Treatment of Congestive Heart Failure: 16 mm., color, sound, showing time 15 minutes. Prepared by J. Marion Bryant, M.D., New York. Procurable on loan from Wyeth Laboratories, Philadelphia 1.

The purpose of this film is to demonstrate the bedside use of the hepatojugular reflux and to give a simplified explanation of the reflux's significance in the diagnosis and treatment of congestive heart failure. This distention of the neck veins when pressure is applied over the liver is a physical sign of congestive heart failure which appears much earlier than the conventional classic signs and symptoms of heart failure. It was originally described by William Pasteur in 1885, and subsequently has been mentioned in many textbooks and articles. However, detailed instructions to enable the practitioner to use this maneuver are not available at present in the medical literature. This is an unusually good film which is self-explanatory. The photography is excellent and the direction and organization are superior. It is highly recommended for general practitioners and also would be of interest to cardiologists, internists, medical students, residents, and interns who have not had recent reviews on the subject.

Immediate Postoperative Care: 16 mm., color, sound, showing time 27 minutes. Prepared by Frank Glenn, M.D., John M. Beal, M.D., and Joseph Artusio Jr., M.D., New York. Produced in 1956 by Billy Burke Productions, Hollywood, for and procurable on loan from E. R. Squibb and Sons, Division of Olin Mathieson Chemical Corporation, 745 Fifth Ave., New York 22.

This film shows a wide variety of procedures, equipment, drugs, and special skills required to provide patients with the same caliber of care during the immediate postoperative period that they received during the operation. The film begins with scenes that apply to all patients: maintenance of a clear airway; observation of vital signs; various techniques of providing oxygen; control of pain; fluid therapy and blood replacement; the use of suction; and special recovery room procedures and records. Then portions of different surgical procedures such as urologic, intrathoracic, gastrointestinal, biliary tract, and others are shown to help the viewer understand the reason for the related recovery room procedures described. The subject is presented more from the standpoint of scope rather than actual techniques. The color photography and narration are excellent; however some of the surgical techniques should have been omitted, and more of the more common techniques of the postoperative period could have been illustrated. The film is suitable for showing to medical students, nurses, interns, residents, hospital administrators, and surgeons.

ILLUSTRATED FILM REVIEWS

Illustrated reviews of current films will appear when possible as a regular feature in The Journal. *They will consist of an introduction by the author followed by a pictorial digest of actual frame enlargements selected as key points of the film. The written review of this film appears on page 280 of this issue.*

THE HEPATO-JUGULAR REFLUX

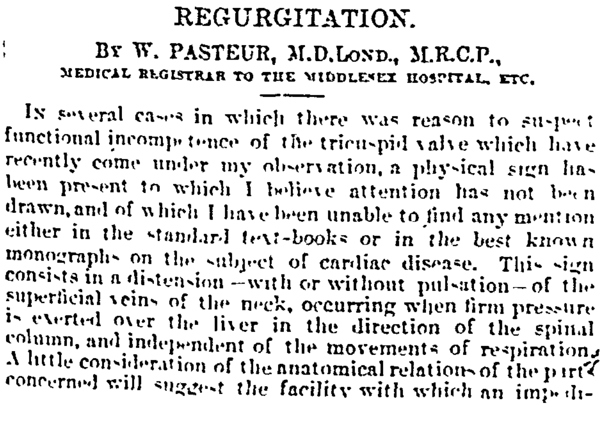
A HELPFUL SIGN IN THE DIAGNOSIS AND TREATMENT OF CONGESTIVE HEART FAILURE

J. Marion Bryant, M.D., New York

The hepatojugular reflux is a reliable but neglected physical sign which appears earlier in the course of congestive heart failure than the conventional signs and symptoms. In 1885, Pasteur originally described this sign as a manifestation of tricuspid regurgitation. However, experience has shown that it is present with heart failure of all etiologies.

The hepatojugular reflux, as presently defined, consists of a distention of the neck veins when pressure is applied over the liver. With a competent heart, pressure on the liver does not elevate the venous blood level in the neck veins when the subjects are in the semirecumbent position. The competent heart promptly increases its output, in response to an increase in venous return, and thus prevents a rise in general venous pressure. In the presence of congestive heart failure, pressure applied to the liver causes a sustained rise of the venous pressure that is prominently reflected by distention of the superficial, and elevation of the pulsating level of the deep, neck veins. The impaired heart is unable to respond to an increase in venous return by an increase in its output; therefore, the venous pressure rises.

Measurements of venous pressure, per se, may not unequivocally disclose minor grades of heart failure. However, the hepatojugular reflux will often indicate the presence of failure before symptoms or other signs become obvious. The disappearance or diminution of the hepatojugular reflux provides a practical end-point of optimal or maximum therapeutic effect.



NOTE ON A
NEW PHYSICAL SIGN OF TRICUSPID REGURGITATION.

BY W. PASTEUR, M.D.LOND., M.R.C.P.,
MEDICAL REGISTRAR TO THE MIDDLESEX HOSPITAL, ETC.

IN several cases in which there was reason to suspect functional incompetence of the tricuspid valve which have recently come under my observation, a physical sign has been present to which I believe attention has not been drawn, and of which I have been unable to find any mention either in the standard text-books or in the best known monographs on the subject of cardiac disease. This sign consists in a distension—with or without pulsation—of the superficial veins of the neck, occurring when firm pressure is exerted over the liver in the direction of the spinal column, and independent of the movements of respiration. A little consideration of the anatomical relations of the parts concerned will suggest the facility with which an impedi-

Fig. 1.—The hepatojugular reflux was originally reported as a manifestation of tricuspid regurgitation by William Pasteur.

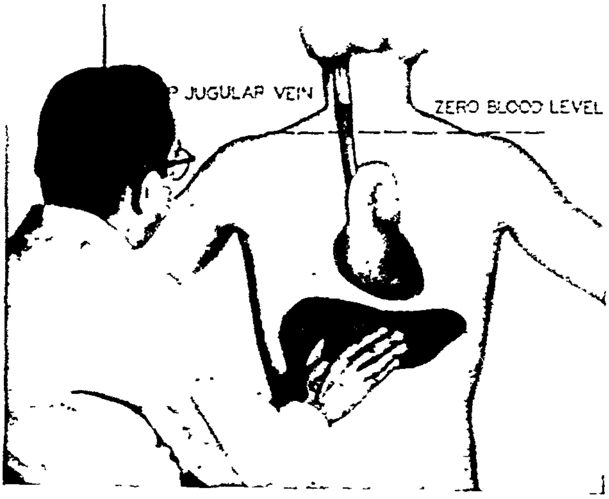


Fig. 2.—This sign consists of an elevation of the pulsating level in the deep neck veins or distention of the superficial neck veins when pressure is exerted over the liver.

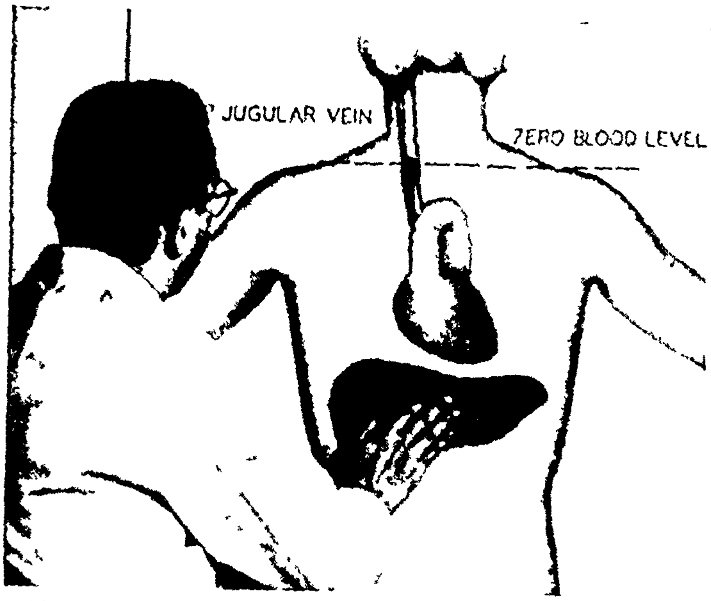

Fig. 3.—In the normal subject, pressure applied to the liver does not cause a rise in the venous blood level.

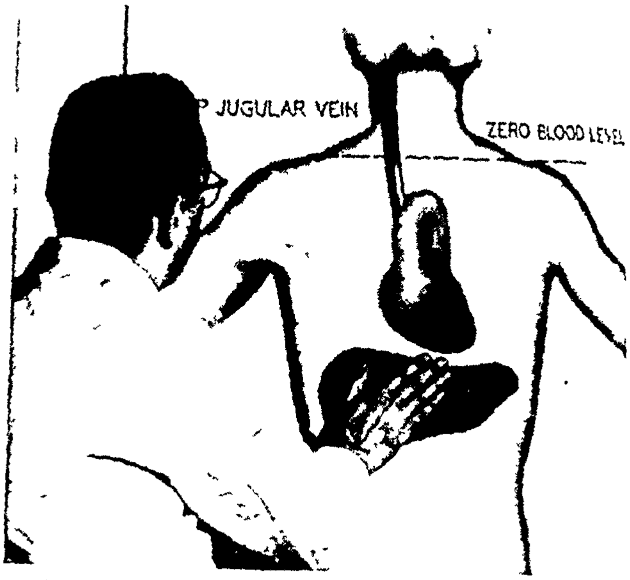

Fig. 4.—With heart failure, pressure on the congested liver produces a sustained rise of the venous level in the neck veins.

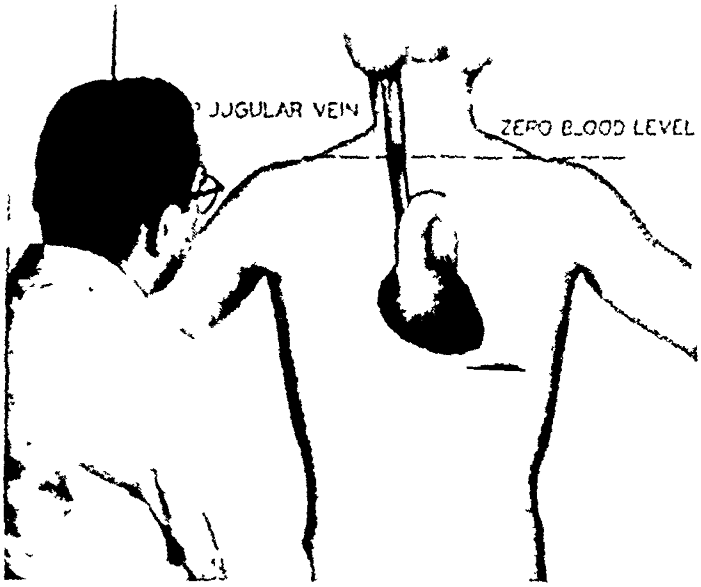

Fig. 5.—As pressure on the liver is released the venous level falls.

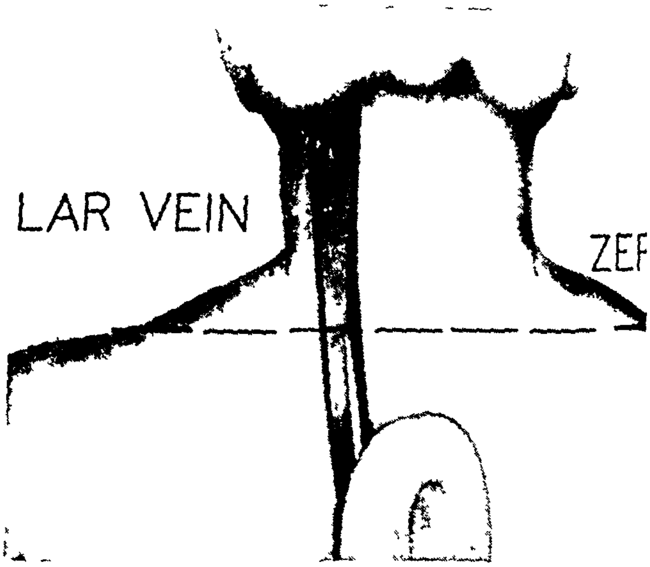

Fig. 6.—A close-up view of the neck during hepatic pressure demonstrates distention of the veins with the subject in the upright position. The motion picture shows the superior portion of the blood column in the deep veins pulsating

Fig. 7.—Venous pulsation is most commonly limited to the internal jugular veins and is recognized by the character of the movement communicated to the structures covering the veins.

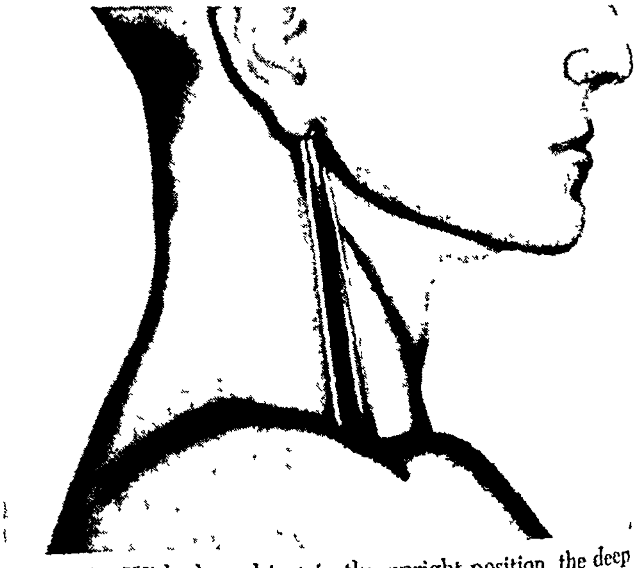

Fig. 8.—With the subject in the upright position, the deep vein pulse has a simple up-and-down movement, rather than a true expansile pulsation.

Fig. 9.—With the subject in the supine position the deep neck veins acquire a rippling, wave-like motion along the entire length of the neck.

Fig. 10.—Careful positioning and observation will demonstrate venous pulsations in most patients.

Fig. 11.—Venous and arterial pulsations are easily differentiated. The venous pulse can be eliminated by applying gentle pressure at the base of the neck without disturbing the arterial pulsations.

Fig. 12.—Elevation of the patient is followed by emptying of the superficial veins, during which the deep vein pulsations move from the jaw to the clavicle.

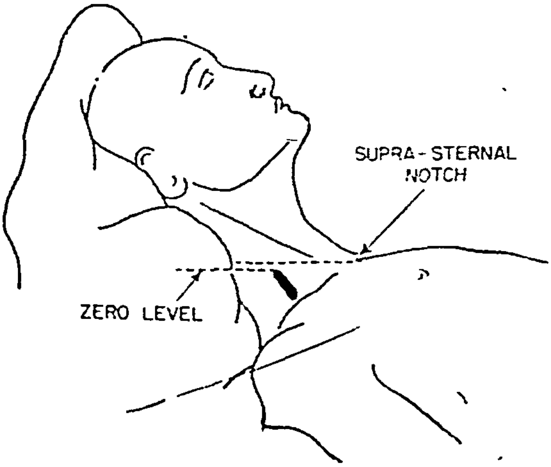

Fig. 13.—Diagram of the supine subject shows that the normal venous zero level lies a little below the suprasternal notch. (From Lewis, T.: Diseases of Heart, ed. 4, London, Macmillan & Co., 1946.)

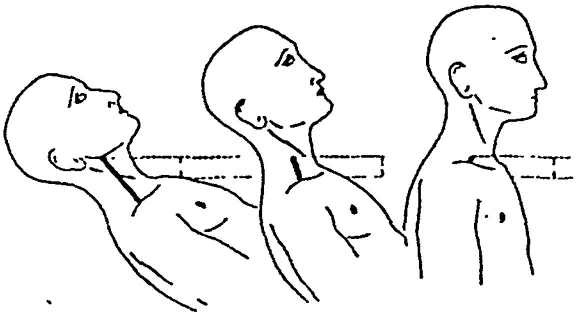

Fig. 14.—With an elevated venous pressure, the vertical distance between the blood level and the suprasternal notch is more or less the same in the semirecumbent, the semisitting, and the upright positions.

those with a negative reaction to the L. E. test were essentially alike. Pathognomonic features of systemic lupus erythematosus were not observed in any patient.

The evidence presented in this study indicates that the L. E. phenonmenon may occur in patients with rheumatoid arthritis as a nonspecific reaction of unknown causation. The diagnosis of systemic lupus erythematosus should not be made in patients with rheumatoid arthritis who have a positive reaction to the L. E. test unless it can be confirmed by other evidence. The prognosis and choice of therapy in such patients should not be based on the results of a single laboratory examination.

Successful Electrical Stimulation of the Heart for 90 Hours in Adams-Stokes Disease. G. Friese. München. med. Wchnschr. 99:811-813 (May 31) 1957 (In German) [Munich, Germany].

The case of a 65-year-old woman with hypertension and myocardial insufficiency is presented. Disturbances in the atrioventricular conduction system caused repeated Adams-Stokes attacks. At first these attacks could be controlled by the administration of sympathicomimetic drugs, but later they became ineffective, and so an electrical pacemaker was used for prolonged periods, for 61 hours, 90 hours, and 14 hours, every time the woman seemed to become moribund. The patient improved under the combined use of the electrical pacemaker and cardiac stimulants. Three months after she was dismissed from the hospital, she was free from cardiac symptoms. The author mentions several investigators who have developed cardiac pacemakers. The one he used in the woman presented here has so far been used effectively in 4 patients.

He believes that the use of the electrical pacemaker is indicated in cardiac arrest of extreme bradycardia in Adams-Stokes disease; in cardiac arrest after exposure to high tension current; in cardiac arrest after defibrillation; in cardiac arrest resulting from excessive doses of digitalis or procaine amide; and during the so-called reflex arrest occurring after surgical and endoscopic interventions. Not every dying heart, however, is amenable to the use of the electrical pacemaker, but only those in which the contractility is still preserved. In patients with Adams-Stokes attacks the pacemaker should be used also when the ventricular automatism has not as yet completely subsided but is so slow that it is not capable of furnishing a minute volume necessary for the preservation of life.

Diagnosis and Differential Diagnosis of Atrial Septal Defects. O. Bayer. Schweiz. med. Wchnschr. 87:535-540 (May 4) 1957 (In German) [Basel, Switzerland].

Bayer emphasizes the fact that the clinical diagnosis of an atrial septal defect has not been made as frequently in the past as one would have expected according to the high incidence of this defect revealed by anatomicopathological reports. There are 3 types of atrial septal defect which must be distinguished anatomically, namely, the persistent ostium secund in the upper portion of the atrial septum, the i dence of which is predominant; the persistent os primum in the basal portion of the septum; and t common atrioventricular canal. The atrial septal d fect, and particularly the persistent ostium secund is frequently associated with a transposition of or several of the pulmonary veins. Hemodyna changes and particularly the heavy extra volume l placed on the right side of the heart and the over ing of the pulmonary circulation determine the cl ical symptomatology of the atrial septal defect. Cya sis may be absent in patients with an uncomplica atrial septal defect or may occur only in the m advanced stages of the disease. Besides the prese of the typical murmur, it is the roentgenogram wh reveals characteristic changes such as enlargement the right side of the heart, the typical prominence the pulmonary arch, and the strongly increased tr ings of the pulmonary vessels with increased auto mous pulsation of the hilar vessels. The electrocard graphic findings vary with the size and the type the defect. Catheterization of the heart is indispe sable for establishing the diagnosis and for the d termination of the shunt volume. Analysis of t pressure curves of the left and the right atrium is considerable aid in the determination of the size the defect. Differential diagnosis of an atrial sep defect from an isolated partial transposition of p monary veins is most difficult. The methods wh have been devised for this purpose, such as the i jection of dyes in the left and right pulmonary teries or the blockade of the right branch of t pulmonary artery with a balloon sound, are eit technically difficult or are associated with a cert factor of insecurity. An exact quantitative diagnosis necessary because of the importance and the serio ness of the surgical intervention.

Experience with the Course and Chemotherap Chronic Pulmonary Histoplasmosis. W. D. Sutl Am. Rev. Tuberc. 75:912-920 (June) 1957 [New Yor

Of 23 men between the ages of 33 and 73 ye with chronic pulmonary histoplasmosis, the diagno was established by cultures of Histoplasma capsu tum from the sputum in 19, and tissue removed operation was the source of H. capsulatum in the remaining patients. The most frequent sympto were cough, mucopurulent sputum, weight loss, che pain, weakness or fatigue, fever, dyspnea on exertio and bloody sputum, in that order. Detailed repo of the cases of 2 patients, 1 with gradual onset and with advanced pulmonary changes, illustrate the ea and the late manifestations of the disease. In the fir patient, the roentgenogram taken at the onset show the development of a very small infiltration; a slig increase in the infiltration appeared 13 months aft the onset, and 20 months after the onset an annul shadow 3 cm. in diameter with a thin wall was see at the level of the second anterior rib with infiltratio tending in a linear manner to the hilum. Calcified dules were present in the hilum and in the lung renchyma. In the second patient, the roentgeno- am taken 15 months after the onset of the disease owed bilateral apical fibrous lesions with multiple vities 1 to 3 cm. in diameter; calcified nodules were esent in both lung fields, both hili, and in the spleen. Surgical and antimicrobial therapy were used sys- matically in attempts to influence favorably the herwise fairly uniform course of the disease. Ex- sion of the area of abnormal tissue was performed 8 patients. Ethyl vanillate in doses of 50 mg. orally r day was given to 5 patients, β-diethyl-aminoethyl- ncholate in doses of 150 to 600 mg. intravenously r day to 7 patients, nystatin to 4 patients, and acti- one, 2-aminostilbamidine, and cycloserine to 1 each. efinite improvement was noted after β-diethyl- ninoethyl-fencholate therapy in 1 patient with rela- vely mild chronic pulmonary histoplasmosis. Dis- minated histoplasmosis was arrested in 2 patients ter treatment, one of whom was given ethyl vanil- te, and the other was given β-diethyl-aminoethyl- ncholate. Toxic symptoms limited the use of all of ese agents in varying degrees. A general conclusion as reached that more potent and less toxic antifungal gents were needed for adequate favorable thera- eutic effect in patients with chronic pulmonary histo- lasmosis.

valuation of Clinical Aids to the Diagnosis of hronic Progressive Cavitary Histoplasmosis. P. H. ehan, C. A. Brasher, H. W. Larsh and M. L. Furco- ow. Am. Rev. Tuberc. 75:938-948 (June) 1957 [New ork].

Of 130 patients with a positive reaction to serologic ests for histoplasmosis (called "serologically proved"), he diagnosis of cavitary histoplasmosis was confirmed y mycologic studies in 33. The observations made in hese 33 cases and in 10 additional mycologically roved cases from another study indicate that the linical and roentgenographic features of cavitary istoplasmosis are indistinguishable from those of avitary tuberculosis. The skin test and the serologic ests for histoplamosis are useful screening aids, but ach has its limitations. Approximately 25% of known patients are nonreactors to the skin test. At least 10% have negative reactions to the serologic tests employed. In the light of these findings it is evident that negative results from a skin or serologic test for histoplasmosis do not exclude the diagnosis of histoplasmosis.

Concomitant infections with Mycobacterium tuberculosis and Histoplasma capsulatum are not uncommon and should be searched for. Such infections may account for some of the failures in the chemotherapy of tuberculosis. Mycologic studies of the sputum in proved cases reveal that H. capsulatum can be readily and repeatedly isolated in these cases. Adequate pathological studies using special fungal stains are necessary to exclude a fungal cause.

SURGERY

A Clinicopathologic Study of Large Benign Gastric Ulcers. J. C. Turner Jr., M. B. Dockerty, J. T. Priestley and M. W. Comfort. Surg. Gynec. & Obst. 104:746-750 (June) 1957 [Chicago].

It was accepted until quite recently that large ulcerating gastric lesions are malignant. In recent years there have been scattered reports on large gastric ulcers that were benign, but few of these have been proved histologically. The authors undertook a clinicopathological study of a relatively large group of such cases. The surgical files of the Mayo Clinic from 1940 through 1954 were examined for examples of chronic, benign gastric ulcer with a diameter of 4 cm. or more and for which gastric resection had been performed. Measurements had been made by the surgical pathologist at the time of the original examination of fresh tissue. During this 15-year period there were 100 cases that met the requirements. Data collected from the records and from gross and microscopic study of the surgical specimens form the basis of this report. The 100 cases of "giant ulcer" represented 4.1% of all cases of benign gastric ulcer treated surgically. The mean age of the patients was 53.2 years, the extremes being 3 months and 73 years. There were 78 males and 22 females. Ninety-three patients presented a symptom complex that was suggestive of peptic ulcer, namely, an intermittent, ulcer type of distress that occurred postprandially and that was relieved by ingestion of food or alkali.

The most frequent clinical diagnosis was that of carcinoma of the stomach, which was made in 45 patients. On the basis of roentgenologic findings, carcinoma was suspected in 40 patients and benign gastric ulcer was correctly diagnosed in 45 patients; various other benign conditions accounted for the remainder of the roentgenologic diagnoses. Gastroscopic examination did not appear to be of value in the diagnosis of large ulcers. The surgeon definitely stated prior to resection his opinion as to whether the lesion was benign or malignant in 24 patients. An erroneous diagnosis of carcinoma was made in 13 of these 24 patients. The Billroth 2 type of gastric resection was the procedure most frequently employed (in 76 patients). Of the 7 surgical deaths, 6 were due to generalized peritonitis; the 7th was due to bronchopneumonia. In 66 of the patients the ulcer had perforated or penetrated. The organ most frequently involved by perforation was the pancreas, the liver being next in frequency. The majority of the ulcers had circular outlines with sharp edges. Microscopic examination of the mucosa adjacent to the ulcer showed varying degrees of gastritis with associated hyperplasia of mucous glands, cystic glandular disorganization, and prominence of foci of lymphatic tissue in the base of the mucosa. The floor of the ulcer consisted of 4 rather indistinct zones; (1) a zone of purulent exudate, (2) a zone of fibrinoid necrosis, (3) a zone of granulation tissue, and (4) a zone of fibrous tissue. The authors conclude that a their typing paper. One girl solved the shorthand problem by wearing thin white cotton gloves. A draftsman started his day at the draftboard with a dozen handkerchiefs piled before him. It was necessary to wipe his hands before drawing every line to prevent smearing the ink.

Medical treatment was first tried on 9 of the early cases. It consisted of atropine by mouth, formaldehyde soaks for the hands, and small doses of x-ray therapy on the palms. These measures failed to produce satisfactory results. Twenty-one patients were subjected to surgical treatment, the 2nd and 3rd thoracic ganglions being removed in the first 4 patients. In the other 17 the ganglions were not removed but the chain was divided at the 3rd or 4th ganglion and sutured outside the thoracic cavity. One of the patients who had undergone ganglionectomy had a recurrence of the sweating 5 years later. Two others stated that their hands became moist in a warm room. The other 18 patients have had completely dry hands for from 1 to 15 years after the operation. The only treatment that offers the patient a complete cure is upper thoracic sympathectomy. Recent improvements in the surgical technique have eliminated the hazards of the operation and the morbidity and shortened the postoperative convalescence period to less than a week.

Cancer of Gastric Mucosa: Early Diagnosis. G. Martín Arribas. Rev. clín. españ. 65:31-36 (April 15) 1957 (In Spanish) [Madrid].

Early diagnosis of gastric cancer is possible when the cancerous lesion is located in the mucosa of the gastric wall or at a depth of not more than 2 mm. At this stage of the disease the patients complain of loss of appetite, fatigability, nervousness, moderate insomnia, and moderate loss of weight. The gastric symptoms consist of a dull gastric pain relieved by ingestion of food. Ingestion of food causes a sensation of gastric fullness which disappears on taking of sodium of bicarbonate. Occasionally the patients complain of severe tenderness on abdominal palpation. The diagnosis is established by roentgen examination, which demonstrates the cancerous lesion, no matter how small. Gastric cancer is classified into three stages: (1) lesions restricted to the parietal gastric mucosa, (2) lesions with lymphatic infiltration, and (3) lesions with hematogenous spread. Gastric cancer is curable in the early period by ample gastric resection. Three cases are reported. Two patients, 52 and 46 years old, respectively, presented themselves with gastric symptoms of 6 months' and 2 months' duration respectively. The roentgen picture of the lesion was minimal but definite. Gastric resection revealed the lesion to be the size of a pea. Histological study of the resected specimens revealed an adenocarcinoma in one and a papilloma with malignant degeneration of the mucosa in the other. The patients are in good health 1½ years and 6 months, respectively, after the operation. The third patient, a 74-year-old man, complained of symptoms of 2 years' duration. The roentgen picture show a cancerous lesion of the type of an encased ni There was lymph node involvement. Histolog study of the gastrectomized specimen showed that t line of resection passed just below the border of t lesion. The surgical treatment of cases of this ty should consist of a total gastrectomy with resection o the lower pole of the esophagus and a splenecto

The Surgical Treatment of Congenital Valvular Pu monary Stenosis Under Direct Vision During Hypothermia. E. Derra and F. Loogen. German M. Mont 2:129-132 (May) 1957 (In English) [Stuttgart, Germany].

Since the end of 1955, 9 male and 13 female pa tients between the ages of 5 and 44 years with co genital valvular pulmonary stenosis who had bee admitted to the surgical department of the Academ of Medicine in Düsseldorf, Germany, underwent su gery by direct vision on the open heart as describe by Swan in American literature, with the aid o hypothermia of about 30 C (86 F) according t Zindler's technique. The patient is placed in a rubbe suit through which water flows at a temperature o from —3 C (26 F) to +5 C (41 F), and in addition th patient is covered with a wet bath-towel with whic pieces of ice are wrapped up so that the meltin water runs directly down on the patients' skin. O the 22 patients with right ventricular pressures high than 70 mm. Hg, 10 had an isolated pulmona stenosis, 11 had a valvular pulmonary stenosis asso ciated with an atrial septal defect, and 1 had bo valvular pulmonary and infundibular stenosis asso ciated with a small ventricular septal defect. In patients the associated atrial septal defect was close during a second period of circulatory arrest, a fe minutes after the valvulotomy had been successful accomplished.

No significant complications occurred before after the operation, except in 2 patients. One died days postoperatively of a sudden massive hemorrha from a previously unsuspected duodenal ulcer. Th other died on the second postoperative day of multip small pulmonary emboli originating from clots on a endocarditic pulmonary valve. Comparison of pr operative and postoperative measurements of pu monary arterial and right ventricular pressures showe that results were very good in 6 patients with systolic right ventricular–pulmonary arterial pressu gradient of from zero to 10 mm. Hg, good in 7 with gradient of from 11 to 30 mm. Hg, and poor in 2 wit a gradient of more than 70 mm. Hg, although ther was an absolute drop in right ventricular and a ris in pulmonary arterial pressures after valvulotom The differences in the results are explained by th wide variation in the structure of the stenosed valv (the right ventricle was not opened, but the infundib ular portion was explored by finger from above). In some patients there was, in addition to the valvula enosis, a marked narrowing ("waist-like") at the se of the valve which prevented the reconstruction a normal outflow opening.

The advantage of the method used lies in allowing ie to perform an accurate and localized dilatation the valve without undesirable artifacts. Surgical mplications, such as have been reported by various rgeons using Brock's method of valvulotomy, are most unknown if hypothermia is skillfully conucted. The mortality was very low, and only 1 of the deaths could fairly be ascribed to the operation or the hypothermia. The operation can be performed patients of more advanced age than Brock's techque, as it was shown in a 44-year-old patient with ectrocardiographic evidence of myocardial damage ho tolerated the operation well. Surgical intervenon under direct vision also permits the repair of an ssociated atrial septal defect. Surgery by direct sion on the open heart is indicated in patients with ght ventricular systolic pressure at rest of more than 0 mm. Hg or in those with pressure between 70 d 100 mm. Hg in the presence of subjective comlaints or signs such as pronounced right ventricular ypertrophy revealed by the electrocardiogram.

ole and Interpretation of Arteriograms in Atherolerosis and Atherosclerotic Aneurysms. B. Eiseman nd H. U. Waggener. A. M. A. Arch. Surg. 74:934-943 une) 1957 [Chicago].

Radiologic visualization of the aorta or of the great essels of the lower extremities was performed in 134 atients, of whom 33 had atherosclerotic aneurysms nd 101 had obliterative disease. The obliterative rocess in 57 patients was at or distal to the bifurcaon of the common femoral artery. Thirty cubic centieters of 50% sodium acetrizoate (Urokon sodium) as used as contrast medium for abdominal aortogaphy and 20 cc. of 50% sodium acetrizoate for femoral rteriography. The diagnosis of atherosclerotic aneuysm can be made without its angiographic visualizaion, and such studies are now employed only when he indications for operation are in doubt or because f some other complicating factor. Comparison of the ngiographic profile of arterial aneurysms and their perative appearance in the 33 patients emphasized he limitations of the method in predicting the size of he aneurysm, the thickness of the organized thromus trapped beneath the concentric fibrotic peels of vhich the aneurysm is composed, and the consistency f the thrombus.

Any patient with obliterative arterial disease who. fter thorough clinical study, is a reasonable candidate or direct arterial surgery should have arteriographic isualization of the involved vessels. Such studies may urnish accurate data as to the level of arterial occlusion, the length of the occlusive process, its degree of encroachment on the lumen of the vessel, and the legree and location of collateral circulatory pathways and may indicate the condition of the vessels on both sides of the main occluding process. In an occasional case they will confirm or deny a diagnosis of obliterative disease that normally can be made on clinical grounds alone. The discrepancy between angiograms and the operative appearance of an atherosclerotic lesion, however, emphasizes that marked abnormal changes occur prior to their angiographic appearance and that both the length of the obliterative lesion and the degree of luminal involvement characteristically are underestimated by such studies. It is because of this discrepancy that surgical exploration of the distal artery is routinely performed as the first part of the direct surgical approach to atherosclerotic obliterative disease when its segmental nature is in doubt. Surgical exploration of the distal vessels (superficial femoral or popliteal artery) precluded further surgery in 12 of the 134 patients. In 5 other patients arteriography distal to the main point of obstruction showed evidence of such diffuse peripheral disease that further futile surgical interference was avoided.

Angiographic and operative changes similar to those observed in patients with atherosclerosis were found in the major vessels of the lower extremities in 4 of 8 patients with microscopically proved thromboangiitis obliterans (Buerger's disease). The unexpected angiographic finding of involvement of large vessels in patients with thromboangiitis obliterans complicates the differentiation of the latter disease from atherosclerosis, and the question arises whether thromboangiitis obliterans and atherosclerosis do not represent 2 variants of the same disease.

Problems in the Diagnosis and Treatment of Gas Gangrene. W. A. Altemeier. W. R. Culbertson, M. Vetto and W. Cole. A. M. A. Arch. Surg. 74:839-845 (June) 1957 [Chicago].

The authors report on 42 patients with clostridial myositis (gas gangrene). Clostridium welchii, the most important causative micro-organism, was present in all but 3 of the 42 patients, either alone or in combination with Cl. novyi, Cl. sporogenes and Cl. sordellii The interval between injury and the development of the lesion was variable, being as short as 6 hours in wounds associated with gross devitalization and contamination of muscle. The average incubation period was 53 hours. Pain was the earliest and most important symptom, being secondary to the rapid infiltration of the infected muscle by edema and gas. Rapidity and feebleness of the pulse usually followed the onset of pain and were characteristically out of all proportion to the elevation of the temperature. The average pulse rate at the time of diagnosis was 118, and the extremes were 100 and 160. Early, the blood pressure was normal or slightly elevated. Later, it became significantly lowered, falling precipitously in some patients to 40 mm. Hg or less. The temperature elevation in the early stages varied considerably between 97 F (36 C) and 107 F (41.8 C). Fever was not, therefore, a reliable index of the severity and extent of the infectious progress. A low or subnormal temperature associated with a markedly rapid pulse was indicative of a grave prognosis. A state of severe septic shock with anuria occurred in 5 patients. The usual malar flush associated with pyogenic infections was replaced by a peculiar grayish pallor. The mental state was often one of apathy and indifference. Stupor, delirium, and coma were late symptoms of an overwhelming infection. The early appearance of the local lesion, with the overlying skin either white, shiny, and tense or else essentially normal, was not that of a pyogenic inflammation. An irritating, dirty, brownish, watery discharge with a peculiar foul odor usually escaped from the wound. As the swelling increased, the overlying skin became dusky and bronze or khaki color in appearance. In far-advanced cases further discoloration occurred and vesicles filled with dark-red fluid appeared on the cutaneous surface. A marked reduction in the number of red blood cells or of the hematocrit or hemoglobin values occurred in many patients; the leukocyte count usually was not elevated above 12,000 to 15,000 per cubic millimeter. Roentgenograms taken at intervals of from 2 to 4 hours may aid in the differentiation of gas in the soft tissues produced by clostridial invasion from that due to mechanical or chemical causes. There are no satisfactory laboratory tests for the early diagnosis of gas gangrene. Any wound in which the presence of clostridial myositis is suspected should be explored surgically without delay. Radical operative treatment, as soon after diagnosis as possible, consists of multiple incisions and fasciotomy for decompression and drainage of the fascial compartments, excision of the involved muscles, or open amputation when necessary. The affected part must be adequately immobilized. Penicillin should be given intravenously in doses of 1 million units or more every 5 hours before and after surgical intervention. Tetracyclines, chlortetracycline or oxytetracycline preferably, should be administered intravenously in doses of 500 mg. every 4 to 6 hours. Polyvalent gas gangrene antitoxin should be administered before and after the operation, 50,000 units being given every 4 to 6 hours for 24 to 48 hours in patients with profound toxemia and hypotension. Secondary operative procedures to facilitate healing or to restore function of the wounded extremity should be delayed until the infection has been completely controlled.

NEUROLOGY & PSYCHIATRY

Subdural Haematoma in An Adult After Air Encephalography. R. G. Robinson. J. Neurol. Neurosurg. & Psychiat. 20:131-132 (May) 1957 [London].

The 48-year-old patient whose history is reported had fallen down some steps 18 months before and at that time had been unconscious for 4 hours. Two weeks later dull headaches at the back of the head began and persisted. There had been 4 attacks in this period when both his arms had been useless. On examination, he was depressed and somewhat agitated. The optic disk margins were blurred. He had a dubious weakness of the left arm. Radiographs of the skull were normal. On Feb. 14, a right carotid arteriogram was normal, and on Feb. 18 a lumbar encephalogram was done with 40 ml. of air. This was considered to be normal. On Feb. 26 the headaches were much worse, and he had a sudden short period of blindness. The next day he had poor upward gaze, slight left facial weakness, weakness of the left arm, and increased tendon jerks in the left arm and right leg; the right plantar response was extensor. On March 4 he was very drowsy, the left pupil was fixed and dilated, there was a left ptosis, and the left plantar response was extensor. A left carotid arteriogram showed that the left cerebral vessels were displaced to the left by a right-sided mass. On March 5, ventriculography was done by posterior bur holes under local anesthesia. The radiographs showed a large right sided mass. A right midparietal bur hole was made and a large subdural hematoma was evacuated. The brain expanded, but the patient died that night.

This patient died because it was not realized soon enough that he might have a subdural hematoma as a result of the encephalogram. Earlier treatment would have saved him. It was thought that he had a midbrain tumor which had escaped radiologic recognition. The physician whose patient deteriorates after encephalography is in a quandary. He is naturally reluctant to inflict further diagnostic procedures on his patient. The probability is that the patient had some untreatable condition. In rare cases the investigation has precipitated a subdural hematoma, and if there are any such doubts then the necessary bur holes should be made forthwith. It is possible that this complication is commoner than has been reported.

The Occurrence of Epileptic Fits in Leucotomized Patients Receiving Chlorpromazine Therapy. D. W Liddell and N. Retterstöl. J. Neurol. Neurosurg. & Psychiat. 20:105-107 (May) 1957 [London].

The authors used chlorpromazine in doses of from 100 to 600 mg. daily in 75 mentally disturbed patients. Twenty-one of these patients had previously undergone prefrontal leukotomy but still showed behavior disorders. Epileptic fits developed during chlorpromazine treatment in 7 of the previously leukotomized patients. These 7 patients had also previously received electroconvulsive therapy, but so had all of the other patients, who had not undergone leukotomy. The epilepsy of the 7 patients, one of whom died in status epilepticus, seemed closely related to the chlorpromazine medication. In 5 of the patients the fits occurred a few days after the treatment was started and in patient a few days after the treatment was discontinued. In 2 patients the fits were mainly unilateral. Five of the patients had not had epileptic fits after the operation, while the remaining 2 had had no fits for a period varying from 2½ to 4½ years. Electro ncephalographic investigations demonstrated that the sturbances arose frontally, and a focus of epileptic ctivity was found in one or other or both frontal bes. The authors suggest that when chlorpromazine given to patients who have undergone leukotomy, should be combined with antiepileptic treatment.

n Static Atactic Functional Disorders Caused by lcohol: A Comparative Study of Different Beverages. . A. Pihkanen. Quart. J. Stud. Alcohol 18:183-189 une) 1957 [New Haven, Conn.].

To study the static atactic swaying due to alcohol toxication the author carried out a series of experiments, applying the so-called modified Romberg test, ascertain the degree of static ataxia caused by two perimental beverages, namely, Finnish blended randy containing 32.6% alcohol by weight, and beer ntaining 3.6% alcohol by weight. The test dose in ch case was 1 Gm. of absolute alcohol per kilogram body weight, in the form of either blended Finnish randy or beer, divided into 6 equal, regularly spaced rinks taken on an empty stomach during the first 60 inutes of the experiment. Besides certain other tests, e quantative Romberg test was performed at the eginning of the experiment and again after 60, 120, d 240 minutes. The subjects were 12 men, all volunteers, varying in age from 22 to 43 years. All of them ere moderate users of alcohol. Compared with the redrinking value the increase of swaying in the men ho had taken blended brandy was statistically significant at 60, 120, and 180 minutes. In the beer series, n the other hand, the highest value at 120 minutes ould hardly be considered significantly different from e predrinking value. In the brandy series the maximum disturbance was produced earlier than in the eer series. Further, the maximum in the brandy series as more pronounced, showing (at 60 minutes) an crease in swaying of 131%, whereas the maximum t 120 minutes) of the beer series was only 37% higher an the predrinking value. Individual differences in action were considerable. The question of the correlation between blood alcohol and swaying requires rther investigation.

Meralgia Paresthetica. H. Stevens. A. M. A. Arch. Neurol. & Psychiat. 77:557-574 (June) 1957 [Chicago].

The symptoms of meralgia paresthetica are pain, numbness, itching, or other dysesthesias in the distribution of the lateral femoral cutaneous nerve of the thigh, that is, over the anterolateral aspect of the thigh, usually in an elliptical patch and usually unilateral. The perception of pinprick and touch is often diminished or lost. There is no motor disturbance; the lateral femoral cutaneous nerve is entirely sensory. The author reviews literature reports and reports observations on 42 patients with meralgia paresthetica, encountered over a period of 7 years. Only 16 were referred for neurological examination, primarily for sensory defects involving the thigh. In the other 26 the disease was discovered by inquiry into the presence of dysesthesia of the thigh and by direction of the sensory examination to this area. The patient with meralgia paresthetica may be seen first by the general practitioner, internist, orthopedist, obstetrician, or surgeon. Meralgia paresthetica is common, it occurs through a wide range of ages, and it is almost always benign and rarely due to sinister disease. However, a careful neurological and physical examination is required to rule out causes other than nonspecific neuritis, e. g., neoplastic or degenerative disease. The diagnosis of idiopathic meralgia paresthetica should be suspected (1) if the area of objective or subjective sensory defect exceeds the well-circumscribed area of distribution of the lateral femoral cutaneous nerve, (2) if other neurological signs or symptoms coexist, and (3) if there is a history of intra-abdominal disease. The last has been known to implicate the nerve, and this may be a manifestation of intra-abdominal or intrapelvic disease.

Many causes have been suggested for meralgia paresthetica in the literature, and the author believes that some deserve further comment, particularly those observations that suggest mechanical forces affecting the lateral femoral cutaneous nerve at or near the inguinal ligament or iliac crest. Dissection of the lateral femoral cutaneous nerve of the thigh in 47 cadavers revealed multiple variations, but none that would necessarily cause vulnerability to meralgia paresthetica. Treatment in the series of patients reviewed consisted exclusively of laissez-faire management. The benign nature of the mononeuritis was explained and the patient reassured. Contrary to the recommendation of many authors, surgery was not advised. Follow-up examinations of the patients with classic meralgia paresthetica justifies this position. The prognosis varied, but in most the dysesthesia persisted, being often intermittent and occasionally precipitated by standing, walking, or pregnancy. It was rarely distressing or disabling.

A Two-Year Comparative Study of Ataraxics in Neuropsychiatric Patients. V. M. Pennington. J. Am. Geriatrics Soc. 5:421-429 (April) 1957 [Baltimore].

Clinical trials of ataraxic drugs have been conducted on 2,360 neuropsychiatric patients including those with schizophrenia, manic-depressive psychosis, epilepsy, Huntington's chorea, meningoencephalitis syphilitica, and senile and arteriosclerotic psychoses. Of 350 patients, who had received 11,320 shock treatments in the course of a year, selected from among 451 patients whose disease was chronic, 20% (70) were allowed to go home, all save a very few returning to the hospital when the effect of shock therapy wore off. Six months treatment with reserpine enabled 42.8% (150) to return home, only 20% (30) returning to the hospital, most of whom had discontinued the medication. Even those patients remaining in the hospital were noted as improving in clarity of thought, coherence, orientation, rapport with associates, cleanliness, application to gainful occupation, interest in life, pride in self, responsiveness, and ability to live quietly and peacefully. It is remarkable that many of the patients who had spent from 10 to 30 years in the wards for the disturbed and had benefited only slightly from shock and other therapies were still at home 2 years later, still taking the prescribed dosage of reserpine. The side-effects of reserpine included pytalism, tremor, and muscular aches and pains, with 3 patients (0.3%) developing Parkinsonism. Dermatitis caused chlorpromazine therapy to be discontinued in many cases, but no Parkinsonism, agranulcytosis, or jaundice had occurred despite the relatively high dosage.

Meprobamate, an excellent somnifacient and the most popular ataraxic among the patients, was successful in many patients (82%) in that it dispelled delusions and hallucinations and reduced the tension and anxiety that predispose to noisy, assaultive, hyperkinetic behavior. Meprobamate relieved hyperhidrosis and mitigated the acrid odor of sudoral secretion. The whole root of Rauwolfia *serpentina* with side-effects similar to but markedly less than reserpine was successful in patients with senile and arteriosclerotic psychoses. Pipradol, a useful analeptic in conjunction with reserpine and meprobamate, cleared the thinking in arteriosclerotic and confused senile patients; its action, centered in the cortical and subcortical areas, stimulated interest and attention and alleviated depression. Methyl-phenidyl-acetate was effective in apathetic, negativistic, dull, inert individuals, stimulating them to activity and cleanliness. A double-blind study of 5 ataraxic drugs carried out in 196 patients showed the longest duration of beneficial effect with reserpine and the highest rate of improvement with chlorpromazine. Rauwolfia and chlorpromazine had side-effects which were labeled "annoying," while meprobamate and azacyclonol had no side-effects. All of these drugs induced varying degrees of reduction in blood pressure. Since the inauguration of this chemotherapy, no treatment other than supportive psychotherapy has been administered at this institution. All of the patients, including those on the so-called disturbed and violent wards, are quiet and orderly and wear clothing, temporary seclusion being necessary only occasionally.

Electrocardiographic Changes in Patients with Acute Carbon Monoxide Poisoning. A. Myschetzky. Ugesk. læger 119:615-618 (May 16) 1957 (In Danish) [Copenhagen].

Electrocardiographic examination of 67 patients with acute carbon monoxide intoxication revealed changes which were ascribed to the intoxication in 40 patients, of whom 9 were under 50, 10 were between 50 and 60, and 21 were over 60. Fifteen died. The most frequent changes, in the order of their frequency, were abnormalities in the T waves, sinus tachycardia, changes in the S-T segment, and auricular fibrillation or flutter. In some cases the changes disappeared.
19 of the patients with abnormal electrocardiogra
there were also electroencephalographic, clinical,
pathological signs of cerebral injury.

The Scope for Hypnosis in General Practice. A. Fr
Brit. M. J. 1:1323-1328 (June 1) 1957 [London].

Hypnosis in general practice is of necessity sim
and involves sessions of brief duration. Fixed gaz
and verbal suggestion were found to be the m
successful for the induction of hypnosis. The meth
utilized varied with the individual cases with the
ception that no drugs were used. Slight degrees
hypnosis (hypnoidal and light trance) were usua
sufficient but were generally replaced by deeper sta
in the treatment of obsessional and anxiety cases.
degree of hypnosis was unsuccessful, 14%; hypnoi
and light trance, 63%; medium trance, 9%; and d
trance, 14%. In those cases involving no deep-roo
causes or conflicts, light hypnotic state is sufficient
permit removal of the patient's symptoms by sug
tion. Deeper states are required in the treatment
neurotic and psychosomatic disorders, as relaps

treatment has failed to abrogate the causative fac
still partly submerged at the subconscious level.
largest group of patients treated were those
psychosomatic and psychoneurotic disorders, w
the most resistant cases included the obsessional
tients and adult asthmatics. Patients so treated
able to stop taking hypnotic, analgesic, and a
cholinergic drugs or drastically reduce their use,
several patients were able to stop smoking perman
ly. None of the patients exhibited any deterioratio
their original condition as a result of hypnothera

GYNECOLOGY & OBSTETRICS

Evaluation of the Prediabetic State During Pregna
E. R. Carrington, C. R. Shuman and H. S. Reard
Obst. & Gynec. 9:664-669 (June) 1957 [New York

The prediabetic state associated with pregnancy
been recognized of late as an important cause of f
wastage, which is higher in the unrecognized
diabetic than in the patient with well-contro
diabetes. The principal maternal abnormality is hy
glycemia (associated with insulin deficiency) result
from a defective carbohydrate tolerance. This s
may be aggravated by at least 2 hormonal alteratio
increased level of corticosteroids and possible incre
in growth hormone. Patients were selected who ga
history that included any one or more of the followi
(1) family history of diabetes; (2) history of intraute
fetal death; (3) delivery of infants exceeding 4,500 G
(10 lb.); (4) glycosuria during pregnancy; (5) hydra
nios; and (6) repeated abortions or premature labo
Glucose-tolerance tests were regarded as normal wh
the blood sugar level was 120 mg. per 100 cc. or l

in two hours. Fasting values greater than 120 mg. 100 cc. were found in overt diabetes. Patients were sified in 1 of 3 groups depending on the degree of iation from normal pregnancy values: group 1 picious), 120-140 mg. per 100 cc.; group 2 (pre- betic), 140-170 mg. per 100 cc.; group 3 (gestational betes) over 170 mg. per 100 cc. Indications for early very in those patients in whom abnormal curves e discovered in the prenatal period included a sistent abnormality in carbohydrate tolerance in nen whose histories revealed high fetal loss with vious pregnancies, the appearance of a toxemia ch was not readily reversed, or the development of lramnios.

n the authors' series, the fetal mortality rate was % when the prediabetes was discovered early in gnancy and 28.6% when it was discovered late or er delivery. The fetal mortality rate for these women previous pregnancies was 30%. Labor before term urred spontaneously or was induced in 50% of the nen whose prediabetes was diagnosed early.

dometrial Lavage as an Aid in the Diagnosis of rcinoma of the Endometrium. D. G. Morton, J. G. ore and N. Chang. West. J. Surg. 65:113-125 (May- ne) 1957 [Portland, Ore.].

Whereas cytologic study of the vaginal smear has wed of great value in detecting cancer of the cervix an early stage, the vaginal smear has not been very able in the detection of carcinoma of the endo- trium. The authors attempted to obtain representa- samples of material from the endometrial cavitary smearing and cytological study by injecting a small ntity of sterile saline solution into the uterine ity and aspirating the return flow from the posterior ginal fornix. After exposure of the cervix by means a bivalve speculum, an ordinary vaginal smear is de. Mucus and blood are wiped away, and after direction of the uterine cavity has been determined mall cannula is inserted just past the internal os. A inge containing sterile saline solution is attached to end of the cannula, and 3 to 4 cc. of solution is ected into the uterine cavity under low pressure. e cannula is withdrawn, and the fluid allowed to n back into the posterior vaginal fornix, from which is sucked up into the syringe again. It is then de- sited in a centrifuge tube and sent to the laboratory. mples of the centrifuged sediment are sucked up ith a micropipette and smeared on slides previously eated with egg albumin. The slides are fixed in the her-alcohol solution for 30 seconds. If the specimen bloody, the slides are removed and treated with 10 *N* hydrochloric acid solution for 1 minute and en returned to the fixative. The fixed slides are ained by Papanicolaou's technique.

Since the initiation of the project, 797 lavages have een obtained from 673 patients. The method accu- ately diagnosed cancer in the uterine cavity in 24 of 6 histologically proved cases. There were 11 false-suggestive or false-positive cases. In 655 instances both a lavage specimen and a vaginal smear were available for study. Endometrial cells were identified in 553 of the lavage specimens, or 84.4%, while such cells were found in only 52 of the vaginal smears, or 7.9%. These results indicated clearly the superiority of endometrial lavage as a sampling technique for endometrial cells and suggested that the probability of finding positive cells in cases of adenocarcinoma of the endometrium would be greatly enhanced. The authors conclude that this diagnostic technique could be of great assistance in the management of irregular and excessive menstruation and of intermenstrual spotting at or near the menopause.

Occult Carcinoma of Breast. A. F. Nogues. Obst. & ginec. latino-am. 15:117-121 (March-April) 1957 (In Spanish) [Buenos Aires].

Undetectable primary carcinoma of the breast is clinically recognized by the presence of a unilateral or bilateral axillary enlarged lymph node. The author reports 6 such cases in women between the ages of 41 and 70 years. The enlarged axillary node was noted by the patient 1 month to 2½ years prior to the consultation. It was apparently static or slowly growing. The breast was apparently normal, although slightly enlarged. In one patient there was a blood discharge from the nipple. A diagnosis of secondary cancer from inapparent cancer of the breast was made by histological study of the resected lymph node, by biopsy of the breast, or by examination of the bloody secretion from the nipple. A radical operation was performed in 5 cases. Histological examination of the removed specimen showed that the tumor of the breast was scirrhous in 2 patients, medullary in 1, comedocarcinoma in 1, and sarcoma in 1. This type of cancer is very malignant. The treatment consists of a radical mastectomy followed by postoperative, deep roentgentherapy.

The Hypophysectomy Program for Advanced Breast Cancer: A Preliminary Report. V. P. Hollander, G. Crutchfield and J. Martinez. Virginia M. Month. 84: 286-289 (June) 1957 [Richmond].

Approximately half of the patients with breast cancer have tumors that are sensitive to estrogen and should benefit by the removal of this growth stimulant. Oophorectomy removes the major source of estrogen in premenopausal women, whereas the adrenal cortex is a significant source of estrogen in postmenopausal patients or in those with a recurrence after castration. Hypophysectomy removes the source of the follicle-stimulating hormone and corticotropin, the hormones that stimulate the ovary and the adrenal to estrogen production. It is possible that some remissions after hypophysectomy are due to the removal of the growth hormone, prolactin, or some other pituitary factor. It is difficult to select patients for hypophysectomy. It might appear advisable to defer ablative surgery as long as possible and then perform adrenalectomy first, reserving hypophysectomy for those patients in whom adrenalectomy fails or in whom it is followed by relapse. Hypophysectomy can be done as the first palliative treatment for the generalized disease. Because endocrine ablative procedures have given higher remission rates than treatment with exogenous steroid hormones, the authors have reserved the latter for the treatment of relapses after ablative surgery.

All 9 patients reviewed in this paper had progressive metastatic disease. Three of them had not as yet reached the menopause, and castration had produced unsatisfactory results. Preoperative care in hypophysectomy is essentially the same as for bilateral adrenalectomy. The night before the operation the patient is given 6 intramuscular injections of 50 mg. of cortisone acetate at hourly intervals. On the morning of the operation 100 mg. of cortisone acetate is given by mouth. The hypophysectomy is carried out through a transfrontal approach. The histories of 2 women in whom the hypophysectomy achieved striking objective improvement are presented. Two of the 9 patients died after the operation; one patient failed to respond; 4 achieved striking remissions; and in 2 the pain was greatly relieved, but they will require further evaluation. The results obtained encouraged the authors to utilize hypophysectomy as a major palliative treatment for advanced breast cancer.

The Hazards of Intrauterine Pessaries: An Evaluation. R. W. Weilerstein. West. J. Surg. 65:157-160 (May-June) 1957 [Portland, Ore.].

The Federal Food and Drug Administration regulates interstate commerce in dangerous or misbranded devices. To assist in the evaluation of the status of the intrauterine pessary, questionnaires were sent to 187 diplomates of the American Board of Obstetrics and Gynecology. Their replies described not only the gold-plated and latex-covered pessaries but also glass, silver, aluminum, and hard rubber stem intracervical and ring intrauterine pessaries which they had found on surgery in uteri of patients made ill by their presence. Replies were received from 129 of the 187 gynecologists, of whom 101 were definitely opposed to the continued distribution of intracervical pessaries for any medical use; 18 were opposed to their use but felt that under certain qualifying circumstances they could be legitimately used; and 9 were favorable to their continued use but felt that some restriction as to their use should be observed. Only one physician stated unqualifiedly that he considered them to be safe and efficacious.

The replies indicated that 179 women suffered severe illness or injury due to intracervical or intrauterine contraceptive pessaries. The reported effects included infection and its complications, imbedding, irritation, perforation, migration, coincident ectopic pregnancies, and cervical carcinoma. In 2 of these the
pessary was imbedded in the cancer. The author b
lieves that the limited indications for the use of t
intracervical pessary in the surgical treatment
dysmenorrhea or anteflexion of the uterus can be r
by using other methods than the intracervical, in
uterine stem, or wishbone pessary, which is wid
sold for contraceptive purposes. The consensus
experts overwhelmingly condemns the continued d
tribution of intracervical and intrauterine pessaries f
any medical purpose.

**Hyperthyroidism and Pregnancy: Clinical and Stati
cal Observations on 46 Patients.** P. Battarino and
Capodacqua. Minerva ginec. 9:263-269 (April 15) 19
(In Italian) [Turin, Italy].

Forty-six pregnant women with hyperthyroidi
were admitted to a hospital in Bari during the peri
1925 to 1955. The same hospital received during t
same period a total of 45,057 pregnant women. Eig
een patients had exophthalmos, 14 a simple goiter
a cystic goiter, 7 other forms of hyperthyroidism, a
6 had been subjected to thyroidectomy some time
fore pregnancy. The average age of the patients
31.1 years. About one-fourth of the patients
primiparas. Seven patients, 4 with exophthalmos
with hyperthyroid goiter, and 1 with another form
hyperthyroidism, had a premature delivery. Gest
occurred in 7 patients with exophthalmos. Three
tients had cartiopathy, 2 patients had goiter, and 1
exophthalmos. Pregnancy had a bad effect on hyp
thyroidism in 11 patients and a good effect in 1 pati
Seven of the 11 patients had exophthalmos. The c
dition remained stationary in the remaining patie
Hyperemesis caused therapeutic interruption of
pregnancy in 2 patients. A total of 25 fetuses
delivered. Five of them died. Five patients ha
pathological puerperium. Thirty-six patients
subjected to medical treatment: 1 improved, 27
mained stationary, and 8 got worse. The thyroid sy
toms were checked in 4 patients that were subjec
to surgical treatment, but 3 of these patients
abortion. The remaining 6 patients had been subjec
to operation on the thyroid long before they beca
pregnant. Hypothyroidism was not present in th
patients during pregnancy. These 6 patients ha
total of 15 pregnancies, 10 of which were carried
normally; 1 was interrupted during the 7th month, a
4 aborted. Two of the 12 fetuses born alive from th
patients died.

Surgery Alone for Endometrial Carcinoma. E. Sandberg and C. E. McLennan. Obst. & Gynec. 670-675 (June) 1957 [New York].

While radiation (usually intrauterine radiu
coupled with surgery appears to be the favored met
od of treatment of endometrial carcinoma, there a
recent evidences that the advocates of preoperati
radiation are being seriously challenged. One hundr
thirty-three patients with endometrial carcino

ited over a 15-year period form the basis of this re- t. The standard procedure in the surgically treated up of 79 patients was total hysterectomy with iexal excision, including preliminary suture closure he cervix and tubes. Preoperative irradiation of the patients treated with both radium and surgery was cted variously by intrauterine tandem, Y-shaped, 5-portal triangular applicators. Twenty-five patients re treated by irradiation alone, receiving from 4,000 7,200 mg.-hr. of intrauterine radiation. The survival es (irrespective of the type of therapy) were 80.7% l 54.5% for the 5-year and 10-year follow-ups re- ctively. The large discrepancy between the 2 sur- al figures is attributed to death due to intercurrent ease between the 5th and 10th year. This discrep- cy is believed to be enhanced by the age-of-onset tor, for which no statistical compensating device is ilable. Radiation alone gave the poorest results, e to the inherent inability of intrauterine radium destroy cancer within the myometrium or adnexal uctures. Twenty patients whose clinical stage of ease was comparable to that of the women in the nically operable group were treated with radiation me, 55% surviving for 5 years. Of those women iose uteri were removed, 90% survived irrespective whether preoperative radiation was utilized. An un- ually high survival rate (95%) was noted where there is no gross extension of the tumor beyond the intra- lvic generative organs and where tumor in the erative specimen was confined microscopically to e uterus regardless of the depth of myometrial pene- ation. No attempt was made to correlate survival te with uterine size or with tumor differentiation. se of preoperative radiation seems wasteful from the andpoint of the patients' time and money and ap- ars to offer no improvement in prognosis, while sterectomy has been of such import that it is ad- dged the common denominator of successful therapy.

horiocarcinoma of the Uterus with Report of Two ases. E. S. Groseclose. Virginia M. Month. 84:296- 3 (June) 1957 [Richmond].

Choriocarcinoma has been known for years as horionephithelioma, but, because this term is mis- eading, it has been discarded in favor of choriocar- inoma. This highly malignant tumor arises as a nalignant change of the trophoblastic tissue and herefore may develop following a full-term preg- iancy, a miscarriage, an early abortion, or more fre- quently a hydatidiform mole. It is generally accepted hat about 40% of cases of choriocarcinoma develop after a hydatidiform mole, 35% after abortion, and 25% after a full-term pregnancy. Choriocarcinoma is so rare that many large clinics do not have even a single case on record. The author observed 2 women with this form of malignancy in the course of 5 years. Both of these patients died. The first patient, a 49-year-old woman with symptoms of menopause, had an extensive friable hemorrhagic tumor in the uterus with metastases in the sigmoid colon and in the lungs. Friedman's test was persistently negative. In the second patient, a 31-year-old woman, the choriocarcinoma arose 3 years after the expulsion of a hydatid mole. Pulmonary metastases were present, but death probably resulted from a cerebral hemorrhage 2 months after the operation.

Early diagnosis is vital in choriocarcinoma and is accomplished by means of tissue studies, x-ray examination, and hormone tests. The primary and the most frequent symptom of choriocarcinoma is bleeding, and any bleeding after miscarriage or pregnancy should cause suspicion of carcinoma. In some cases, the appearance of metastases in distant organs, especially the lungs, brain, vagina, or vulva, may be the first indication of a choriocarcinoma. This neoplasm most frequently appears as a somewhat circular, circumscribed raised or nodular mass of dark reddish hemorrhagic tissue of grumous consistency, involving some portion of the uterine wall. It may show surface ulceration or present as a smooth, slightly elevated surface. The tumor may also develop within the wall of the uterus (intramural variety) and may not be reached when curettement is done. It is in this variety that the diagnosis is so often missed. The lesion in the uterus may be comparatively small even in the patient who dies from extensive metastases. The primary uterine lesion sometimes undergoes complete regression, and death occurs from widespread metastases. Microscopically, choriocarcinoma is characterized by a disorderly growth of trophoblastic tissue, usually in alveolar fashion, invading the uterine muscle, with a gradual destruction of the myometrium and extensive coagulation necrosis and hemorrhage. The villous pattern usually is soon lost, though slight traces may remain. Both layers of the trophoblast, the Langhans and syncytial, are involved in the invasive process, but in varying degree. The accepted method of treatment is panhysterectomy followed by irradiation therapy. The mortality is high, approximately 70 to 80%. The prognosis is grave in all cases, especially in those with distant metastases.

OPHTHALMOLOGY

Angioid Streaks and General Arterial Disease. H. G. Scheie and T. F. Hogan. A. M. A. Arch. Ophth. 57: 855-868 (June) 1957 [Chicago].

Ten patients are presented to offer evidence of the close relationship between angioid streaks of the retina, pseudoxanthoma elasticum, and clinical signs of widespread vascular disease. All patients had angioid streaks of the retina. Macular degeneration was present in 8. Pseudoxanthoma elasticum was evident in 8 patients. One patient had advanced Paget's disease and another had signs suggestive of this disease. All patients had clinical evidence of arterial disease. Involvement was most marked in the lower extremities. The arteries of the upper extremities were involved in 6 patients. Pulses were diminished or absent. Arterial occlusion of varying degrees was present. X-rays revealed calcification in many of the medium and larger-sized arteries of the extremities. Intermittent claudication was a common complaint. Evidence of cardiac disease and myocardial damage was found in 3 patients. One patient had an aneurysm of the internal carotid artery and another had an aneurysm of each common carotid artery. Calcification was found in the walls of the aneurysms. A patient showed calcification of the choroid plexus of the brain and another calcification of the internal carotid artery. Bilateral calcification of the renal arteries as well as of the celiac axis was seen in another patient. No disturbance in metabolism was demonstrated. The mechanism underlying the degenerative process is obscure. A close relationship of the angioid streaks, pseudoxanthoma elasticum, and generalized arterial disease is emphasized. Physical examination should be carefully carried out on any patient with obscure arterial disease, especially if occlusive in nature. The arterial disease can dominate the clinical picture, or even occur alone, as can angioid streaks of the retina or pseudoxanthoma elasticum.

PEDIATRICS

Congenital Unilateral Multicystic Kidney Associated with Maternal Rubella. E. L. Lipton and L. J. Scordamaglia. J. Pediat. 50:730-733 (June) 1957 [St. Louis].

A congenital unilateral multicystic kidney was found during the first examination on the day of birth in a male infant who was delivered with the aid of low forceps. Surgery was performed on the 6th day of life. The right kidney, liver, pancreas, and other abdominal viscera were examined and considered normal. The operation and subsequent period were grossly uneventful. The infant was discharged on the 14th day of life in excellent condition. Subsequent outpatient examinations revealed normal growth and development. Whether the maternal rubella infection, diagnosed in the first trimester of pregnancy, was etiologically related to the pathology is not known; the association seems rather suggestive in view of the known adverse effects of this disease on the developing fetus. Congenital unilateral multicystic kidney is etiologically, therapeutically, and prognostically unrelated to congenital polycystic kidney disease. The mass may be extirpated if the contralateral kidney is normally functioning, and a normal life span can be assured.

Aminophylline Toxicity. H. Soifer. J. Pediat. 50:657-669 (June) 1957 [St. Louis].

Aminophylline toxicity occurred in 37 pediatric patients with respiratory ailments; 11 died. Aminophylline is a potentially toxic drug that may cause severe reactions or even death, due usually to overdosage or to hypersensitivity. Symptoms of toxicity caused by
aminophylline are chiefly restlessness and frequ
vomiting. More than 50% of the patients develop f
and convulsions. Albuminuria is an inconstant find
Irreversible damage and death occur if the drug is
withdrawn immediately. The rectal administratio
the drug in suppository form is recommended, s
aminophylline is not so effective when given or
appears to be most toxic when given intravenou
and is painful and irritating to the tissues when g
intramuscularly. In order to decrease the possib
of overdosage, aminophylline should be made a
able in 50-mg. and 100-mg. strengths. The simult
ous administration of aminophylline and ephed
appears to be contraindicated. A suggested dosag
aminophylline given rectally is 5 mg. per kilogra
body weight every 8 hours. The treatment of am
phylline poisoning is purely symptomatic; it inv
immediate withdrawal of the drug and the use o
propriate supportive measures.

**Patients with Infantile Primary Tuberculosis Tre
with Protected Cortisone Therapy.** A. Del Prin
E. Canova and R. Potenza. Lotta contro tuberc
80-89 (Jan.-Feb.) 1957 (In Italian) [Rome, Italy].

Fifteen children, 2 to 12 years old, 3 with ade
athy, 9 with various forms of tuberculosis, and 3
exudative pleurisy were treated with cortisone
bined with antibiotics. Each child received a do
0.5 mg. per kilogram of body weight per da
prednisolone combined with 20 mg. of strepto
and 10 mg. of isoniazid per kilogram per day. Pr
solone was administered for an average of 15 da
was discontinued after 7 days in 1 child and aft
days in 2 children. Suspension of cortisone the
caused the return of the symptoms present befor
treatment in 1 child. A second course of predniso
which lasted 15 days had a beneficial effect in
child. A first course of treatment did not have n
effect on 1 patient, but a second course given af
months had a marked beneficial effect. Antib
therapy was always continued after the suspensio
cortisone therapy. Best results were observed
after 2 or 3 days of treatment in the children
pleurisy, and good results were obtained in the
dren with adenopathy. The treatment had no ef
on one child with simple tracheobronchial adenopa
Improvement of the general condition of the pati
was obtained in a short time: the fever dropped
the body weight increased. Erythrosedimentation
became normal even before the suspension of
treatment. Glycemia and diuresis were always nor
All of the children treated are close to recovery.

**Congenital Afibrinogenemia: Report on a New-b
Infant Without Fibrinogen.** B. J. Grossman and R.
Carter. J. Pediat. 50:708-713 (June) 1957 [St. Lou

A report is made on a newborn infant with conge
tal afibrinogenemia because of the rarity of the dise
and the remarkable coagulation defects. The bab

ivery was described as a "very difficult midforceps." e mother's Kahn test was negative and her blood e was A, Rh positive. The infant was mature. newhat pale, and in acute distress. Examination led a diagnosis of congenital afibrinogenemia. Despite equate therapy the baby died at 13 hours of age. e 2 brothers of the baby have been reported as ving epistaxis but no other hemorrhagic manifestans. There is no history of bleeding in the father. A ect in the coagulation mechanism of the father and 2 brothers were observed. The increased clotting nes indicated a reduction in fibrinogen. Only 31 tients with apparent congenital absence of fibrino- n have been reported to date. The most striking and aracteristic findings in all patients is the incoagula- ity of the blood since birth. The hemorrhagic manitations are frequently less severe than those in mophilia. The hereditary pattern of congenital brinogenemia was given some attention. Cousin arriages have occurred in parents or grandparents 7 patients. Siblings with bleeding disorders were und in 7 other patients with congenital afibrino- nemia; hypofibrinogenemia was reported in 1 or ore relatives of 4 patients. The fibrinogen levels have en normal in other families of patients with congeni- l afibrinogenemia. The use of clotting techniques as sensitive means of detecting fibrinogen deficits is scussed.

ongenital Defects in Infants Following Mumps During Pregnancy: A Review of the Literature and a eport of Chorioretinitis Due to Fetal Infection. J. olowach, D. L. Thurston and B. Becker. J. Pediat. :689-694 (June) 1957 [St. Louis].

The relation of maternal mumps to fetal damage is ot as certain as that of the rubella infection in the other during the first months of pregnancy, which ay cause fetal death or congenital malformation. It s been shown that mumps complement-fixing anti- dies readily cross the placenta. Levels for such tibodies are essentially identical in the maternal and rd blood. A 6-month-old girl with congenital chori- etinitis is reported on, and the defect has been tributed to such an infection. Complement fixation d skin testing should be performed 2 months after irth in infants with congenital defects following ma- rnal mumps to establish this causal relationship.

ffect of Phenylalanine-Restricted Diet in Phenylketo- uria II. F. A. Horner, C. W. Streamer, D. E. Clader nd others. A. M. A. J. Dis. Child. 93:615-618 (June) 957 [Chicago].

Six children with phenylketonuria, 2 boys and 4 irls, between the ages of 6 weeks and 4¼ years, 3 of hom had been reported on in a previous paper, were eated with phenylalanine-restricted diets for periods arying from 8 to 22 months. The phenylalanine-free iet consisted of a protein hydrolysate basal mix (4.2 Gm. per kilogram a day), fat in the form of vegetable oil (3 Gm. per kilogram a day), and carbohydrates (10 Gm. per kilogram a day) for 3 weeks. After the initial 3-week period, phenylalanine, in the form of natural protein, was added to the diet in sufficient quantity to maintain the serum phenylalanine level between 3 and 5 mg. per 100 cc. (usually 3 to 8 Gm. of protein a day). Two children who were not placed on the phenylalanine-restricted diet until the 5th year of life showed sustained increments in their intellectual functioning. One of the 2 children treated in the 3rd year of life showed marked acceleration in her developmental pattern, while the other showed little significant change after 14 months of treatment. The remaining 2 patients were newborn infants who were treated since the appearance of phenylketonuria at the age of 6 weeks; they were following a healthy developmental pattern after 21 and 7 months of treatment respectively.

These observations tend to support the newer concept that the mental retardation pattern in phenylketonuria may not be so severe as initially described by Jervis. The treatment of older children with phenylketonuria may prove valuable in some patients in whom sustained improvement of mental function occurs. The treatment of newborn infants with phenylketonuria may prevent the characteristic and profound mental changes often associated with this abnormality. Urine examinations for phenylketonuria in the newborn period apparently may not give positive results before the age of 6 weeks, and negative urinary tests for phenylketonuria may, therefore, be misleading during the neonatal period.

Childhood Accidents and Their Prevention. H. Jacobziner. A. M. A. J. Dis. Child. 93:647-665 (June) 1957 [Chicago].

Three thousand nonfatal accidents in children under supervision in New York City Health Stations were reported between 1951 and 1955, and 1,151 accidental poisonings, fatal and nonfatal, were reported to the poison control center in New York City in 1955. Data regarding the natural history of these accidents, obtained by epidemiologic investigations carried out by the New York City Department of Health, suggest that falls and burns are the primary offenders in the accident group and acetylsalicylic acid (aspirin) and lead are the chief offenders in the accidental poisonings. The boy is more susceptible than the girl, and the nonwhite is more vulnerable than the white. The higher susceptibility in the nonwhite is believed to be a reflection of socioeconomic conditions such as overcrowding and poor housing rather than of inherent and constitutional differences. The kitchen is the most dangerous place and the bedroom is the next most hazardous place in the home. Lack of adult supervision is a deciding contributory factor. Accidents, which are responsible for more deaths in the preschool child than the 10 leading communicable diseases combined, follow an epidemiologic pattern like disease processes and are amenable to control measures. Attention must be focused on the most vulnerable groups with high attack rates and on injurious agents most commonly incriminated.

A careful analysis of each accident indicated that about 95% were preventable. The type of accident is intimately associated with the child's stage of growth and development. Accident proneness was not observed as a pattern. This observation does not confirm findings of other observers. Accident control is a medicosocial community-wide program which must be based on sound epidemiologic principles. Since accidents, like disease conditions, are due not to a single cause but to a variety of conditions and causes, a multidisciplinary approach is essential. Prevention is crucial, and education is the keystone of the program. Through daily contact with families and children, the physician is in a most strategic position to provide health education on safety during his regular visit in the home for the care of the sick. Considerable health education, guidance, and counselling can also be provided during office visits. The physician should also advise on the need for safe and well-supervised recreational activities in public playgrounds. As a leader in the community he can also motivate interested groups, such as parent-teacher associations, health councils, 4-H clubs, the Scouts, and other organizations, in initiating safety and accident prevention programs. Further epidemiologic investigative research is needed, particularly about the emotional and human factors and the psychodynamics involved.

Steroid Therapy in the Nephrotic Syndrome. S. Dundon. J. Irish M. A. 40:135-144 (May) 1957 [Dublin].

Eight children, 6 boys and 2 girls between the ages of 3 and 11 years, with the nephrotic syndrome including proteinuria, hypoproteinemia, edema, and hypercholesteremia were treated with corticotropin (ACTH) given in daily doses of from 80 to 120 mg. for 10 days combined with antibiotic therapy (20 mg. of tetracycline per pound of body weight daily). The effect of the hormone on the proteinuria was good in all patients. Five of the 8 patients became clinically well, with normal blood chemistry and normal composition of urine, for periods of from 3 months to 3 years. Rapid clearing of the protein from the urine was observed. One boy relapsed after such clearing, and clearing recurred in the course of treatment with a daily dose of 5 mg. of prednisolone for 1 week. One of the girls with a 2-year history of edema and proteinuria who had been confined to bed showed striking clinical improvement. She again was able to carry on a normal life and was free from edema for one year; although she still was losing 1 Gm. of protein in the urine, her protein loss was diminishing. The other girl had received 2 10-day courses of corticotropin, and, although she responded regularly with diuresis and loss of edema, her plasma protein level remained low,
the albumin fraction always particularly so. Althc
she was still losing about 1.5 Gm. of protein in
urine per day she remained edema-free and her bl
protein level improved on continuous treatment
prednisolone in daily doses of 25 mg. combined
tetracycline therapy.

The effect of both corticotropin and predniso
thus has been most gratifying in these patients.
sponse to therapy would appear to depend to
extent on adequate dosage over at least 6 days.
biotic therapy is of great importance in the man
ment of patients with the nephrotic syndrome;
any sign of infection such therapy should be imm
ately initiated and, when treatment with steroic
instituted, it is essential that antibiotic therapy
given at the same time. The importance of full
with no added salt is stressed.

National Policies for the Prevention of Rickets
Lightwood and T. Stapleton. Ann. paediat. 188:27
(May) 1957 (In English) [Basel, Switzerland].

This paper describes experiences in Britain ir
virtual eradication of rickets. The most importa
the changes in the nutrition of children in the U
Kingdom now, compared with 1915, that explain
disappearance of rickets is the improvement in
general standard of nutrition together with a
appreciation by the government and the people o
value of regular administration of vitamin D in
early years of life. The second major change i
provision of cod liver oil supplements and vita
fortified dried milks by the maternity and child
fare clinics. Thirdly, vitamin tablets and a sp
allowance of milk are made available to preg
women. One danger has become apparent, na
chronic hypervitaminosis D. In this connection
authors point out that in the preparation of
milks an excess of vitamin D was being adde
some manufacturers in order to ensure that
powder contained not less than its stated conte
vitamin D. This extra vitamin D "coverage" was n
because there is some loss of vitamin D activity
ing storage.

The methods of prophylaxis used in Britain are
directly applicable to other countries; understan
of local conditions is necessary. The general n
tional standard will be influenced by economic co
tions and the receptiveness of the public and
authorities to education about diet. A simple wa
many countries to provide vitamin D would be
exposing the infants to sunshine. Yet in many part
the world where there is adequate sunshine
mothers keep their children in the dark indoors
the first 2 years of life. In these circumstances
mothers must be told that sunshine in suitable amo
is beneficial. The provision of a daily supplement
vitamin D first to the pregnant woman and then to
child is desirable. Here, however, one runs into d
culties of distribution and of ensuring that there i

ular intake. Recently the authors heard of a little l who came into an outpatient clinic wearing a autiful yellow bead necklace made of UNICEF amin A and D capsules. Foods can be fortified, but s must not be overdone. Provision must be made vitamin supplements to children who are entirely east fed. Treatment of rickets with a single massive se is not recommended.

bstructive Emphysema in Infants: 40 Cases. T. Vallor, L. Borbolla and C. Satanowsky. Rev. cubana diat. 29:173-194 (April) 1957 (In Spanish) [Havana].

Obstructive emphysema of the bronchial tree is fre- ent in newborn infants and in infants up to the age 6 months. The symptoms and course of the disease ry with the type and location of emphysema and e occurrence of complications. The disease starts th a respiratory disorder and cough with or without ver. Forty patients were observed in a period of 5 ars in a pediatric clinic of Havana. Most of the pa- nts were newborn infants and infants under the age 3 months. The clinical features of the disease were e sudden appearance of asphyxia in almost all of e cases, associated with dyspnea, cough, and cya- osis ,and diminished movement of the chest. The usal factor was aspiration of food or of amniotic id in 2 cases, allergy in 1, viral infection in 25, and cterial infection in 11. Emphysema was diffuse in cases (bilateral in 16 and unilateral in 6), lobar in , and bullous in 2. Segmental atelectasis occurred in patients, mediastinal emphysema in 3, pneumo- orax in 3, and cardiac insufficiency in 18. The treat- ent consisted of postural drainage, oxygen adminis- ation, nebulization with detergent substances, and ministration of antibiotics and, in cases of cardiac sufficiency, digitalis. Recovery took place within 2 ays in 20 patients and within 5 days in 17. Three wborn infants died, 1 from mediastinal emphysema d 2 from lobar pneumonia. The authors advise early stural drainage to prevent dissemination of obstruc- on into the bronchioles. Postural drainage is obtained placing the patient in the lateral position and rais- g the foot-board of the cradle 15 or 20 degrees with spect to the head board.

xperiences with Therapy for Anemia of Prematurity. Pototschnig and A. Verga. Minerva pediat. 9:242-50 (March 3) 1957 (In Italian) [Turin, Italy].

Anemia is one of the most threatening complications premature infants because of its high incidence and everity and because of its influence on the organic esistance to infectious diseases. Two stages of anemia f prematurity must be distinguished: early and late. he transition from early to late anemia takes place radually and is frequently not perceived. The peak f early anemia occurs between the 7th and 10th week f life. Early anemia is normochromic or slightly hypo- hromic, macrocytic, and associated with reticulocyto- is. Late anemia is evident in the second 6 months of life and culminates at the end of the first year of life. It is characterized by hypochromia and microcytosis combined with anisopoikilocytosis. Early anemia has been more completely studied than the late. Its severity depends on various factors, such as the different degree of organic and functional maturity, the weight of the premature infant at birth, and the influence of aggravating factors, such as infection, dystrophy, or deficiency of vitamins.

Various pharmacological therapies and blood transfusions were employed by the authors in the treatment of premature infants with and without anemia, and the results were compared. Blood transfusion alone prevented the occurrence of early anemia in premature infants. Starting with the 5th month a constant increase of erythrocytes was observed, but the hemoglobin level decreased progressively. Prolonged treatment with iron appeared to prevent late anemia of prematurity. The oral administration of iron simplified the treatment, which can thus be prolonged indefinitely. The best results in treating anemia of prematurity were obtained when both prophylactic therapies were combined.

Reticuloendotheliosis (Non-lipid) in Infants and Children. H. N. Sanford. Illinois M. J. 111:297-302 (June) 1957 [Chicago].

This report is concerned with granulomatous, or nonlipid, reticuloendotheliosis. The pathological process involved is thought to be a disturbance of the intrinsic metabolism involving the cells of the retculoendothelial system. This process differs from the lipid form as seen in Gaucher's disease and Niemann-Pick disease in that there is a tendency for the formation of discrete granulomatous lesions rather than a diffuse infiltration. Lipid accumulations either do not occur or, when they do develop consist of cholesterol and cholesterol esters. Among the 2,859 children under 12 years of age admitted over a 5-year period to Research and Educational Hospitals there were 11 with nonlipid reticuloendotheliosis. In 5 of these children the disease began during the first year of life, and these had the so-called Letterer-Siwe type of disorder. A rash, enlargement of liver and spleen, and generalized lymphadenopathy were present in all of these 5 children. There was also a history of repeated respiratory infections, and the entire course was characterized by repeated infections. Three had roentgenographic evidence of pulmonary infiltrations, and 2 showed rarefied areas in the bones of the skull. All 5 infants had a hypoplastic type of anemia, and the course in all of them was steadily downhill. The average life span was between 5 and 18 months. Only 1 of these 5 children is still surviving.

Five other children, in whom the disorder began at 2 or 3 years of age, had the Hand-Schüller-Christian type of disease (histiocytosis of cholesterol type). While all of these children had some loss of weight, anorexia, and other complaints, none were acutely ill. Only 2 had an initial rash, and in 1 a rash developed later but was never diffuse. Two had hepatic and splenic enlargement, but all had generalized lymphadenopathy. All exhibited roentgenographic lesions of skull or bones. Biopsy showed foam cells filled with cholesterol droplets surrounded by a zone of fibrosis, after the disease had existed for a year. All of these 5 children are living. Only 1 child, an 8-year-old boy, had eosinophilic granuloma, a solitary lesion of the radius. There was no enlargement of liver and spleen or adenopathy. Microscopic examination of material from the granuloma showed granulomatous eosinophils and large mononuclear cells, containing no lipid material. The boy has been well for the past 2 years and has shown no other lesions.

This series of 11 cases indicates that all 3 types of *reticuloendotheliosis* are part of the same disorder. The difference is only in the degree or intensity of the disease, which is linked to the age of the child. Treatment was unsuccessful in the younger age group, although the infants were made more comfortable and their life span was increased by adrenocorticosteroids, corticotropins, antifolic acid compounds, transfusions, and antibiotics. The older age group responded well to the above treatments plus pituitary compounds to control polydypsia and polyuria.

UROLOGY

Influence of Urinary Glucuronide on Solubility of Calcium Phosphate and Stone Formation: Experimental Urolithiasis XII. C. W. Vermeulen, B. Finlayson and W. Chapman. J. Urol. 77:685-696 (May) 1957 [Baltimore].

Neuberg and Grauer, using menthol glucuronide as the test material, reported that the presence of glucuronides increases the solubility of calcium phosphate. Using this finding, Prien and Walker suggested that salicylate administration may be beneficial in patients with urolithiasis since salicylate is excreted in part as conjugated glucuronides. Experiments were done to see if confirmation of this concept could be obtained. In the first experiment, foreign bodies were placed in the bladder's of rats to stimulate stone formation. Feeding of aspirin failed to inhibit stone growth, but it was found that rats do not excrete significant amounts of administered salicylate as conjugated glucuronides. Therefore, isoborneol, a known augmenter of glucuronide excretion, was tried. Again, stone formation was not inhibited. In the second experiment, the original observations of Neuberg and Grauer on the solubilizing effect of menthol glucuronide were extended to include concentrations at more physiological levels. While their original observation with high concentrations could be confirmed, the solubilizing power of this was barely detectable
at glucuronide concentrations comparable to
that could be expected from salicylate administ
In the third experiment, salicylamide was int
tently administered to 2 normal human subjects
urine was studied for calcium phosphate solubil
2 different methods. No difference was found be
the urines obtained during treatment and tho
tained in the *intervals between* treatment.

**Acute Hemorrhagic Cystitis: An Infection Asso
with Pleuropneumonia-like Organisms and Rela
Urethritis and Prostatitis.** R. L. Berg, H. Wein
and L. Dienes. Am. J. Med. 22:848-864 (June
[New York].

Of 88 Navy patients, men with an average
22.3 years, with unexplained genitourinary infe
usually *unresponsive to sulfonamides* and per
57 (65%) had positive cultures from the uri
pleuropneumonia-like organisms (PPLO). Ele
these 57 patients had cystoscopic evidence o
abacterial pyuria, characterized by pyuria, hem
frequency and urgency, fever, suprapubic and p
pain, and severe hemorrhagic inflammation
bladder with membranous sloughs, for which t
acute hemorrhagic cystitis is preferred by t
thors. Of a second group of 9 men with genito
infection and with positive cultures for PPLO,

Two of the 15 patients with cystoscopic evid
acute hemorrhagic cystitis had arthritis, 3 ha
junctivitis, and 1 had epididymitis. Occasionall
was hydronephrosis subsequent to the intense
of ureteral orifices, and it was accompanied by
vertebral angle tenderness. A follicular rash
served in 1 patient. The prostate was characteri
enlarged, firm, or nodular and tender in 8 p

It is suggested that PPLO are the infective
of this disorder in view of their presence i
cultures, the absence of other bacterial organ
which the condition could be contributed, and
appearance of PPLO during successful treatme
arsenicals, streptomycin, and the tetracyclines.
control persons, 51 hospitalized Navy patients
senting complaints referable to the genitourina
and 47 men in the process of being separated fr
naval service, 36 had positive cultures for PPL
the urine, an incidence of 36.7%. If only thos
entirely negative genitourinary findings amo
control persons were considered, 17% had
cultures for PPLO from the urine. In additio
probable role in the causation of acute hemo
cystitis, PPLO possibly are responsible for many
of nongonococcic urethritis and prostatitis. It is
that the organisms are transmitted venereally
they are thus present with much greater freque
promiscuous males, and that after an initial inf
they may linger asymptomatically in the uret
prostate.

THERAPEUTICS

icylate Intoxication Treated with Intermittent Posi- Pressure Respiration. S. Freier, B. W. Neal, H. I. Nisbet and others. Brit. M. J. 1:1333-1335 (June 1) 7 [London].

lany cases of salicylate intoxication are the result accidental ingestion of the drug. Heymann states t the danger of intoxication is much greater after rapeutic administration of the drug. Holt has shown t the dosage of salicylate administered does not r a constant relationship to the blood level and t the blood level at which toxic symptoms appear ies greatly. One of the many common and most portant symptoms of salicylism is hyperventilation, ich is due to reflex stimulation of the central re- ratory mechanism via afferent fibers of the vagus ve. Hyperventilation is responsible for the state of alosis which ensues and which is clinically mani- ted as tetany. Due to the fact that electrolytic dis- bances are secondary to hyperpnea, therapy is ected toward reduction of the respiratory exchange d hyperactivity of the respiratory musculature. Ex- rimental studies have indicated the limitations re- rding hyperpnea and the secondary biochemical anges using barbiturates and opiates. Use of these ugs was abandoned when they were found to cause longed coma and death due to sensitization of the imals to these drugs by salicylates. In the case cited, perpnea of salicylate poisoning was successfully ated by neuromuscular block (5 mg. of suxameth- ium at 5-minute intervals for 15 minutes) and nually controlled intermittent positive pressure piration. The response of the patient to carbon xide inhalation precludes its use in treatment of s type disorder. Calcium gluconate administered relieve tetany was ineffectual, as the tetanic condi- n was not related to calcium ion blood levels.

able Tubercle in Closed Lesions. J. V. Hurford and . H. Valentine. Tubercle 38:194-198 (June) 1957 ondon].

Tubercle bacilli present in "closed" necrotic lesions n be grown only with great difficulty. Though visible direct films, the bacilli often appear nonviable. ecimens for study were restricted to those patients ith radiologically "minimal" or very limited disease, ithout cavitation, who had a history of tuberculosis 6 months' duration but must not have had a positive utum on smear or culture during the 6-month period ior to resection. The laboratory procedure was es- ntially that of Holly and co-workers. In this series, patients (80%) had a positive smear in one or more mples, the smear being positive in 64 instances 8%). No correlation was demonstrated as regards ability and the number of visible bacilli and none between the number of visible bacilli and the amount of growth on the culture. A relationship would seem to exist between the size of closed lesions (foci) and the number of tubercle bacilli on culture and/or guinea pig inoculation. The duration of chemotherapy has little or no effect on the number of tubercle bacilli seen on direct examination or the frequency of occurrence of atypical bacilli. Only 2 of all of the positive cultures showed definite drug resistance. The persistance of closed lesions is not usually attributable to their insensitivity to chemotherapeutic agents.

A Clinical Study of Anticoagulants in Acute Myocardial Infarction with Particular Reference to Early Heparin Theory. G. L. Eastman, E. T. Cook, E. T. Shinn and others. Am. J. M. Sc. 233:647-653 (June) 1957 [Philadelphia].

The use of anticoagulant drugs in the management of patients with acute myocardial infarction is still an unsettled question. Three hundred sixty-two patients were admitted to the University Hospital and divided into 3 groups: (1) untreated, (2) treated with Dicumarol, and (3) treated with Dicumarol and heparin. The mortality rate was higher in the untreated cases and least in the group treated with Dicumarol, the differences being relatively insignificant unless the early (24-hour) deaths are counted. There was a lower incidence of thromboembolic phenomena in anticoagulant-treated patients; however, hemorrhagic phenomena were greater here than in untreated patients, especially in the heparin-dicumarol group. Superficial examination of statiscal data suggests that anticoagulants are of value, but consideration of the severity-of-illness factor implies differences in death rates. Early use of heparin seems of little value considering the increase in hemorrhage and lack of significant alterations in either mortality or incidence of thromboembolism.

Application of Homeostatic Principles to the Management of Nephrotic Patients. N. B. Talbot, J. D. Crawford and C. D. Cook. New England J. Med. 256:1080-1084 (June 6) 1957 [Boston].

Observations on nephrotic children indicate that sodium retention and edema are not necessarily the result of an intrinsic loss of renal capacity to excrete sodium salts and water. Metabolic studies concerned with edema in children with the nephrotic syndrome point to a series of reactions and to the primary pathological loss of albumin in the urine. This series of reactions in order of occurrence consists of (1) fibrinoid degeneration of glomerular basement membrane, (2) albuminuria, (3) hypoalbuminemia, (4) hypovolemia, (5) renal sodium conservation, (6) increased body solute stores (e. g., sodium), (7) renal water conservation, and (8) increased extracellular volume (e. g., edema, ascites). A number of factors employed in the management of nephrotic edema are utilized at various points in the progressive reaction scheme to prevent or reduce the edema. Corticosteroid therapy is indicated at the initial fibrinoid degenerative stage, as corticosteroids are singularly effective in reducing albuminuria due to the destruction of the basement membrane. This type of therapy is unique in that corticosteroids alone tend to suppress the degenerative process primarily responsible for the course of the disorder. Albumin infusion and blood transfusions are relatively effective at the hypoalbuminemic and hypovolemic stages respectively. Attempts to induce a sodium diuresis at the renal sodium conservation level by mercurial diuretics and other similar agents is relatively ineffective and possibly causes some renal damage. Restriction of water intake and paracentesis are of little value save for some small relief afforded the patient.

Aplastic Anemia Due to Chloramphenicol. N. O. Madsen. Ugesk. læger 119:489-491 (April 18) 1957 (In Danish) [Copenhagen].

The author has considered chloramphenicol the most effective antibiotic in the treatment of chronic lung infections. Where even large doses of penicillin (500,000 to 1 million units twice daily), possibly combined with streptomycin, were without effect and tetracyclines also were unavailing, chloramphenicol led to prompt fall of temperature and rapid decrease in expectoration. The risk in the treatment has been considered slight, especially in view of the frequently grave character of the basic disease, and not essentially different from that in treatment with other antibiotics. A fatal case of aplastic anemia after repeated long-continued treatment with chloramphenicol occurred in a woman aged 59 with mitral stenosis and chronic bronchitis. The danger of aplastic anemia from chloramphenicol is negligible on careful dosage during an acute infection, but there is increasing risk in massive, prolonged, or repeated treatment.

PATHOLOGY

Persistence of Intra-atrial Septum in the Aged: Physiopathological and Anatomicochemical Studies of Cases. F. Barboni. Sett. med. 44:591-599 (Dec. 15) 1956 [Florence, Italy].

The cases of two women, 72 and 56 years old, who died of congenital heart defects are reported. The patients reached the age of 67 and 56 respective- ly without cardiac complaints. The first patient suffered repeated episodes of heart decompensation with marked dyspnea and cyanosis for 5 years before death. Clinical examination revealed enlarge- ment of the heart and accentuation of the second pulmonary sound. Enlargement of the median arch and of the branches of the pulmonary artery, which appeared pulsating, were observed on roentgenolog- ic examination. Persistence of the fossa ovalis with marked hypertrophy and dilation of the right left cardiac chambers were observed at autopsy. T right auricle contained large thrombi. Fibrous diff gray lesions were seen in the myocardium. At sclerosis was present in the pulmonary circulat especially in the large extraparenchymal branches the pulmonary artery and in the large and med arteries. Large scars, evidence of latent ischemic farcts, were present in the spleen and in the kid The second patient had asthma, dyspnea, and ed in the lower limbs for some years before her de Free effusion in the left pleural cavity and in t abdomen, enlargement of the heart, and an acc tuated second pulmonary sound were noticed on ical examination. Autopsy showed a congenital de of the heart with a persistence of the foramen o due to incomplete development of the septum, hy trophy, and dilation of the heart. Severe diffuse at sclerosis was observed in the vessels of the cardium and several foci of myocardial scl Severe atherosclerosis was present in the pulm circulation.

Incidence of Hepatitis Following Transfusi Whole Blood. R. Katz, H. Ducci, H. Benne J. Rodríguez. Am. J. Clin. Path 27:406-421 (Apr [Baltimore].

An attempt was made to determine the incide of post-transfusion hepatitis in 193 recipients of wh blood transfusions and to correlate the findings in donors at the time of the donation with the incide of post-transfusion hepatitis in the recipients. Of t 193 recipients, 144 were followed up for periods from 5 to 12 months after having received wh blood. The clinical and laboratory features of hep titis were observed in 6 (4.16%) of the 144 patients the 6 patients, 2 men and 4 women, between the a of 19 and 62 years, 3 had received 1 transfusion, 1 received 2 transfusions, and 2 had received 7 tr fusions in the course of operations for repair of dominal wall, removal of pituitary adenoma, drain of pelvic abscess, removal of gastric carcinoma, ruptured ectopic pregnancy. The time interval tween the transfusion (or transfusions) and the servation of jaundice corresponded with the accep incubation period of inoculation hepatitis in 5 pati The short interval of 14 and 8 days, respecti between the first and second transfusion and the o of the first symptoms of jaundice in the 6th pa might have indicated the artificial transmissio natural hepatitis. The incidence of post-transf hepatitis was higher among those who received tiple transfusions (5.6%) than among those wh ceived only 1 transfusion (3.3%).

There was a lack of correlation between the re of liver function tests in the donor and the dev ment of hepatitis in the recipient. The 3 donors w blood induced inoculation hepatitis in the 3 reci who had received 1 transfusion had a normal le bilirubin in the serum and negative results fro flocculation tests at the time of donation. Conversely, hepatitis with jaundice did not occur during the time of observation of any of the recipients of blood from 33 donors who had abnormal levels of serum bilirubin, positive results from flocculation tests, or both. The only effective means of reducing the incidence of post-transfusion hepatitis is to give transfusions of blood only if they are specifically required.

Aneurysm of the Coronary Arteries. A. E. Gilbert, P. A. Snedecor and E. J. Losli. Northwest Med. 56: 699-702 (June) 1957 [Seattle].

One case of coronary artery aneurysm was found in 2,090 consecutive autopsies during a 10-year period. At the present time, 61 cases have been recorded in the literature and are classified as follows: congenital, 18; arteriosclerotic, 14; mycotic-embolic, 13; syphilitic, 7; due to polyarteritis, 2; mycotic, 1; rheumatic, 1; and unclassified, 5. This case represents the 14th of the arteriosclerotic type and the 3rd in which death was due to rupture of an associated arteriosclerotic aneurysm of the abdominal aorta. Destruction and distortion of the elastic lamina of vessel wall by arteriosclerotic plaques is considered one mechanism by which coronary artery aneurysms develop in arteriosclerosis.

An Experimental Study of Fat Embolism. N. A. Halasz and J. P. Marasco. Surgery 41:921-929 (June) 1957 [St. Louis].

Numerous thorough studies have been made of clinical and pathological changes occurring in simulated fat embolism with supposedly bland substances other than fat. This experiment utilized omental and perinephric fat from freshly killed dogs, macerated in a Waring blendor, filtered through multiple layers of gauze, heated and centrifuged, and injected with 5 cc. of isotonic citrate solution through a polythene cannula into the jugular vein. The immediate results obtained upon injection were apnea, bradycardia, cyanosis, systemic hypotension, and pulmonary hypertension. The persistent pulmonary hypertension immediately after injection is attributed to local vasoconstriction and arterial spasm. The animals showed an improvement minutes later, except for those animals who, having received larger doses, regressed, becoming cyanotic, exhibiting tachycardia and ultimately ventricular fibrillation, respiring irregularly, and dying in respiratory arrest. The resulting pulmonary hypertension involves other respiratory and cardiovascular changes previously described and called the Jarisch-Bezold reflex, consisting of systemic hypotension, bradycardia, and apnea. Due to the fact that embolization of the greater circulation occurs terminally in all animals, the question arises whether this is incidental to or the cause of the agonal collapse of circulation. The reestablishment of normal pulmonary circulatory dynamics, followed by passage of fat into the greater circulation, embolization of the brain producing cardiac arrest and death, and the lat appearance of fat in the left side of heart is postulated as a protective function of the lung preventing massive immediate peripheral embolization. The mechanism of death cannot be stated with absolute certainty, although anoxia is a significant factor. In this experiment no attempt was made to overcome respiratory arrest, and this condition always preceded cardiac standstill.

Splenic Forms of Hepatolenticular Degeneration. G. Boudin, B. Pepin and E. Fournier. Presse méd. 65: 952-955 (May 22) 1957 (In French) [Paris].

Disorders of proteins and copper metabolism appear in the first stage of hepatolenticular degeneration. In rare cases of this disease abdominal symptoms predominate. Splenomegaly, hypersplenism, purpura, and hemorrhage may be observed. These features lead in 67% of the cases to a diagnosis of Banti's disease and to splenectomy. The abdominal form of the disease can be so severe that death may occur in the hepatic stage, before any other form manifests itself. In most patients, however, the splenic form changes, at least partially, and the conventional nervous form appears, thus revealing the correct diagnosis. Hepatolenticular degeneration is a hereditary disease. Consequently, before resorting to a splenectomy in a child or a young adult, one should look for a family history of hepatic disease. It is important to search for a Kayser-Fleischer ring by slit-lamp examination, for hypercupremia, and for a hyperaminoacidemia, as all these factors help to establish the diagnosis. Splenectomy is a drastic operation in these frail patients. It does not remove the secondary neurological signs, which lead to death in less than 2 years. Latent hepatic disorders, discovered through biological tests or punch biopsy, are usually too far advanced for operative therapy.

RADIOLOGY

Radiographic Demonstration of Choledochal Cyst by Oral Cholecystography. J. E. Moseley. Radiology 68:849-851 (June) 1957 [Syracuse, N. Y.].

Choledochal cyst or idiopathic dilatation of the common bile duct is a congenital localized dilatation, the etiology of which is obscure. Choledochal cysts have been demonstrated directly by the introduction of contrast substances into the cyst through a needle puncture and indirectly by pressure defects on the duodenum and displacements of the adjacent structures. A review of the literature suggests that these cysts cannot be shown by oral cholecystography. In the 5-year-old girl whose history is presented, both the gallbladder and the cystic dilatation of the c mmon bile duct were demonstrated by oral ch
graphy with iopanoic acid (Telepaque). Th
of choledochal cyst was confirmed on
tion, and a cystoduodenostomy
hor ascribes the demonst

gallbladder in this case to the use of Telepaque and the fact that the patient was examined after her jaundice had cleared. He emphasizes the importance of preoperative diagnosis in reducing mortality from surgery in this condition.

A Survey of Complications of Abdominal Aortography. J. G. McAffe. Radiology 68:825-838 (June) 1957 [Syracuse, N. Y.]

A questionnaire was sent to 450 hospital radiologists and urologists in order to obtain information on the frequency of complications associated with abdominal aortography. Ninety-five of the 301 replies received stated that no abdominal aortograms had been performed. Of the 13,207 abdominal aortograms reported [illegible] the questionnaires, 12,832 were obtained by the lumbar needle technique and only 375 by the guide femoral catheter technique. A total of 37 deaths and 98 serious complications were reported, that is, the complication rate was 1.02% and the mortality rate 0.28%. Renal damage from the contrast medium was the most important complication, usually resulting from excessive injections, direct renal artery injections, or injections in patients with high aortic obstruction. The danger of neurological damage appeared to be increased by the use of spinal or general anesthesia, by excessive injections of the medium, and by the proximity of the needle tip to the major anterior radicular artery, usually at the level of the second lumbar segment. Hemorrhage from the puncture site was one of the less frequent complications. Although many hematomas were reported in the survey, in only 13 instances were these accomplished by shock and therefore considered to be serious complications; 5 of these were fatal. The hematomas were usually retroperitoneal, but sometimes were perirenal, peritoneal, or superficial. Thirteen serious cardiovascular reactions were encountered, with 5 fatalities. Several occurred in elderly, poor-risk patients. Ten gastrointestinal complications of various types were reported, 5 of which were fatal.

Less frequent complications included retroperitoneal sepsis, dissecting aneurysm, respiratory complications, complications at the site of insertion of the catheter, and extension of arterial thrombi. Although complications associated with aortography will probably never be entirely eliminated, the author cites some measures that might reduce their frequency. To guard against direct injection into the renal arteries or other aortic branches, a test film should be made routinely after the injection of only 5 cc. of the medium with the needle in place. The aortic needle should be inserted at a high level, well above the L-2 level. If examination of the kidneys or upper aorta is not required, insertion should be well below the level of the renal arteries. This also enables better visualization of the femoral and other peripheral arteries. Local anesthesia is indicated in most patients to minimize the danger of neurological damage. Abdominal compression or the 2-needle aortogram technique should be avoided. Excessive amounts of contrast medium (over 30 cc.) should not be used, and as few injections should be made as possible, particularly when the kidneys are exposed to the medium. Rapid serial films enable complete renal studies with a single injection. The newer contrast mediums may be safer than either acetrizoate (Urokon) or iodopyracet (Diodrast). In patients with high aortic obstruction, satisfactory studies may be obtained with no more than 12 to 15 cc. of medium, and usually a single injection suffices. Direct puncture of an aortic aneurysm must be guarded against because of the danger of hemorrhage. A 20-minute pyelogram should be obtained routinely to detect retroperitoneal bleeding; hypertensive patients should be closely observed for this complication. The effectiveness of preliminary injections of antihistamines or cortisone in preventing serious systemic reactions to contrast mediums has not yet been established. Severe reactions, however, have responded dramatically to intravenous preparations of cortisone.

Coproliths. R. M. Berg and H. M. Berg. Radiology 68:839-844 (June) 1957 [Syracuse, N. Y.].

The estimated incidence of coproliths ranges from 1 in 2,000 appendectomies to 1 in 10. The radiologist should be "coprolith-conscious." Whereas not a single coprolith was observed by the authors before 1949, they have been seen in 42 patients since. In 35 they were discovered preoperatively and in the others after the operation because the surgeon requested an x-ray study of the removed appendix. The most widely accepted explanation of the mechanism of coprolith development is that of Kelly and Hurdon (1905). It suggests that impairment of the normal peristaltic return of fecal content from the appendix results in inspissation. Subsequent irritation and bacterial activity cause a low-grade inflammation with mucus secretion. The inorganic salts, mainly calcium phosphate, contained in the mucus are precipitated on the surface of the fecal nucleus. Wangensteen and Bowers suggested that the appendix frequently behaves as a closed loop, permitting entry but preventing free extrusion of the fecal stream. They regard the closed loop phenomenon as the initiating factor in appendicitis and inflammation and suppuration as consequences of the obstruction. This explains why a patient may have a coprolith for some time before the development of acute appendicitis.

Reviewing observations on the 35 patients in whom the coprolith was recognized preoperatively, the authors emphasize the somewhat lower ages of their patients compared with those in other reports; all but 5 were less than 30 years of age, and 16 were less than 10 years old. The correct diagnosis can frequently be achieved only by x-ray examination of the abdomen. A calcified shadow or shadows in the right lower quadrant should immediately suggest the possibility of a coprolith, although a number of conditions such as bone islands, ureteral and vesical calculi, calcified mesenteric lymph nodes, phleboliths, calcified epiploic appendices, and ovarian and uterine calcifications may simulate coproliths. In the presence of a coprolith in a patient with acute abdominal symptoms, there is at least a 90% chance that the patient has an acute appendicitis and a 48% chance that the appendix is gangrenous or perforated. A survey of the literature reveals that most authors recommend an immediate appendectomy whenever a coprolith is found. The findings in this series are in agreement so far as the younger patients are concerned. Operation would not appear to be necessary in the symptom-free older patients.

Superficial Malignant Lesions of Bladder Treated by Radioactive Colloidal Gold (^{198}AU). P. I. Tuovinen and K. Kettunen. Brit. M. J. 1:1090-1095 (May 11) 1957 [London].

Intracavitary irradiation has a distinct advantage over externally applied roentgen rays in the treatment of multiple superficial lesions of the bladder. Several techniques have been developed for substances emitting gamma rays, but for very superficial lesions it seemed advisable to use beta radiation. Radioactive colloidal gold (Au^{198}) seemed suitable because of its short half-life (2.7 days), its type of emission, and its colloidal nature. It emits about 95% beta radiation and 5% gamma radiation. This preliminary report is based on experience with Au^{198} in the treatment of superficial lesions of the bladder. The patients treated included some with papillary cancers and some with recurring extensive papillomas without histological evidence of cancer.

The histories of 3 patients are described. Fluid intake was restricted on the day prior to treatment and forbidden on the day of treatment. When the activity in milicuries per milliliter had been determined, the desired dose in millicuries was drawn into the lead-shielded syringe and introduced into the bladder through an ordinary bladder catheter. Injection was readily accomplished after removal of urine by catheter. Sterile isotonic sodium chloride solution was used for rinses. The radiation dose in most cases ranged between 4,000 and 5,000 r, estimated at the mucosal surface. The doses were given as single exposures for 4 to 6 hours. The treatment had no harmful side-effects locally or on the general condition of the patient. Three selected cases suitable for Au^{198} therapy are briefly reported. The authors had the impression that this is an excellent type of irradiation for really superficial malignant lesions.

ANESTHESIA

Elective Cardiac Arrest During Cardiotomy: Summary of 37 Cases. D. E. Hale, P. P. Moraca and C. E. Wasmuth. Anesthesiology 18:378-388 (May-June) 1957 [Philadelphia].

Elective cardiac arrest with potassium citrate was used during open-heart operations in 37 patients. The duration of the arrest varied from 7 to 40 minutes, with an average of 17 minutes. After the patient's blood had been heparinized and his circulation had been assumed by the heart-lung machine, a clamp was placed on the root of the aorta. Immediately proximal to that clamp, a solution of potassium citrate in heparinized blood was injected into the lumen of the aorta just above the orifices of the coronary arteries. The amount of potassium citrate injected to produce temporary standstill of the heart was about 1 cc. per kilogram of body weight. Light anesthesia with thiopental sodium given rectally to children and intravenously to adults allowed rapid recovery, lessened the danger of nausea and emesis, and permitted a better evaluation of the general condition of the patient. For premedication meperidine hydrochloride and pentobarbital sodium were used. In the first 10 patients, the blood flow from the heart-lung machine was 35 cc. per kilogram per minute. Later, flows up to 70 cc. in children and 40 to 50 cc. per kilogram per minute in adults were used. Physiological changes that occurred during the procedure included a drop in body temperature, a rise in the serum hemoglobin level, a fall in the blood platelet count, and the appearance of acidosis. Metabolic acidosis was controlled to some extent by the respiratory alkalosis which accompanied the use of hyperventilation.

Of the 37 patients operated on, 18 had interventricular defects, 9 had tetralogy of Fallot, 3 had transposition of great vessels, and the remaining 7 patients had interauricular septal defects, pulmonary stenosis, and aortic stenosis. Thirteen of the 37 patients died. There were 4 nonpreventable surgical deaths. Three patients died of pulmonary complications. Six patients were considered to be surgical failures in that the defect was not adequately corrected. The postoperative period seemed to be more critical than the period of operation, and careful observation and supervision were required. Respiratory exchange, body temperature, and blood pressure must be kept within normal limits.

PUBLIC HEALTH

Clinical and Epidemiologic Research on Adenovirus (APC) in Italy. F. Curcio, G. Rolli, P. Filippi and D. Balducci. Sc. med. ital. 5:433-445 (Jan.-March) 1957 (In English) [Rome].

Twelve strains of adenovirus (APC) were isolated from the tonsils and the adenoids of 50 children. One specimen belonged to type 1, 6 to type 2, and 5 to type 5. Eleven specimens were collected on the day of operation and 1 15 to 20 days after operation. Neutralizing antibodies at a titer greater than 1:28 were found in all specimens. Negative results were obtained in isolation trials from 19 specimens of secretions from patients with respiratory syndromes.

Complement-fixation tests were carried out at the virology center in Rome during the last 6 months on 520 serums taken from patients in hospital wards of the city and from patients at an Air Force base where during the month of March some cases of pharyngoconjunctival fever were observed. Twelve positive and 4 probable specimens with adenovirus infections were observed. A marked increase of antibodies was found in the 12 patients with positive specimens. A titer 1:32 was observed in the 4 patients with probable specimens. Four patients came from the same area in the city of Rome. One patient had an exudative pericarditis and 2 a mediastinal pleurisy in addition to the lesion in the respiratory tract. It was not possible to discover whether these additional complications had been caused by the virus.

Simultaneous Mantoux and Vollmer Patch Tests in 5 School Children. V. C. Waegele, W. J. Rothrock R. *Van Scoyoc. Dis. Chest 31:634-642* (June) 1957 icago].

A comparative study of the results of the intracutaneous tuberculin (Mantoux) test with 0.1 cc. of a solution containing 0.00025 mg. of purified protein derivative, or 12.5 tuberculin units, and of the patch (Vollmer) test, the strength of which is equivalent to 2.5 tuberculin units, was carried out in 2 junior high schools in which the students were between the ages of 11 and 14 years. It was felt that the patch test might have advantages in the ease of administration and in acceptability to the students and their parents. The study was made to determine whether the patch test could be substituted for the intracutaneous test. The 2 tests were given simultaneously and the patch test had the disadvantage that in about 10% of the tests the patch became detached before the proper time interval had lapsed.

Of 855 students so tested, 83 reacted to both tests, 113 reacted to the intracutaneous test but not to the patch test, and 3 reacted to the patch test but not to the intracutaneous test. In general it was noted that in patients whose intracutaneous reaction was markedly positive the reaction to the patch test was also usually positive, but in those whose intracutaneous reaction was less marked, the patch test did not cause a reaction. When the result of the patch test was positive, the intracutaneous test almost certainly confirmed tuberculin sensitivity. One hundred thirteen persons had positive reactions of minimal readings (1 + or 2 +) to the intracutaneous test, and this group of persons holds special significance. If the persons in this group had been given only the patch test, 94 would have gone unrecognized as being sensitive. In a clinical situation dealing with individual contact patients in whom higher tuberculin doses could be used in repeat testing to rule out false-negative results, the patch test is satisfactory. There is not, however, convincing proof that a high proportion of clinicians routinely give persons with a negative reaction to the patch test an intradermal test of higher tuberculin strength to exclude the possibility of a false-negative reaction. The group of persons with a positive reaction to the intracutaneous test with minimal readings, moreover, is apt to be productive of active cases. The testing situation described in this paper is comparable with the previous screening in Los Angeles schools in which 20 active cases with previous intracutaneous minimal readings (1 + and 2 +) were determined out of 45 active cases with previous readings of all degrees.

Any failure to detect active cases far less pronounced than is indicated above would invalidate the use of the patch test despite its greater economy as to expense and work load. Intracutaneous tuberculin testing, therefore, should remain the method of choice in Los Angeles City schools. It is acknowledged that in other testing situations the patch test may be a useful procedure.

The Field Hamster (Cricetus cricetus) as Source of Infection with Swamp or Field Fever. H. Mochmann. Ztschr. Hyg. 143:327-333 (No. 4) 1957 (In German) [Berlin].

It was demonstrated in 1942 that the field mouse (Microtus arvalis) may harbor Leptospira grippotyphosa, the cause of swamp fever or field fever, and the author observed in the fall of 1955 field fever in one of a group of boys who during play had thrown field mice at one another; in so doing the boy in whom the fever developed had become contaminated with mouse urine. Serologic tests on this boy demonstrated that he had L. grippotyphosa infection. Studies during an epidemic fever among agricultural workers in pea fields in 1949 revealed another animal host of this organism, namely, the field hamster (Cricetus cricetus). When in 1955 the author observed an extensive epidemic of swamp fever in a region in which field hamsters are prevalent, studies were made to ascertain whether the hamsters harbored leptospirae. The kidneys of 2 hamsters yielded leptospirae. Five other hamsters, which had been trapped in the epidemic region and after that had been kept in the laboratory for several months, gave negative serologic tests. No leptospirae were found in the renal pulp of one hamster infected with a L. grippotyphosa strain from a mouse that had likewise been trapped in the epidemic region, but the serum of this hamster had a positive titer for L. grippotyphosa of 1:1,600.

While the field hamster subsists largely on vegetarian foods, he is known to prey on smaller animals, especially field mice and their young, and it is possible that in this way the animal became infected with L. grippotyphosa. That this organism is transmitted to man by hamsters is explained by the fact that these animals are hunted and killed by the thousands; in one region 13,970 had been killed in 1939, and a report of 1888 mentions the trapping of 97,519. Professional hamster trappers sell the pelts; furthermore, the animals are eaten, their kidneys being regarded as a delicacy. This may be another source of infection with field fever. The author also mentions that the golden hamster (Cricetus auratus) is susceptible to leptospiral infection: This animal has been used for experimental studies on L. canicola.

BOOK REVIEWS

Practical Otolaryngology. By Gervais Ward McAuliffe, .D., F.A.C.S., F.I.C.S., Associate Clinical Professor of tolaryngology, Cornell University Medical College, New ork. Cloth. $7. Pp. 320, with 13 illustrations. Landsberger edical Books, Inc., distributed by Blakiston Division, Mc-raw-Hill Book Company, Inc., 330 W. 42nd St., New York 6, 1957.

The intent of this book is to serve as a source of eference for the general practitioner for common ar, nose, and throat conditions. It is difficult for ny author to decide what to include and what to xclude in this type of work and for this type of udience. Unfortunately, there is an uninhibited endency among many specialists addressing themelves to nonspecialists to "write down" to this group, somehow assuming that oversimplification s a desirable diet. Actually, it is much more diffiult to write for nonspecialists than for one's specialistic peers. Viewed from this vantage, the book s unevenly organized and disappointing, especially since the author is known for his distinguished experimental studies on pain and headache in association with the nasal and paranasal structures. Oddly enough, he deals most inadequately with so common a subject as headaches and devotes only two terse paragraphs to external otitis, a disease that can hardly be classified as uncommon. "Bibliographies are carefully avoided" declares the author in the preface, yet a number of bibliographies appear at the end of several chapters. Despite some obvious shortcomings, the book illustrates personal experiences in otolaryngology that command attention. It is hoped that the next edition will approach the problems of the general practitioner on a higher intellectual level and will include more detail.

Hospital Treatment of Alcoholism: A Comparative, Experimental Study. By Robert S. Wallerstein, M.D., in collaboration with John W. Chotlos, Ph.D., and others. With introduction by Karl A. Menninger, M.D., Chief of Staff, Menninger Foundation, Topeka, Kan. Menninger Clinic monograph series no. 11. Cloth. $5. Pp. 212. Basic Books, Inc., 59 Fourth Ave., New York 3, 1957.

This book represents the findings of a two and a half year research project at the Veteran's Administration Hospital at Topeka, Kan. The purpose of the study was to compare different methods of prolonged treatment of alcoholic patients in a hospital setting. Four methods, disulfiram therapy, conditioned reflex therapy, group hypnotherapy, and closed ward therapy are described. The last group served as a control and differed from the others in that no special drug or technique was employed. The usual psychotherapy was used in this group. Hospitalization of each patient ranged from 60 to 90 days. One hundred seventy-eight hospitalized alcoholic male patients were studied with a follow-up period of two years. Patients were assigned to the various modalities on a random basis in the order of their admission. Exceptions were made when the physical condition of the patient would not warrant possible strain from disulfiram or conditioned reflex drugs. The data sought were those relating to alterations in the level of function. Measures of change were judged by degree of abstinence, social adjustments, subjective feelings of difference, and structural changes and personality configuration.

This study is a review of an exceptionally detailed research program. It covers the four modalities of therapy mentioned and gives details of the results accomplished. The types of patient in each group are described and categorized, and the effects of each of the modalities on the various classifications are tabulated. There are excellent tables, charts, reference lists, and indexes. Since the authors start with the premise that there there is no primary alcoholism but that alcoholism is symptomatic of some underlying psychiatric condition, it is understandable that the criteria of improvement may be at odds with opinions of others in the field. Whereas total abstinence is mandated by many as being the criterion of improvement, these authors consider moderation in drinking a definite sign of improvement in the patient's condition. The title of the book may prove to be somewhat misleading to the average physician, since it is only in rare instances that a patient is hospitalized 60 to 90 days for the treatment of alcoholism. For research purposes, a lengthy stay is advantageous, but many believe that hospitalization beyond the attainment of sobriety, or perhaps a few days longer, is of little value in helping the patient to a social adjustment.

This book should be of special value to physicians who are interested in research and comparative values of therapy. It could hardly be considered of practical value to the average doctor whose alcoholic patients can afford but a few days of hospitalization and whose therapy must be carried on in the atmosphere of the physician's office. For the physician especially interested in alcoholism, however, it presents an extremely valuable discussion of the four modalities used. The references are especially good and unusually complete. The introduction to the book, although not optimistic, is realistic in its approach and sets the stage for an objective and valuable study.

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

Clinical Proctology. By J. Peerman Nesselrod, B.S., M.S., M.Sc., Assistant Professor of Surgery, Northwestern University Medical School, Chicago. Second edition. Cloth. $7. Pp. 296, with 72 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1957.

In this new edition of an eminently useful and widely read book, originally entitled "Proctology in General Practice" and first published in 1950, fortunately, there has been little alteration of the text. The book was written especially for the general practitioner and leaves little to be desired. In this edition some new illustrations have been added; several which appeared in the first edition have been replaced, some in color. The short chapter on anal contracture is new and is of distinct value. The author is uncommonly apt at expressing himself concisely, yet adequately, and he thereby provides in this book a source of ready reference for the busy practitioner. When confusion exists as to terminology or classification, the author provides interpretations and arrangements that clarify his discussions. Surgical techniques are presented clearly and in detail. Well-chosen illustrations enhance the value of these descriptions. The chapter on anal infection deserves special attention, and the diagram of anal infection on page 70, a contribution which is original with the author, provides in a few words what is unquestionably the most lucid and accurate description, thus far, of the causes, sources, and mechanics of inflammatory disorders of the rectal outlet. Probably the most important phase of proctology is diagnosis. Thus, it is to the author's credit that he has prepared his chapter on diagnostic procedures in great detail. By so doing, he has provided valuable information that can be used not only by the general practitioner but by medical students, internists, and surgeons. In addition, the surgeon will find valuable information in the author's discussion of the surgical management of common anorectal inflammatory diseases. This is a thoroughly good book, and it can be recommended without qualification.

Therapeutic Exercise for Body Alignment and Function. By Marian Williams, Ph.D., Assistant Professor of Physical Therapy, Department of Allied Medical Sciences, School of Medicine, Stanford University, San Francisco, and Catherine Worthingham, Ph.D., Director of Professional Education, National Foundation for Infantile Paralysis, Inc. Paper. $3.50. Pp. 127, with exercise illustrations by Harold Black. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1957.

The authors of this book are physical therapists. The book is designed primarily as a working guide for therapists who desire to provide exercises for patients having various malalignments of the musculoskeletal system. It is profusely illustrated with line drawings, depicting various exercises. The book is divided into five chapters dealing with standing posture; analysis of body alignment, the therape exercise program, principles of treatment and ercises for the various areas, and positions of body in activity and rest. There is also an exten appendix containing illustrations demonstrating muscles of primary concern in alignment of the b and a discussion of the origin, insertion, and fu tion of these muscles. The manual is designed the use of all persons dealing with problems of b alignment and function. An effort has been mad select those corrective procedures that are best su ed for clinical application and to discuss them i terms of basic functional anatomy. The book, therefore, is concerned with selection and analysis o material rather than with the introduction of ne techniques. This manual is well organized wi clear type and good illustrations. Suitable bibliographies are appended to each chapter. The chapte on positions of the body gives many excellent illu trations of proper and improper ways of performin various activities. Although this book contains nothing new, it can be recommended as a well-orga ized teaching manual for student therapists and a a workbook for persons who are instructing patien in therapeutic exercises.

Atlas of Clinical Endocrinology Including Text of Diagnosis and Treatment. By H. Lisser, A.B., M.D., and Robert F. Escamilla, A.B., M.D., Clinical Professor of Medicin University of California School of Medicine, San Francisc Cloth. $18.75. Pp. 476, with 148 illustrations. C. V. Mosb Company, 3207 Washington Blvd., St. Louis 3, 1957.

This volume brings together, pictorially an graphically, the wide experiences of one of th world's pioneer endocrinologists and his associat It covers the clinical disorders of the pituitary thyroid, parathyroids, adrenals, gonads, and pancreatic islets. Most of the endocrinopathies presen certain physical characteristics that are in themselves diagnostic. This is evidenced in this atlas b 800 illustrations of various types of endocrine disorders. These illustrations are documented photographs of the authors' patients, many showing th patient before the onset of the disease, during subsequent stages of development, and after the result of successful therapy. Although the emphasis is o the illustrative material, the textbook, which i brief and concise though fully adequate, covers th symptoms, physical signs, essential laboratory procedures, differential diagnosis, and therapeutic schedules of each entity. It also provides valuabl reference material. An important feature of this book, one which has been neglected in most such books, is the section on nonendocrine disorders simulating or confused with those of endocrine origin—the so-called pseudoendocrinopathies. This book aims to provide the simplest and most direct avenue for learning and understanding clinical endocrinology for the medical student, general practitioner, and the specialist.

QUERIES AND MINOR NOTES

IDS AND ALLERGY

: Editor:—*For the past few months some 15 ren, their ages ranging from 18 months to 13 , have been treated for severe asthma and rhi- The older ones were malnourished, gaining only .2 lb. a year. They had no desire to play; their l grades were only fair. Physical examinations ed muscles to be soft and flabby, mucous mem- s of the mouth, nose, and throat were pale, and natic rales were always present. For the older ren 2.5 mg. of Meticorten was prescribed every ing and evening for a period of 10 days to two s; then, the rest of the month was skipped, after h the course was repeated. After this pro- re the dosage was changed to 2.5 mg. on the ing and evening of every third day. The re- se was excellent. These patients gained from 5 lb. a month; their activity increased, and they ed as normal children with no apparent fatigue; became jovial, whereas before they had been ned to be irritable, and their schoolwork showed arked improvement. The 18-month-old patient a severe allergic rhinitis, for which 1.25 mg. of icorten was given in the afternoon for two s; she received immediate relief. What effect do l doses of Meticorten produce on the adrenal d, and for what period of time could this dosage ontinued without any ill-effects on the patient? e much progress was noted from the small doses, here any relationship between allergy, the ad- l gland, and some type of cortisone used in ll doses?*

Arnold M. Smythe, M.D., Des Moines, Iowa.

WER—Side-effects have been observed after ged administration of Meticorten to allergic in- ials, these, however, have been less marked than cortisone is used. Ordinarily side-effects do not before approximately two weeks of continuous y. The usually accepted maintenance adult dose to 20 mg taken daily for weeks or months may, ition to the usual side-effects of prolonged steroid istration, result in "stress reactions" on with- al Shock or evidence of acute adrenal insuffi- y may develop when the patient experiences a condition, such as a severe infection, injury, surgical procedure, and administration of anes- c For this reason a Thorn test might be wise on mplation of Meticorten withdrawal after prolonged administration. This will indicate the state of adrenal cortical responsiveness. If the test is not practical, repository corticotropin (ACTH) may be administered for its adrenal cortical stimulating effect at the time Meticorten is withdrawn.

In the relatively small doses administered to the patients mentioned, there would be little likelihood of either the usual side-effects or the significant adrenal suppression, and, under proper medical supervision, the drug might be administered in the prescribed dosage for several weeks or months in interrupted courses if it were deemed necessary. It is extremely important, however, that concurrent or intercurrent bacterial infections be adequately treated with a suitable antibiotic, and, in the presence of a specific virus disease, the steroid should be used with extreme caution. After exposure to or in the presence of chickenpox, the drug should be discontinued and gamma globulin administered in adequate doses.

Cortisone, hydrocortisone, Meticorten, and similar steroids have no specific relationship to the allergic state. Apparently they act as a buffer to the disease toxin or irritant, decrease inflammatory exudation in some instances, but do not affect the antigen-antibody reaction or the formation of histamine.

REPEATED CONGENITAL MALFORMATIONS

To the Editor:—*An anencephalic monster was recently delivered of a woman whose first baby, born in September, 1953, was also an anencephalic. She had a normal child in April, 1954, and another normal child in February, 1955. How often have two such abnormalities been present in any one family? What are the statistics on the likelihood of abnormality again appearing if sterilization is not done?*

R. C. Rowan, M.D., Albion, Mich.

Answer.—The occurrence of repeat monstrosities in the same family is not unusual. According to Murphy (Congenital Malformations: Study of Parental Characteristics with Special Reference to the Reproductive Process, ed. 2, Philadelphia, J. B. Lippincott Company, 1947), gross congenital malformations, as recorded upon death certificates, afflict approximately 1 in every 213 individuals who are born alive. About 25% of congenitally malformed persons are stillborn. In families already possessing a malformed child, the birth of a subsequent malformed offspring takes place with a frequency which is in the neighborhood of 25 times greater than that of the general population. In families containing two malformed siblings, the subsequent defective child is more likely to be born later in the family than it is to be the next child in order

of birth to the first defective sibling. In families possessing two or more malformed siblings, the defect in the subsequent offspring has been identical with that in the previous defective sibling in approximately 50% of instances.

ALCOHOLISM

To the Editor:—*What is a definition and what are the symptoms and signs of alcoholism?*

Francis E. McGrath, M.D., Brooklyn, N. Y.

Answer.—Alcoholism is a disease which is characterized by a compulsive drinking of alcohol in some form. It is an addiction to alcohol. The drinking of alcohol produces continuing or repeated problems in the patient's life. The World Health Organization's definition of alcoholism is as follows:

> Alcoholism is any form of drinking which in its extent goes beyond the traditional and customary "dietary" use or the ordinary compliance with the social drinking customs of the whole community concerned irrespective of the etiological factors leading to such behavior and irrespective also of the extent to which etiological factors are dependent upon heredity, constitution, or acquired physiopathological or metabolic influences.

Symptoms of alcoholism are varied and many. The outstanding symptom is the inability of the patient to stop drinking once he has started. Other symptoms are excessive drinking of alcohol on any occasion when the patient drinks, excuses for drinking, drinking on the least provocation, and using alcohol as a sedative or soporific. There are so many varied symptoms that it is difficult to enumerate them all. Signs of alcoholism are usually the signs of excessive drinking and may be manifested by the signs of the acute phase—incoherence, boisterousness, amnesia, loss of appetite, polyneuritis, liver disease, and the end-points such as the chronic brain syndrome associated with alcohol intoxication (Korsakoff's psychosis).

PERIORBITAL SKIN LESION

To the Editor:—*A patient has a small, oval-shaped, macular, yellowish lesion just under the lower eyelid, approximately 10 by 4 mm. in size. There is no other clinical evidence of any disease. What diagnosis and treatment are suggested?* *M.D., Illinois.*

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—In a young person, some xanthomatous process would be suspected. In an older person, xanthoma, sebaceous pseudocyst or cyst, and morphea-like basal-cell carcinoma must be considered. Biopsy should be valuable for diagnosis, after which treatment can be more accurately carried out.

Answer.—The lesion described is probably molluscum contagiosum, a mildly contagious, umbilicated tumor of the skin occasionally found on the eyelids.
When the lesions appear near the lid margin,
conjunctivitis may be present. Lesions are rep

matter of coughing in public and the car
person. In fact, until quite recently he has
very little during the day. He shares the
the director of the school, and in the after
frequently sits in the staff parlor. Under the
circumstances and owing to the care he
takes, it has never been thought that his
was a menace to the health of his associates
tunately, though, this year two cases of tub
have developed in the school. One case is
new boy who had had no connection with
in question; the other is that of a teacher
sat at the dining table with him. The ques
been raised as to whether it is safe to keep
in the employ of the school and, if so, what
precautions should be taken. *M.D., Ill*

Answer.—It is surprising that a man wit
tuberculosis should be permitted on a school
the first place; the fact that he remains an op
after 15 years have gone by is also surprising
ever has the responsibility of continuing the
his present position must be put on the de
especially now that two cases have developed
institution. He should be aided in finding
ment of such a type that the chance of transmi
disease is reduced. He should not continue
in a school. Incidentally, resectional surgery s
be long overdue in this case. If successful, it
enable the employee to return to the school
endangering the health of others.

DIVERTICULUM OF THE URETHRA

To the Editor:—*Several women patients have a severe pussy discharge from the urethra with concurrent enlargement in the region of the urethra itself. Massage evacuates this sacculation. Please indicate the cause and the treatment of this condition.*

Lester Harbin, M.D., Rome, Ga.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—This is an accurate description of a diverticulum of the female urethra. This condition is not uncommon and is very frequently overlooked. These patients will complain of infection and occasionally of stone formation in the diverticulum. The symptoms are usually those of dribbling at the end of urination, local discomfort, and frequency of urination. The treatment is surgical excision of the diverticulum.

Answer.—The most likely condition is a diverticulum of the urethra, and the diagnosis can be made by endoscopic examination, with the extent outlined by a urethrogram. The treatment is a diverticulectomy with plastic repair of the urethrovaginal septum. It would be unusual to have several women patients with diverticulum of the urethra except in a large urologic practice. Therefore, differential diagnosis would seem indicated. An infected urethrocele should be considered, and this is usually associated with a cystocele. Also, it might be a residual infection of a previous abscess of Skene's glands, but the openings of Skene's ducts are on either side of the median line. The above pathological conditions are associated not only with nonspecific infection but frequently with a Trichomonas infestation secondary to this condition in the vagina.

PAIN FOLLOWING HERPES ZOSTER

To the Editor:—*A 66-year-old man had herpes zoster involving the first branch of the left trigeminal nerve in 1952, with residual scarring of the forehead and a fixed dilated pupil on that side. Vision in the left eye is 20/70 corrected to 20/50. Constant burning has been present in the involved area, but most distressing have been 45-minute episodes of severe pain along the same course after eating or chewing. A course of protamine has afforded no relief. Is stimulation of the third portion of the fifth cranial nerve an acceptable explanation of the pain along the first portion of the fifth cranial nerve? Is any further treatment indicated?* *M.D., Ohio.*

Answer.—The exact cause of the pain following herpes zoster, particularly in the trigeminal nerve, is unknown. One theory is that there is infection of the posterior root ganglion with secondary changes, although others believe that there may be some alteration in the physiology along the principal thalamic tracts on the way of this nerve centralward. The pain is notoriously difficult to stop. Some patients have had some relief by the injection of Pituitrin, although this consultant has never seen any good results with long courses of Pituitrin. There has been some alleviation of the pain by the use of chlorpromazine. In the past, there has been some relief of the pain in some patients by surgery, although there is no assuredness that this will be permanent. It is essential, if the pain is confined to the ophthalmic division, to cut not only the supra-orbital nerves but also the blood vessels, since it is important to interrupt the autonomic nerve supply as well as the somatic. The cause for the fixed dilated pupil is hard to explain if this was an ordinary herpes zoster. Was there actual involvement of the eye proper with scarring, or was this a neural type of pupillary change which would suggest a lesion, most likely in the mesencephalon? It is not usual for herpes zoster to have an accompanying meningitis and encephalitis. This is why it is so difficult to stop the pain at some simply reached point, such as the supra-orbital region of the forehead, because much of the pathology is central. There is always grave danger in these cases of addiction, and other methods of therapy so as to avoid such an outcome might be used. There have been some reports of breaking the pain pattern by means of electroshock, and in most extreme cases even lobotomy has been suggested to relieve the sting of this intractable pain. What this physician describes is one of the most difficult of all pain patterns known to medicine to eradicate.

ERYTHEMATOUS REACTION TO APPETITE STIMULATION

To the Editor:—*A 2-year-old girl has a peculiar reaction persistently associated with eating or with visual stimuli, which results in salivation. She develops an area of erythema, about 3 to 4 cm. wide and extending from the upper anterior border of the left pinna down across the parotid area and following the course of Stensen's duct to the level of its termination. This erythema is unilateral, on the left side and on the outer skin. Examination of the buccal mucosa at this level shows no erythema, only a questionable edema, and there is no obvious change in the opening of the duct into the mouth. There is no obstruction to salivary flow. This phenomenon is repeatable at will, the color fading rapidly after cessation of the stimulus, only to return immediately a stimulus is again present. Mere observation of a piece of candy, for instance, causes its appearance, a good index for study of the effect of visual and olfactory stimuli on salivation. This has been present since birth, the mother having noticed it while the child was nursing. What is this condition, and can anything be done for it?*

Kenneth D. Rose, M.D., Lincoln, Neb.

Answer.—This is a most unusual manifestation of ptyalism and erythematous reaction around the parotid area and is obviously an excessive vascular reaction in the nature of an exaggerated conditioned reflex, such as is described by Pavlov in his early experimental studies on animals. Both the sympathetic and, particularly, the parasympathetic nerves innervate the parotid and the fifth, the seventh, and the ninth cranial nerves supplying fibers from the tympanic and otic plexuses. What should be a *normal reaction* to the anticipation of food becomes overexaggerated, owing to some strange factor which one finds it difficult to explain. This is not an allergy, because it is nonspecific to any particular food; again, it is purely localized to one side of the face; nor is it a type of reaction which occurs with a stone in the parotid duct.

Belladonna and the atropine preparations should help to diminish salivation; if with the growth of the child this strange phenomenon continues, one can visualize possible operation with the transection of the complex nerve supply to the parotid gland, particularly the auriculotemporal nerve which carries both parasympathetic and sympathetic fibers from the otic and tympanic ganglions.

LIGHTNING PAINS DUE TO TABES DORSALIS

To THE EDITOR:—*A 53-year-old woman was given a diagnosis of tabes dorsalis in 1938, at which time Mapharsen and Tryparsamide were prescribed. She never has been entirely free of nighttime pain, and in the past six months lightning pains have been steadily getting worse. The pain can be controlled by the administration of 15 mg. of prednisone daily, but it is felt that the continuation of this therapy is inadvisable. Results of the spinal fluid serology, spinal fluid protein, blood Kolmer, and blood Venereal Disease Research Laboratory tests are all negative, and the result of the blood Kline test is weakly positive. Would a course of penicillin be advisable in controlling the intense pain of this patient?*

M.D., Kansas.

ANSWER.—Lightning pains due to tabes dorsalis often represent a residual which persists after adequate antisyphilitic treatment. This seems to be the case in the patient in question. Nothing is to be gained by giving the patient any more penicillin or any other form of treatment for syphilis. The proper procedure at the moment is to search the patient for foci of infection and to remove any of these which can be found, e. g., an abscessed tooth and infected tonsils, and there should be adequate treatment of a urinary infection. The mechanisms which trigger lightning pains and the effect of steroid hormones on these are discussed by Moore (*Am. J. Syph.* 37:226, 1953).

All other things being equal, there is probably no reason why this patient should not continue on a small maintenance dose of an appropriate steroid hormone, although 15 mg. of prednisone on a long-term basis represents a potentially dangerous dose; an effort should be made to reduce this to 5 to 7.5 mg. daily. An occasional patient who suffers severely from lightning pains in the temperate zone may find relief in winter by removal to Florida or southern California. As a last resort, the patient might be referred to a neurosurgeon for discussion of the possibility of relief by means of anterolateral chordotomy.

ULCER TREATMENT AFTER SURGERY

To THE EDITOR:—*A 23-year-old man was admitted through the emergency room with a three-or-four-hour history of severe abdominal pain. On physical examination his abdomen was found to be boardlike, and an upright film of the abdomen showed free air under the leaf of the diaphragm on the right side. The patient was taken to the operating room immediately, and under general anesthesia a laparotomy was undertaken. A 3-mm. perforation was present in the anterior surface of the duodenum just distal to the pylorus. This was inverted and closed with three Lembert sutures of silk. The patient made an essentially unremarkable recovery after several days of mild ileus and treatment with appropriate electrolyte solutions administered intravenously. He was discharged 12 days later. Careful questioning failed to reveal the typical history one usually finds in a peptic ulcer patient. He had a little mild indigestion "when he traveled" but denied smoking and drinking. He seemed to be a quiet, temperate individual without any outward signs of anxiety such as one frequently sees in ulcer patients In some clinics the phenomenon of perforation of a duodenal ulcer in a patient without previous symptoms suggestive of duodenal ulcer is regarded as an indication for either immediate or subsequent subtotal gastrectomy. One argument advanced for this treatment is that, if a patient manifests perforation as his first "symptom" of duodenal ulcer, a severe ulcer diathesis exists and, if not operated on, he will certainly go on to one of the complications of peptic ulcer disease. (The occurrence of perforation without previous symptoms of ulcer disease is a well-known phenomenon.) Other schools, along more conservative lines, feel that a trial at medical therapy is justified even though perforation, a classic indication for surgery, has occurred; that is, definitive surgery, such as a subtotal gastrectomy, is deferred temporarily or indefinitely. What is the majority opinion today as to the further treatment of a patient such as has been described?*

Robert G. Small, M.D., Stamford, Conn.

ANSWER.—A patient who has had a ruptured duodenal ulcer without previous ulcer symptoms and who has had a successful repair of the perforation should not have a definitive ulcer operation at a later date without a proper evaluation. The patient's ulcerogenic diathesis should be evaluated by a 12-hour night secretion. The amount of hydrochloric acid secreted should then be calculated in terms of milliequivalents by multiplying the amount of gastric juice secreted in liters by the number of clinical units of hydrochloric acid calculated in the 12-hour secretion. If the 12-hour ight secretion should yield milliequivalents of 35 or ver. that patient should be regarded as having an lcerogenic diathesis. Since this patient had no warnng sign of ulcer pain and therefore would be be diffiult to follow except by numerous repeated x-rays, it vould be best to subject him to proper ulcer operation. The patient should be placed on ulcer management or about six months, and an x-ray of the stomach hould be repeated at intervals of three months. If an ılcer is present on x-ray, this patient should also unlergo an operation. An x-ray may not be diagnostic ecause of the defect existing after the repair of he rupture. Under these circumstances, the decision vould be based entirely upon the calculation of the nilliequivalents of hydrochloric acid secreted during .2-hour continuous secretion. If the patient does not ave an ulcerogenic diathesis and his x-ray follow-up emains normal, then the episode of the rupture should e regarded as an isolated experience, and the patient hould be followed medically for an indefinite period ntil criteria develop that would indicate ulcer surgery.

TEST FOR CHOLINESTERASE ACTIVITY

To the Editor:—*Is there a simple test for determining blood cholinesterase activity in workers exposed to organic phosphate insecticides? Is the test-kit manufactured by the Biological Test Product Corp., Roselle, N. J., satisfactory?*

Hollis T. Rogers, M.D., Winnsboro, La.

Answer.—The test-kit mentioned utilizes the bromthymol color test for determining blood cholinesterase activity. Hydrolysis of a substrate acetylcholine iodide by the enzyme in a drop of finger-tip blood is measured by the change in color of the indicator. The blood is diluted with bromthymol blue in a standard (white blood cell dilution, 1:20) blood-diluting pipet, and the mixture is placed in a small serum bottle. To this is added the substrate, after which the sample is incubated in the axilla of the person being tested (or in 98 F water bath) for 20 minutes. The per cent of normal average human cholinesterase is read directly by comparing the individual point color with a color chart which shows the percentage of activity represented by each color. The manufacturer of this kit acknowledges that the symptoms of cholinesterase inhibition do not appear until the blood cholinesterase level has dropped to 30% of normal or lower. (For further information see Limperos and Ranta: *Science* 117:453, 1953.)

The reliability of the testing method depends upon the capability of the person interpreting the cholinesterase values. It has been found that the "normal" cholinesterase value varies from one person to another. It has been suggested that a series of tests be made on individuals coming into contact with organic phosphate materials so that a normal value for the person may be determined.

TWITCHING OF MUSCLES

To the Editor:—*Is there any drug that can be taken for fibrillary twitching of voluntary muscles present off and on throughout the day and night?*

M.D., Illinois.

This inquiry has been referred to two consultants, whose respective replies follow.—Ed.

Answer.—It is difficult to discuss treatment for fibrillary twitchings in the absence of any further clinical information indicating the basic cause of the twitchings. These twitchings can be caused by illnesses as serious as amyotrophic lateral sclerosis, but they also may be benign. occurring in relation to fatigue or just spontaneously. Usually, very little can be done pharmacologically for these twitchings, but it may be worthwhile to administer quinine in a dosage of 0.3 Gm. twice to three times daily after meals. Occasionally this drug relieves cramps and twitchings in striated skeletal muscle.

Answer.—This consultant is not able to recommend any drug that would prevent fibrillary twitching of voluntary muscles. Fibrillary twitchings may represent disease of the anterior horn cells, and, if so, there is no way known to eliminate them. On the other hand, perfectly normal individuals often have occasional twitching of muscles when they are especially tense or fatigued. In this case rest and recreation. rather than drug therapy, would be the appropriate treatment.

SYSTEMIC LUPUS ERYTHEMATOSUS

To the Editor:—*What is the most recent treatment of lupus erythematosus? The diagnosis has been established beyond any doubt, and so far only prednisolone has been of any relief. The patient is a 29-year-old housewife who has been afflicted for about 12 months; the disease is generalized.*

M.D., Illinois.

Answer.—The most recent treatment recommended is the administration of freshly drawn blood to patients with systemic lupus erythematosus. Heparinized compatible blood, 30 cc. freshly drawn, is injected intramuscularly three times weekly for several weeks, after which the dose is diminished. By using the leukocyte fraction alone, smaller doses may be employed. It is thought that the leukocytes contain a large quantity of a substance which is destroyed in systemic lupus erythematosus and which normally inhibits the action of an enzyme that depolymerizes desoxyribonucleic acid. It is difficult, however, to evaluate a new form of therapy for a condition such as systemic lupus erythematosus. The usual treatment consists of a combination of corticosteroids and whatever supportive therapy is indicated, including as much rest as possible.

POLIOMYELITIS IMMUNIZATION DURING PREGNANCY

To the Editor:—*A patient developed poliomyelitis three days before term delivery in 1954. The baby which was taken to another hospital and later given poliomyelitis immunization did not develop poliomyelitis. The mother has been left with a paraplegia and is now again pregnant. Should she be given immunization against poliomyelitis now for protection of her second child, or will her acquired immunity protect the baby?*

M.D., Nebraska.

Answer.—Pregnant women are at increased risk of contracting poliomyelitis, owing not only to greater exposure but probably also to increased susceptibility. Immunization of the pregnant woman with poliomyelitis vaccine is therefore strongly indicated for protection of the woman herself, rather than primarily for passive protection of the newborn infant. In the young infant, significant levels of passively transmitted maternal antibody are detectable for only about three or four months. Recent studies indicate that active immunization of the infant with poliomyelitis vaccine may be started as young as 2 months of age.

Most of recent poliomyelitis epidemics have been shown to be due to type 1, poliomyelitis virus. Small outbreaks or sporadic endemic cases may be caused by types 1, 2, or 3. For the individual patient mentioned in the query, only by specific poliomyelitis neutralizing antibody tests could it have been determined which type caused her illness in 1954 and whether she had also acquired antibody to the remaining two types by previous inapparent infection. Active immunization of this patient with poliomyelitis vaccine is thus indicated, since she could still be susceptible to one or two types of poliomyelitis virus.

GRAFTING MUCOUS MEMBRANE TO THE LARYNX

To the Editor:—*The query in* The Journal *for July 20, 1957, page 1421, regarding the desirability of grafting turbinate mucosa, which has about the same thickness as septal mucosa, was noted with interest. Shrinkage of mucosa is very little when the full thickness is used, irrespective of the donor site. Another factor to be considered is that turbinate mucosa is spongier than buccal mucosa, because the turbinate mucosa rests upon a mass of lymphoid tissue which contains many mucous glands that open upon the surface of the mucosa. Without knowing any of the specific details, it would seem that buccal mucosa would be more desirable than turbinate mucosa.*

It is most desirable to take buccal mucosa away from the corner of the mouth. Of course, a great deal concerns the amount of mucous membrane that would be required for the graft. The one factor that must be kept in mind is that mucosa should not be cut over or around the opening of the parotid duct. Any other part of the buccal surface should be satisfactory.

Casper M. Epsteen, M.D., D.D.S.
25 E. Washington St.
Chicago 2.

TREATMENT OF ACNE

To the Editor:—*In the Queries and Minor Notes section of* The Journal *for July 13, 1957, page 1291, three consultants discuss prevention of the premenstrual flare-up of acne. The only point of agreement among them is that two suggest the use of a diuretic "for a few days, beginning as soon as water retention is evident." When water retention is evident, treatment is too late. I would like to call attention to a recent study by Kalz and Scott (*A. M. A. Arch. Dermat. 74:493-503 *[Nov.] 1956), which showed that flare-ups could be prevented in most cases by giving ammonium chloride, preferably in a proprietary form, for 10 days prior to the menses. These investigators also found that water retention (measured by hyaluronidase and histamine wheal-resorption rates) tended to disappear on this diuretic regimen. This has been long assumed but never before proved.*

Harry Wiener, M.D.
45 Saw Mill River Rd.
Yonkers, N. Y.

The above comment was referred to a consultant whose reply reads as follows.—Ed.

To the Editor:—*There is no unanimity of opinion regarding the prevention of premenstrual papules and pustules of acne. The answers of the three consultant demonstrate this amply. However, it should be pointed out that one consultant recommended the use of ammonium chloride and that only one consultant advocated waiting until water retention became evident. The use of ammonium chloride has been accepted for many years and is widely employed in the prevention and treatment of premenstrual water retention. The article by Kalz and Scott claimed that a proprietary tablet containing ammonium chloride, homatropine, caffeine, and various fractions of the vitamin B complex prevented premenstrual exacerbations in 80% of 40 patients with acne and 10 patients with miscellaneous dermatoses, all of whom usually suffered flare-ups of their cutaneous conditions during the premenstrual period. However, excellent results were obtained in only 56% of the cases. Unfortunately, the criterion used for judging the benefit as "excellent" was not defined. Results obtained with ammonium chloride alone were not significantly inferior. It should be stressed that premenstrual acne may respond in a given patient to one or more of the many possible approaches or, in some instances, may be refractory to all the known therapeutic procedures.*

WASHINGTON NEWS

FROM THE WASHINGTON OFFICE OF THE AMERICAN MEDICAL ASSOCIATION

PHS Studies Use of Private, Military Hospitals
More Support for Use of Automobile Safety Belts
Tax Bill Hearings Limited to One Month
Folsom Assistant Outlines Views on Health Needs

PHS STUDIES POSSIBILITIES OF CLOSING FOUR GENERAL HOSPITALS

At the request of the Budget Bureau, the Public Health Service will survey four of its general hospitals, selected by the bureau, to determine if the patients could be cared for more effectively and economically in other institutions, such as local or military hospitals.

In announcing the surveys, Deputy Surgeon General W. Palmer Dearing emphasized that no immediate changes are contemplated in the existing program of medical care. "These surveys are objective, fact-finding projects to give up-to-date information of the best way to meet our medical care responsibilities in these four areas," he said.

The hospitals are at Chicago, Detroit, Memphis, Tenn., and Savannah, Ga. During the fiscal year ending last July 1, PHS records show the average daily patient load at the Chicago hospital was 118, and the average number of beds in operation 140. Figures for the other three are: Detroit, 131 average daily patient load and average of 150 beds; Memphis, 82 and 135; and Savannah, 95 and 120. The other eight PHS general hospitals are not included in the survey.

George St. J. Perrot, head of the PHS division of public helath methods, will direct the studies, which will be done by a team of specialists in medical care administration. Surveys start this month and will be completed by the end of November.

Patients at the four hospitals to be studied include American seamen, Coast Guardsmen, U. S. employees injured in line of duty, and some other groups, but not special PHS patients, such as persons with leprosy and narcotic addicts. The PHS estimates that its medical beneficiaries among merchant seamen, Coast Guardsmen, Coast and Geodetic Survey personnel, and dependents number 265,200. Not included in the total are the 4 million federal employees and employees of certain U. S. contractors who are eligible only for treatment of on-the-job injuries.

HOUSE GROUP SUPPORTS USE OF SAFETY BELTS FOR MOTORISTS

Without proposing any specific legislation, a House interstate subcommittee on traffic safety has found that safety belts, properly made and installed, are a valuable safety device and that the motoring public should give careful consideration to their use.

The subcommittee headed by Rep. Kenneth Roberts (D., Ala.) heard a number of medical witnesses during the first session.

In its report, the subcommittee declared: "The subcommittee feels that if the public has an opportunity to review the facts it will recognize the great safety value in using a seat belt. The subcommittee had great faith in the judgment of the American public."

It noted that the government is drafting specifications to establish minimum limitations for seat belts for use in government-owned vehicles.

TAX HEARINGS TO BE LIMITED TO ONE MONTH

The taxation hearings scheduled for early next session, where Jenkins-Keogh legislation will be one of the subjects taken up, will be limited to one month, and an effort will be made to reduce the number of witnesses. These and other details on the hearings were announced by Chairman Jere Cooper (D., Tenn.) of the House Ways and Means Committee.

Physicians will be particularly interested in the outcome of the Jenkins-Keogh section of the hearings. This legislation, supported actively by the American Medical Association and many other groups representing the self-employed, would authorize deferment of income taxes on a portion of income put into restricted annuity programs. Under present law corporations need not pay taxes on money put into annuity programs for their employees, but this advantage is denied to the self-employed.

Mr. Cooper disclosed this additional information about the hearings:

1. Because of the "extremely limited time available," the hearings, will be confined to the period from Jan. 7 to Feb. 7, 1958.

2. Retirement income and annuities (Jenkins-Keogh) will be two of at least a score of separate subjects to be taken up, but only three broad areas will be studied—questions relating to income, estate, and gift taxes.

3. Taxpayers with a similar interest will be expected to designate one spokesman for their group, but anyone may submit a statement for inclusion in the record. "Along this line," Mr. Cooper says, "it is requested that the various organizations which are affiliated with a national organization get together and coordinate their presentation to the committee through a single spokesman." The National Thrift Assembly, headquartered in Washington, D. C., was formed earlier this year to promote Jenkins-Keogh and to represent all groups supporting this legislation.

4. Those desiring to testify should submit their requests to the committee clerk in room 1102, New House Office Building, Washington 25, D. C., no later than Dec. 2, 1957. The request should outline the subject or subjects to be covered and designate the group or groups to be represented. Written statements, those intended both for insertion in the record and as the basis for testimony, should be in the committee's hands by Dec. 15.

In explaining the purpose of the hearings, Mr. Cooper said:

"The hearings will be conducted for the purpose of re-examining the basic policies underlying our tax laws. They will be utilized as a source of information which will guide the Committee on Ways and Means in formulating proposals looking toward revisions of our internal revenue laws in order to obtain a revenue system which is fair, equitable, neutral in impact between dollars of income from similar sources, responsive to changes in economic conditions, and capable of compliance and administration with a minimum of taxpayer and governmental effort, and which will at the same time produce the needed revenues for the Government. These are objectives which we must continually strive to achieve. They require continuing study and effort . . .

"The burden of taxation on our citizens is heavy. It is my hope that some relief from these burdens can be achieved next year as a result of our hearings and study. The combined impact of the individual income tax, the corporate income tax, and the various Federal excise taxes are so great that we are now in the seventh year in which total Federal tax collections have accounted for more than one-fifth of our gross national product. Further, this session of Congress has witnessed the largest Presidential budget in peacetime history."

MEDICAL NEEDS CITED BY ASSISTANT TO FOLSOM

Dr. Aims C. McGuinness, special assistant to Secretary Folsom, has listed what he believes to be some of the future medical needs of the United States. Talking at the dedication of the new chronic disease and rehabilitation facility of Thayer Hospital in Maine, Dr. McGuinness made these points:

Federal aid to medical schools and laboratories—The administration's proposed 225-million-dollar program would bring medical classrooms and laboratories much closer to current and projected needs. "To fail to help meet the needs of medical schools would be the worst kind of false economy."

Health services to ambulatory patients and chronically ill—General hospitals must broaden their services and achieve greater coordination. "There has been a growing conviction among health leaders that the general hospital should make its resources, staff, physical plant and scientific equipment available to the entire surrounding community. . . . In other words, the term 'hospital care' should include not only bed care but diagnostic service and service to ambulatory patients as well."

Rural health—In the more rural areas where hospital facilities might not be available at all, the most essential health services could be provided through diagnostic and treatment centers. (He did not elaborate on how this would be brought about.)

Health aid to the elderly—The principles of voluntary insurance should be applied to the prepayment of medical expenses of a larger proportion of elderly people. "This administration believes that health insurance can advance most effectively through voluntary action. . . ." The PHS plans to develop demonstrations of home-care services, health maintenance clinics, and restorative services.

Hospital care costs—It is essenial that the problem of rising costs of hospital care be solved. Physicians must constantly ask themselves if they are putting a patient in a hospital when he could be served as well or better on an ambulatory basis.

Dr. McGuinness noted that, by 1954, 70% of the national need for beds in general hospitals had been met, but only 12% of the need for beds for patients with chronic diseases had been met. "The major emphasis of the hospital survey and construction program had been in providing facilities for the acutely ill," he told the group. "There had been little emphasis on the health services needed by ambulatory patients and those who were chronically ill and impaired."

He said that in the field of rehabilitation, the picture is much brighter and that the expanded Hill-Burton program will hasten development of additional rehabilitation programs for the disabled and handicapped.

SYMPOSIUM ON ANTIBIOTICS OCT. 2-4

The fifth annual symposium on antibiotics is scheduled for Washington, D. C., Oct. 2-4, when recent discoveries and advances will be reported by medical scientists from the United States and other countries. The program lists 161 papers to be delivered. Joint sponsors of the meeting are the Food and Drug Administration and the journals *Antibiotics and Chemotherapy* and *Antibiotic Medicine and Clinical Therapy*.

A number of new antibiotics not yet commercially available will be described, including sulfocidin, telomycin, and pimaricin. Scientists from Czechoslovakia will report on "antibiolymphins," lymphotropic antibiotics that are combinations of antibiotics with such substances as polyacrylic acids. They are reported to have high affinity for certain body tissues.

Several papers will be devoted to amphotericin, an antibiotic said to be effective clinically in certain difficult infections, including systemic mycoses.

The following panel discussions are scheduled for each afternoon session:

Oct. 2, rheumatic fever prophylaxis, with Dr. B. B. Breese of Rochester, N. Y., as moderator.

Oct. 3, chemotherapy of diseases affecting infants and the aged, with Dr. Burton A. Waisbren of Milwaukee as moderator.

Oct. 4, the present status of antitumor and antiviral antibiotics, with Dr. C. Chester Stock of the Sloan-Kettering Cancer Research Institute as moderator.

SURGICAL COMPLICATIONS OF PREGNANCY

Robert H. Barter, M.D.
and
Irwin W. Rovner, M.D., Washington, D. C.

EXTRAUTERINE surgical complications of pregnancy are uncommonly encountered. However, when such complications do occur they may be of serious significance. Abortion, the delivery of a previable fetus, premature labor, or, in unusual circumstances, the death of the mother may be the ultimate result.

That surgical complications of pregnancy are not common is borne out by the fact that in the five-year period from Jan. 1, 1952, through Dec. 31, 1956, only 41 patients were operated upon at the District of Columbia General Hospital and the George Washington University Hospital for extrauterine complications of pregnancy. Appendectomy was done in 24 cases, salpingo-oophorectomy or oophorectomy in 12, and cholecystostomy, nephrectomy, pyelolithotomy, lysis of adhesions, and cecostomy in one each. During that five-year interval there were 28,067 deliveries at the District of Columbia Hospital and 17,653 deliveries at the George Washington University Hospital, making a combined total of 45,720 deliveries. Thus this complication occurs in less than 0.1% of all delivered patients. The above figures do not include patients upon whom surgery was done for ruptured intracranial aneurysms, as neurological complications of pregnancy are considered to be outside the scope of this paper.

There were two maternal deaths in this series. The first was due to acute pancreatitis occurring in the middle trimester. The second occurred in a patient in early pregnancy as a result of peritonitis from ulcerative colitis with perforation. These two deaths emphasize the potential gravity of surgical complications of pregnancy.

Extrauterine surgical complications of pregnancy, though rare, are likely to be serious. The most frequent such complication, in a series of 45,720 deliveries, was appendicitis. The urgency of the condition and the difficulty of the differential diagnosis are such that it is better to err on the side of unconfirmed diagnosis than to procrastinate and err on the side of missed diagnosis. Twenty-four appendectomies were done in this series, and the diagnosis was found correct in 22. Less frequent complications were torsion of an ovary or uterine tube, intestinal obstruction, acute cholecystitis, and the so-called round ligament syndrome. It is sometimes difficult to make a differential diagnosis between these conditions and others such as uterine anomalies, degeneration or torsion of a myoma, ectopic pregnancy, and premature separation of the placenta which may cause acute abdominal pain. Surgery was necessary in altogether 41 patients of this series. There were two maternal deaths, one from acute pancreatitis and the other from perforation in a patient with ulcerative colitis. Delay in operating is commonly excused by the fear of inducing an abortion, but abortion is less likely to follow after surgery than after procrastination in the face of persistent abdominal symptoms.

From the George Washington University School of Medicine.

Read before the Section on Obstetrics and Gynecology at the 106th Annual Meeting of the American Medical Association, New York, June 7, 1957.

Differential Diagnosis

The most frequent surgical complication of pregnancy is appendicitis. That diagnosis must always be kept in mind in any patient who has nausea and vomiting and has pain in the lower part of the abdomen during any stage of pregnancy. Inflammation of a Meckel diverticulum must also be kept in mind as a diagnosis in any patient whose symptoms are suggestive of appendicitis.

Second only to acute appendicitis is the complication of a twisted ovary or fallopian tube. Torsion of an ovarian cyst is much more common than torsion of the oviduct. From a differential diagnostic standpoint, however, the diagnosis between these two entities is usually not made until laparotomy.

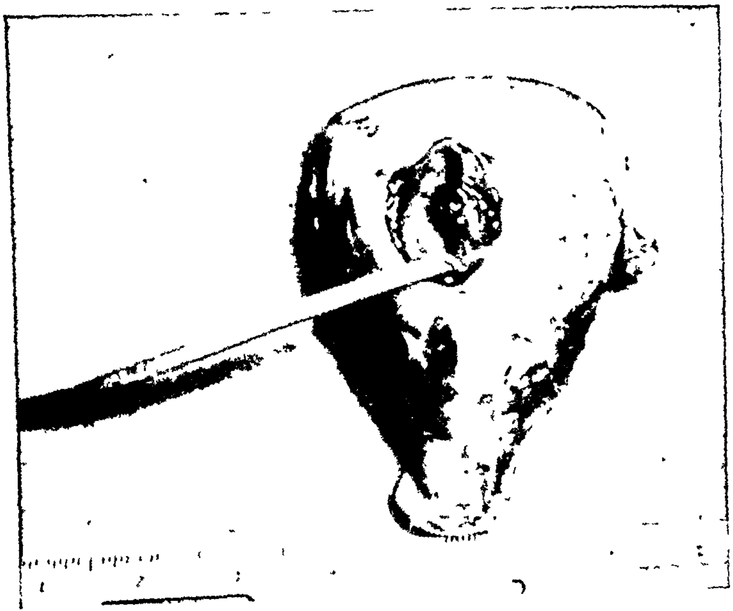

Fig. 1.—Perforation of uterus by means of a catheter in attempt to produce an illegal abortion.

Volvulus of the intestine or intestinal obstruction must be ruled out as a possibility in any pregnant patient who is having nausea or vomiting and cramping abdominal pain and in whom there has been previous abdominal surgery. Incomplete intestinal obstruction during pregnancy may be a particularly difficult diagnostic problem.

Acute cholecystitis can occur during pregnancy, but it is extremely rare. A perforated viscus may also produce an acute abdomen, but other than for ruptured ectopic gestation it is quite uncommon during pregnancy.

There are two other entities, neither of which has been accorded much space in the literature on obstetrics, which may simulate an acute abdomen in pregnancy. The first of these is the so-called round ligament syndrome which many pregnant patients may have from the 14th through the 22nd week of gestation. The pain is due to stretching of the round ligaments. It is usually more pronounced on the patient's right side due to dextrorotation of the uterus. The diagnosis of round ligament pain can usually be verified by palpating the round ligaments and noting that direct palpation of the ligament causes the identical pain of which the patient complains. One should be extremely careful not to overlook the presence of appendicitis in a patient who has tenderness of the round ligaments but the two conditions rarely coexist. Unnecessary appendectomies can be avoided, however, if round ligament pain is kept in mind on each occasion when one is confronted with a pregnant patient who has pain in the right lower quadrant in the absence of fever and leukocytosis. Usually patients with round ligament pain will not have nausea and vomiting, but the pain may be more severe than the pain of early appendicitis.

The second benign condition which may cause a differential diagnostic problem is a gestation in an anomalous uterus. If the pregnancy is in one horn of a bicornuate or didelphys uterus, the patient may have rather acute abdominal pain in the midtrimester due to the inequality of the uterine enlargement in the two halves of the uterus. Round ligament pain or pain from an anomalous uterus should be considered in the differential diagnosis of the acute abdomen during the middle trimester of pregnancy.

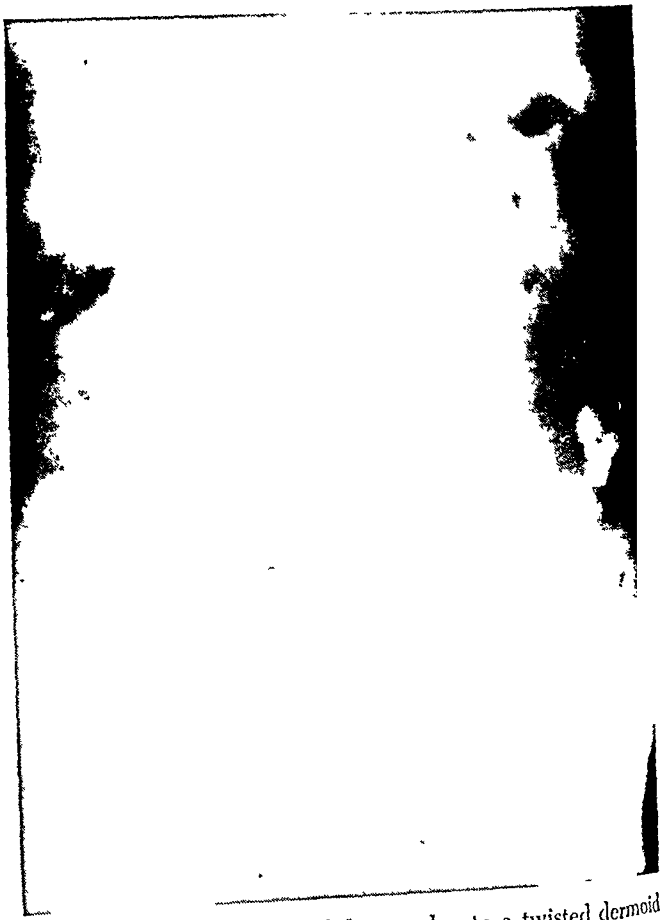

Fig. 2.—Acute surgical abdomen due to a twisted dermoid cyst at the patient's 18th week of gestation. Note the presence of a tooth in the dermoid, thus making positive preoperative diagnosis relatively easy.

Another source of pain in the lower part of the abdomen which may be encountered during the second three months of gestation is degeneration or torsion of a myoma. Such a diagnosis is usually easy to make because of the presence of a painful tumor or tumors in the uterus. As an entity it must be considered in the older pregnant patient who is having pain in the lower part of the abdomen. It may, of course, be the causative agent in the production of an acute abdomen.

From a differential diagnostic standpoint one usually has to consider other uterine causes of pain which may simulate extrauterine pathological conditions. Perforation of the uterus in the first trimester by attempts at abortion may cause an acute abdomen (fig. 1). The possibility of an intra-abdominal foreign body must be considered in all patients with known or presumed illegal abortions. The acute abdominal findings in the patient whose perforated uterus is shown in figure 1 were the result of peritonitis and the presence of the foreign body in the abdomen. After a hysterectomy performed at the District of Columbia General Hospital, the patient recovered.

Premature separation of the placenta with concealed hemorrhage or rupture of the uterus, particularly if the latter occurs during the early part of the last trimester, may simulate an acute surgical abdomen. Patients who have acute toxemia of pregnancy may have severe generalized abdominal pain due to distention of the capsule of the liver. The presence of toxemia usually allows one to make the diagnosis of liver pain rather than a diagnosis of a surgical complication. Rupture of the liver, however, may occur in severe toxemia and should not be overlooked.

Ectopic pregnancy is a condition which is not strictly within the confines of this paper. However, extrauterine gestation is the entity which must be kept foremost in one's thoughts in the differential diagnosis of an acute abdomen in any patient between 15 and 50 years of age who has an amenorrhea of more than six weeks' duration, if her previous menstrual periods had been normal. In addition, ruptured ectopic pregnancy must be considered in any menstruating patient with irregular bleeding who has anemia out of proportion to known external blood loss. If those two facts are kept in mind, the diagnosis of a ruptured ectopic pregnancy should rarely be missed.

Treatment

The management of appendicitis during pregnancy requires clinical awareness that the condition may exist. Any pregnant patient with nausea and vomiting, persistent pain in the lower part of the abdomen which may have localized to the right lower quadrant of the abdomen, and signs of peritoneal irritation must be adjudged to have appendicitis. Unfortunately, procrastination in treatment is almost synonymous with the diagnosis of appendicitis in pregnancy. Early positive diagnosis and prompt appendectomy are the keys to successful management of this problem.

Approximately 90% of the 24 patients in this series who had appendectomies during pregnancy had acute appendicitis. A 10% error in the diagnosis of appendicitis in pregnancy is a permissible margin of error. It is much better to err on the side of an unconfirmed diagnosis of acute appendicitis than to err on the side of a missed diagnosis. Appendiceal abscesses which result from failure of recognition of acute appendicitis may seriously complicate pregnancy and may cause abortion or premature labor as a result of the septic process. The involution of the uterus which occurs after abortion or premature labor further complicates the appendiceal abscess by breaking down the defensive barriers which the body has set up to wall off the abscess. Appendectomy, promptly and properly done with the patient under adequate anesthesia, should rarely result in postoperative abortion. Postoperative hormonal therapy is not essential in properly managed patients. It is well to remember that a patient may still die from a ruptured appendix or its complications.

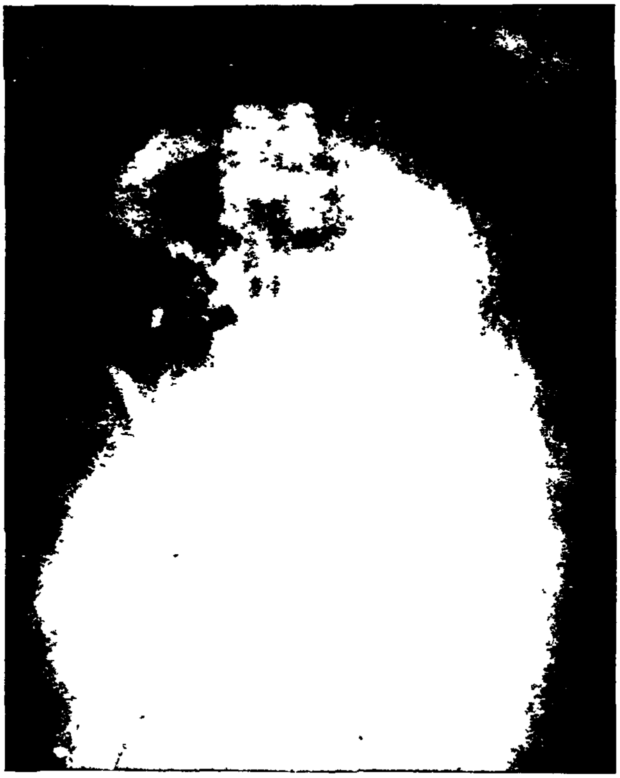

Fig. 3.—Preoperative film showing an ureteral calculus and a fetus of a patient in the 36th week of gestation with acute abdominal pain. The acute symptoms of which the patient complained were originally thought to be due to the calculus.

The diagnosis of appendicitis from the laboratory standpoint is usually not so easy in the pregnant as in the nonpregnant state because of the normally higher leukocyte count in the pregnant patient. Reliance upon laboratory findings rather than upon clinical judgment when considering the possibility of appendicitis in pregnancy may lead to an erroneous impression and delay in treatment.

The diagnosis of a twisted ovarian cyst during pregnancy may be more difficult than that of the diagnosis of appendicitis. The symptoms of the former are usually not quite so definite as are those of appendicitis. However, torsion of an adnexal structure must be considered in any patient who is pregnant and who has persistent severe pain in the lower part of the abdomen. The pain associated with torsion of an ovary is usually more severe than that of appendicitis; vomiting is not as common; and ordinarily an adnexal mass is palpable. If it has been established previously that the patient had an adnexal tumor, the diagnosis is made easier.

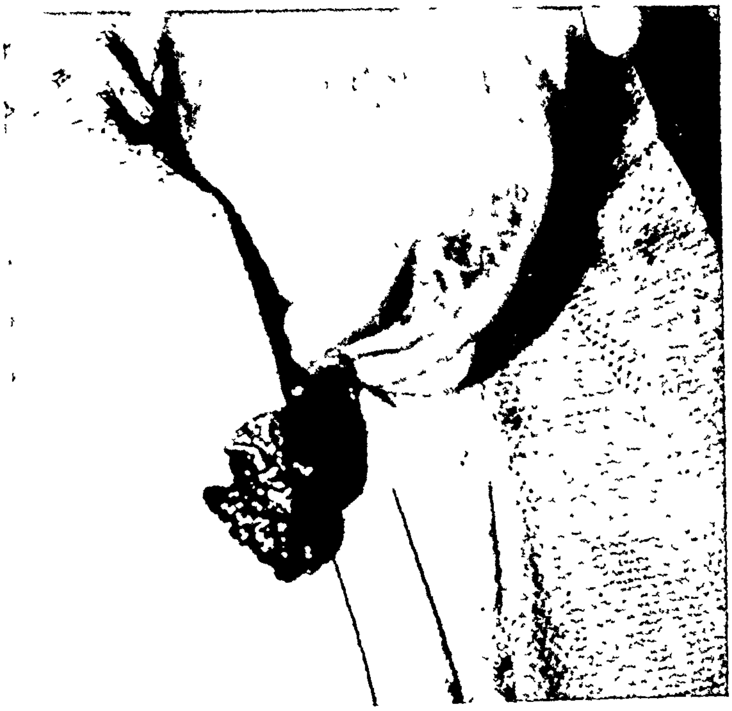

Fig. 4.—Torsion of fallopian tube, shown just after cesarean section, found at exploratory laparotomy in same patient whose preoperative film appears in figure 3 The torsion was found to be the cause of the acute abdomen.

The diagnosis of a twisted ovary is almost infallible if the presence of a dermoid cyst had been established by means of an x-ray during or prior to the gestation. Due to the high "torsion potential" of a dermoid cyst, such a tumor should be removed after the patient's 16th week of gestation if it is asymptomatic and before then if it is causing any symptoms, such as pain.

A flat film of the abdomen should be taken in any patient in whom a twisted adnexal tumor is suspected. The presence of a calcified structure such as a tooth makes the preoperative diagnosis, namely, that of a twisted dermoid cyst, much more certain (fig. 2). Immediate extirpation is imperative when the diagnosis of a twisted dermoid has been made.

If the patient has a twisted ovary or tube, it is important that the infundibulopelvic ligament be clamped before an attempt is made to untwist the infarcted tumor. Failure to observe this precaution may cause the death of the patient by means of a pulmonary embolism. The embolus has its origin from a thrombus in the ovarian vein and may be released when the infarcted cyst and its pedicle are untwisted.

All other persistent adnexal tumors should be removed after the patient's 16th week of gestation, because there is a significant number of patients who will have either serous cystadenomas or pseudomucinous cystadenomas of the ovary or ovaries accompanying an otherwise normal pregnancy. By waiting until the patient's 16th week of pregnancy to do the surgery two purposes are served: 1. If the tumor originally palpated is a large corpus luteum cyst, it will usually be absorbed by the 16th week. 2. The probability of postoperative abortion is greatly diminished after the 16th week of gestation. Postoperative hormonal therapy is not essential.

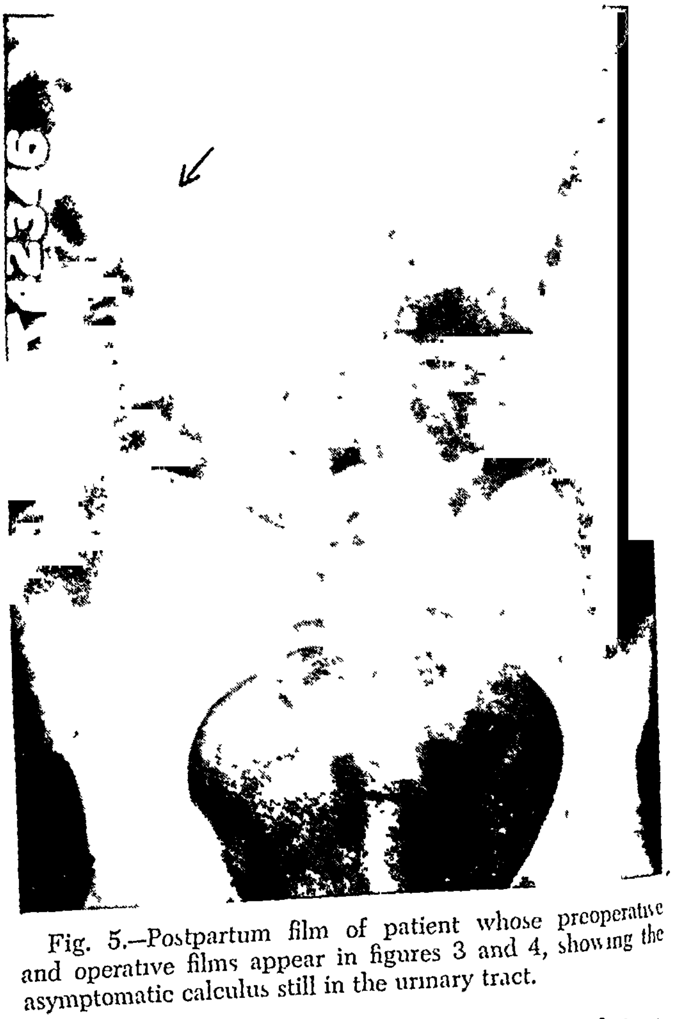

Fig. 5.—Postpartum film of patient whose preoperative and operative films appear in figures 3 and 4, showing the asymptomatic calculus still in the urinary tract.

Volvulus of the intestine or an intestinal obstruction must be given thoughtful cognizance in any patient who has persistent vomiting in pregnancy accompanied by cramping abdominal pain. Most pregnant patients who have vomiting and intestinal cramps of short duration will have gastroenteritis, but the severity of the complication of intestinal obstruction should make the physician constantly include that entity in the differential diagnosis in all patients in this category. If that is done, the diagnosis of intestinal obstruction will not be overlooked. The compromise of the intestine and its blood supply by obstruction is a much more serious complication than is acute appendicitis or a twisted ovarian cyst. Flat films of the abdomen will usually aid in establishing the proper diagnosis. Prompt therapy, whether medical or surgical or both, will be dictated by the subsequent course of the patient, but early active treatment is lifesaving in either instance.

The possibility of pyelonephritis or even more uncommonly the presence of a renal or ureteral calculus must be considered in any patient with persistent abdominal pain. The diagnosis usually is quite apparent due to the presence of pus in the urine, but if there is complete urinary blockage from the affected kidney, the urine may be clear even in the presence of pyelitis. The presence of pus in the urine, fever, and flank pain will usually establish the diagnosis of pyelitis without too much difficulty, and thus exploratory abdominal surgery can be avoided.

Pain due to a renal or an ureteral calculus may be difficult to diagnose, for many calculi are radiolucent. Occasionally the previously established presence of a calculus may lead to a missed diagnosis of some other entity. That problem was encountered recently at the District of Columbia General Hospital in a 48-year-old patient who was known to have an ureteral calculus which antedated her gestation. She was admitted to the hospital in the 36th week of pregnancy with abdominal pain (fig. 3). The proper diagnosis of a twisted fallopian tube as the cause of her pain was obscured by the more obvious diagnosis of ureteral colic (fig. 4 and 5).

Summary and Conclusions

The surgical complications of pregnancy are extremely uncommon. In almost all instances improper or delayed diagnosis will be followed by serious consequences for the fetus, for the mother, or for both. Excellent clinical judgment combined with proper laboratory tests are usually needed if the correct diagnosis of the acute abdomen in pregnancy is to be made and prompt definitive treatment initiated. The presence of pregnancy always makes the diagnosis of an acute abdomen more tenuous and the physician more wary of making what might otherwise be a confident correct diagnosis.

Extrauterine surgical complications of pregnancy are uncommonly encountered. The accurate diagnosis of such complications is usually made more difficult by the presence of pregnancy. Procrastination in the initiation of proper treatment is commonly encountered in the management of the pregnant patient who has an acute surgical abdomen. The failure to initiate prompt therapy is usually due to well-meant apprehension that the treatment may bring about abortion. Pregnancy termination, however, is generally increased in direct proportion to the length of time which is allowed to elapse from the onset of symptoms to the initiation of definitive treatment. The two maternal deaths in our series of 41 patients emphasize the potentially serious significance of all surgical complications in the pregnant patient.

901 23rd St. N. W. (Dr. Barter).

Literature and Medicine.—This Atomic Age of ours has witnessed the downfall of many traditions. Only a few weeks ago I stood once again entranced by the palaces in fabulous Venice and their reflections, wan and faded, on the dead green waters of the canals. Within their walls the tragedy immortalized long ago by Alfred de Musset is still unfolding: suits of armor are rusting away piece by piece; tapestries are fading away blossom by blossom, while the cressets stand empty of candles, and, for lack of powder, the wigs of the lackeys hang limp. There they stand, these ancient palaces, as though waiting to be closed forever or at best converted into prosaic flights of offices. In a like manner modern medical culture has been denying its proud classical heritage and contracting its once vast encylopedic and humanistic domains, to become but an aggregate of ever more and more specialized techniques. Since, as time goes on, the physician exercises less and less his imagination and literary ability, scientific expression is slowly being stifled. As Sir James Barrie, the magnificent creator of Peter Pan, once said, "The man of science appears to be the only person who has something to say just now and the only man who does not know how to say it." And yet, paradoxically enough, the physician, more so than other professionals, has truly artistic strains hidden within his being, though he seldom allows them to burst from their shell for the edification of his fellow men. The physician . . . experiences, like few others can, the desire to relate what he knows or thinks, what he sees or dreams. The proof is that no other profession as medicine has provided so many famous writers. In the course of the world's history, physicians have outshone all other professionals in the writing of romance and philosophy.—Félix Marti-Ibáñez, M.D., Minerva and Aesculapius: The Physician as Writer, *International Record of Medicine and General Practice Clinics*, November, 1956.

SURGICAL CONVALESCENCE—WHEN DOES IT END?

N. Henry Moss, M.D., Cletus W. Schwegman, M.D.
and
F. Curtis Dohan, M.D., Philadelphia

There is wide diversity of opinion among physicians concerning the duration of postsurgical convalescence in uncomplicated cases. The extent of the variation was indicated by the replies of 229 physicians to a questionnaire. Their current practice was indicated in regard to the duration of the convalescent period of otherwise healthy postsurgical patients. Thus, for the same hypothetical case, the recommended interval for return to "light work" after appendectomy varied from 5 to 30 days (average 14 days) and for heavy work from 7 to 60 days (average 28 days). After inguinal herniorrhaphy the recommended time to return to light work ranged from 7 to 84 days (average 24 days) and for heavy work ranged from 20 to 180 days (average 54 days). A wide range of opinion was also expressed for hemorrhoidectomy and cholecystectomy. These wide disparities of opinion were manifested in each of the four groups of physicians. Surgeons tended to recommend earlier return to work than industrial physicians and general practitioners, but each group showed a wide range of opinion. This wide diversity indicates a lack of adequate criteria for determining the duration of convalescence. Recent experience of the Air Force and others indicates that it is safe to return the individual to full activity after a considerably shorter period of postsurgical convalescence than is the current practice of the majority of physicians as judged by insurance statistics and this opinion survey.

Among those questions usually asked by patients anticipating an operation are "How long will I be in the hospital?" and "How long before I return to work?" Experience and statistics have demonstrated that a marked reduction in postoperative hospital stay has occurred in the past 10 years.[1] It is our impression that it has not been associated with an equivalent decrease in the total convalescent time. A study of the literature on surgery reveals that no adequate criteria for the optimum duration of postoperative convalescence have been established.[2] Management of patients in the latter phases of surgical convalescence has been based upon impression and vague concepts rather than objectively supported evidence.

In order to better ascertain current practice in the determination of the length of postoperative convalescence the study presented in this paper was undertaken.

Methods and Response

A questionnaire was prepared and sent to surgeons, industrial physicians, and general practitioners throughout the United States. The questionnaire requested the current opinion of these practicing physicians regarding the proper time for an individual to return to work after certain selected operations of limited magnitude. The questionnaire form for certain general surgical procedures is shown in figure 1. In each of these cases the following assumptions were made: 1. The individual was essentially healthy except for the disability that required the operation. 2. The patient's weight was within normal range. 3. There were no complications. 4. Adequate follow-up medical care was available in the area in which the patient lived. 5. The patient returned to the job which he had held without difficulty for at least one year prior to the operation.

A response to the questionnaire was obtained from 229 physicians. This included 70% of the professors of surgery, 80% of the board certified general surgeons, 52% of industrial physicians, and 41% of general practitioners to whom questionnaires were sent. The replies are reported as percentage of the group samples for each of the respective physician groups. It was apparent in the replies that most physicians tend to think in terms of weeks or months rather than days in determining the time for a patient to return to work.

General Considerations and Types of Operation

Sex and Age of Patient.—The factors of sex and age played only a minor role in determining the total duration of surgical convalescence. In the opinion of 95% of the physicians no distinction in the length of the convalescent period was made between males and females. Evaluation of the age factor in patients with herniorrhaphy revealed that in the opinion of the majority of the physicians the age of the patient made no difference in determining the length of the convalescent period. Of those who made such a distinction, the mean time difference for herniorrhaphy was 12.6 days. Insurance statistics

please fill in the number of days you believe necessary for convalescence from day of operation to return to work in the following cases

DIAGNOSIS	OPERATION	INCISION	SEX	AGE	USUAL NUMBER OF DAYS FROM OPERATION TO RETURN TO FULL DUTIES	
					LIGHT WORK*	HEAVY WORK**
Acute Appendicitis (without perforation)	Appendectomy	McBurney	Male	25		
			Female	25		
		Rt Rectus	Male	25		
			Female	25		
Mixed Hemorrhoids	Hemorrhoidectomy		Male	40		
			Female	40		
Indirect Hernia	Inguinal Herniorrhaphy		Male	25		
			Male	50		
Chronic Calculus Cholecystitis	Cholecystectomy	Right Subcostal	Male	42		
			Female	42		

* Light Work – sitting i e desk job or assembly of small parts

** Heavy Work – lifting 30 to 35 lbs at relatively short intervals or heavier object one or more times per day climbing pushing heavy object operating "heavy" foot pedals jumping running etc

Fig 1 —Questionnaire sent to professors of surgery, board certified surgeons, industrial physicians, and general practitioners of medicine (American Academy of General Practice)

do show a tendency toward prolongation of the convalescent period in middle age and beyond (fig 2).

Appendectomy—The interval between appendectomy and return to light work varied between 1 to 4 weeks and to heavy work from 1 to 10 weeks Great variation existed in all four physician groups. It is noteworthy that most industrial physicians expressed the opinion that patients who have undergone appendectomy should have a longer convalescence than that signified by the physicians in the other groups The average number of days lost from work after appendectomy was 14 days for light work and 28 days for heavy work (fig. 3).

Hemorrhoidectomy.—The convalescent period between hemorrhoidectomy and return to work averaged 13 days for light work and 22 days for heavy work. Wide variation of opinion existed in all physician groups (fig 4).

Inguinal Herniorrhaphy — Great variation of opinion existed in all physician groups in this study. The range for convalescence for a 50-year-old man was 1 to 10 weeks for return to light work and 2 weeks to 6 months for return to heavy work. The average time lost was 24 days for light work and 54 days for heavy work. Results for a 25-year-old man are shown in figure 5. The interval between inguinal herniorrhaphy and the return to either light or heavy work was only slightly influenced by age.

Cholecystectomy.—After cholecystectomy the average number of days lost before return to light work was 22 days and before return to heavy work 45 days. Figure 6 again shows the wide range of opinion.

A summary of the data reveals certain characteristics common to each of the operative procedures included in this study. 1. A wide disparity of opinion as to the length of the convalescent period exists in all physician groups. 2 Return to heavy work in

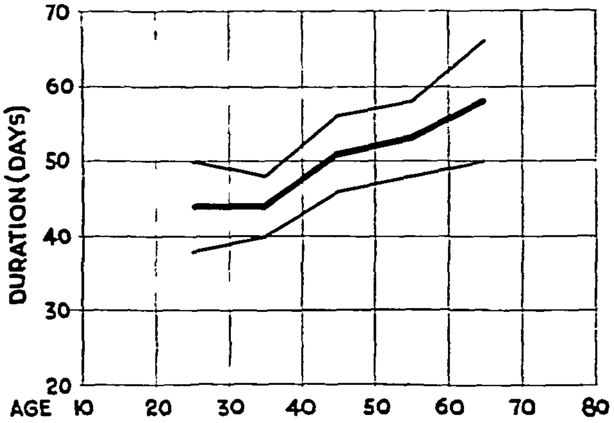

Fig 2 —Apparent effect of age on "period of disability" in male patients with hernia The middle, heavier line denotes the mean, the other two lines, 95% confidence limits.

the opinion of physicians requires approximately twice as long a postoperative convalescent period as return to light work. 3. Surgeons tended to return their patients to work somewhat earlier than did industrial physicians and general practitioners.

Comment

Comparison of the statistics from the Travelers Insurance Company with those of the questionnaire survey shows a close correlation. Compare figures 3 and 7, 4 and 8, and 5 and 9. This would suggest that the opinion of the responsible physician is one of the major factors in determining the time of return to full activity after surgery. It must be pointed out, however, that whereas the correlation is close it is not exactly the same, for the insurance data include some older age groups other than those included in the questionnaire and also there is no distinction in the insurance data between return to light work and to heavy work. In addition, sociological and economic factors play a small role that is difficult to evaluate objectively.

However, the fact remains that there is as wide a range of opinion in the duration of convalescence in the uncomplicated hypothetical cases as that found in insurance data.

Physiological Factors.—Experimental evidence shows maximum wound strength is obtained in two to three weeks.[3] Clinical observation by numerous authorities would support these data in dealing with human beings.[4] Therefore, it appears in an uncomplicated case in an otherwise healthy individual that fear of disruption of the wound after the third week is usually ill-founded. In fact, proponents of early ambulation have stressed the aspect of earlier and improved wound healing as an advance of that concept.

Francis Moore and his co-workers at the Peter Bent Brigham Hospital, Boston, have made numerous studies of the metabolic response during the convalescent period after surgery.[5] Figure 10 indicates in diagrammatic fashion that after even a major surgical procedure, such as resection of the intestine, the adrenal cortical function has returned to normal in approximately 8 to 10 days and that the nitrogen balance is normal by approximately 22 to 26 days. Studies by Hardy and Ravdin [6] and Hardy, Richardson, and Dohan [7] have shown the same pattern of response. It appears that there are no measurable metabolic abnormalities which can explain the long period of convalescence thought necessary by many surgeons and physicians.

Experience with Shorter Convalescence.—Since there are no known metabolic abnormalities or evidences of wound weakness after approximately the third postoperative week in the uncomplicated case, it would be extremely difficult to develop an objective measurement of suitability for return to preoperative activity. It appears that an empirical approach must therefore prevail. The experience of the armed forces[8] suggests that it is "safe" to return the individual to full activity at considerably earlier periods than has been the general practice in the past. Col. D. S. Wenger[9] has reported recently the return to duty of Air Force personnel in the 20-to-29-year age group in an average time of 16.4 days after inguinal herniorrhaphy, 12.1 days after appendectomy, and 12.8 days after hemorrhoidectomy. These figures should be contrasted with the insurance experience previously noted and the average hypothetical times as indicated in the survey of physician opinion.

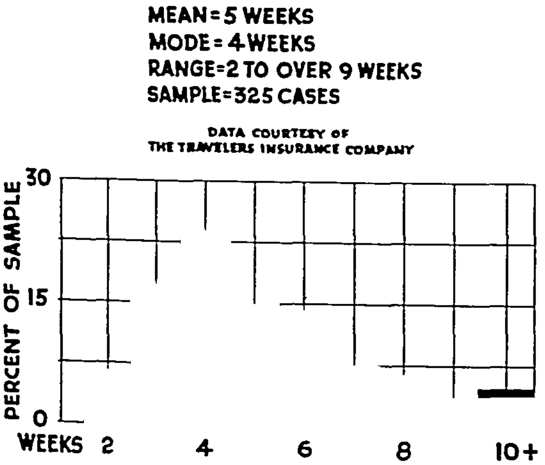

Fig. 7.—"Period of disability" after appendectomy in male patient.

Evidence from other sources and personal communications indicate a similar pattern of shorter total convalescence. One such study conducted in a military installation included 70 individuals with absence of complications from a herniorrhaphy returned to full strenuous activity within 14 to 23 days.[10] The duties and activities included routine training exercises and wrestling. A similar report is available concerning the civilian population. The average return after appendectomy, herniorrhaphy, and cholecystectomy is about one-half the average time quoted in figures 3, 5, and 6.

Summary and Conclusions

Data from military sources indicate that a considerably shortened mean convalescent period is now current practice following specific common surgical procedures. This reduction in the average length of surgical convalescence apparently is not associated with adverse effects or increased incidence of complications.

No adequate criteria for determination of the optimum postoperative convalescent period have been established. To help study the problem a questionnaire survey was made of surgeons, industrial physicians, and general practitioners throughout the United States. The questionnaire

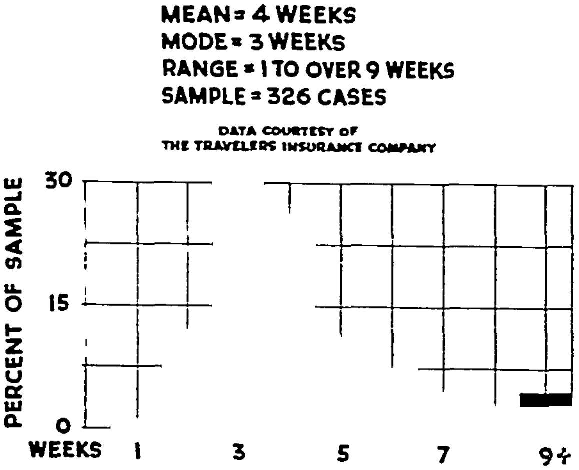

Fig. 8.—"Period of disability" after hemorrhoidectomy in male patient.

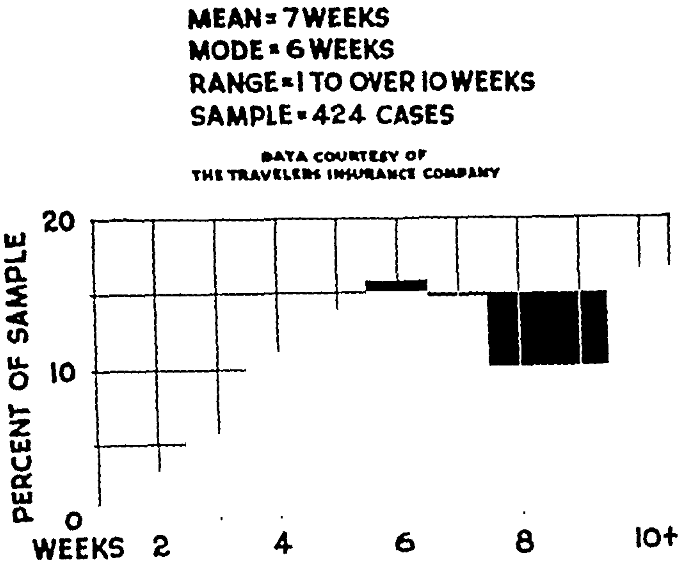

Fig. 9.—"Period of disability" after herniorrhaphy in male patient.

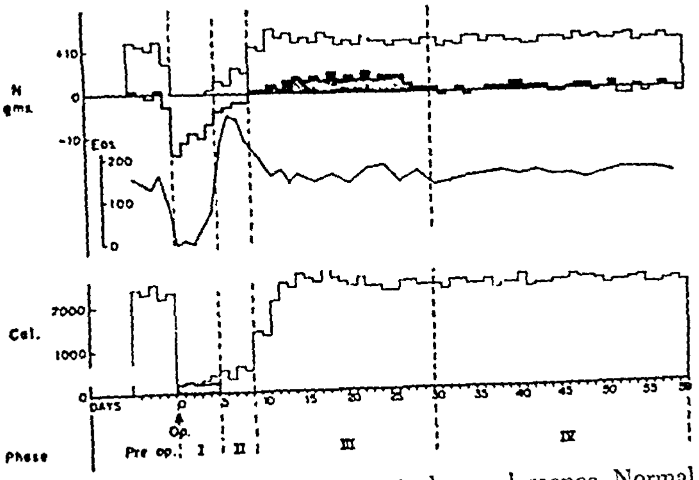

Fig. 10.—Bodily changes in surgical convalescence. Normal response of a normal person to a scale 6-7 trauma (operative). N stands for nitrogen balance in grams. The intake is charted upward from the zero line. The output is charted downward from the top of the intake line. The uppermost line therefore represents the intake, and the distance from there downward to the secondary line represents output by all routes combined. The relation of the secondary line to the zero line represents the balance. If the balance is positive, it is marked as a shaded area above zero; if negative, as a white area, enclosed in a black line, below zero. Eos. stands for peripheral eosinophil white blood cell count and Cal. for caloric intake. The height of the white column represents the caloric content of oral diet. The shaded area represents calories of intravenous infusion. The vertical broken lines indicate the transition periods between the four phases of convalescence described by Dr. F. D. Moore.[5] (Reproduced with permission from Dr. Moore and J. B. Lippincott Company.)

requested their opinion regarding the optimum time for return to work after specific uncomplicated operations on otherwise healthy individuals. Results of the study showed wide variation in opinion among all physician groups for each of the surgical procedures studied. The close correlation of the findings of the survey to insurance statistics reflecting current practice strongly suggests that physician opinion is the major factor for unnecessarily prolonged surgical convalescence.

There is evidence to indicate that the average length of uncomplicated surgical convalescence can be considerably reduced. The extent of this reduction in postoperative convalescence time can be established on the basis of carefully collected studies of large series of surgical procedures and their end-results.

Surgical Treatment of Peptic Ulcer.—There is a place for gastroenterostomy in certain types of large, penetrating, obstructing duodenal ulcers, particularly in patients with low or average gastric acids or in elderly patients with burned-out sclerotic ulcers and low acids. However, the long-term results of such a procedure, even when vagotomy has been added, have not compared favorably with those of partial gastrectomy. In such cases, that is, gastroenterostomy and vagotomy, the incidence of recurrent ulcer was four times that occurring after partial gastrectomy. Moreover, the functional results which followed the procedure of gastroenterostomy and vagotomy presented many unpleasant postoperative sequelae, which were not present to any such extent following gastric resection, and the incidence of dumping disturbances or of disturbances of the nutritional state was about the same in the two groups, regardless of sex.—W. Walters, M.D., Evaluation of Peptic Ulcer Therapy Based on a Five- to Ten-Year Follow-up Study, A. M. A. *Archives of Surgery*, April, 1957.

ETHNOLOGIC ASPECTS OF THE ABO BLOOD GROUPS DISEASE ASSOCIATIONS

Joseph A. Buckwalter, M.D., James H. Turner, Leo Raterman, Robert T. Tidrick, M.D.
and
Lloyd A. Knowler, Ph.D., Iowa City

Statistically significant associations exist between the ABO blood groups and gastric cancer, peptic ulcer, and pernicious anemia. A study of the blood-type frequencies of Negro patients with gastric carcinoma and peptic ulcer showed an apparently higher incidence of gastric cancer in those with blood type A, and of peptic ulcer in those with blood type O. Only continuation and expansion of similar investigations, as well as other research, can adequately test the various hypotheses suggested by these blood group-disease associations.

It has been established that statistically significant ssociations exist between the ABO blood groups and astric cancer, peptic ulcer, and pernicious anemia. ess convincing evidence has been brought forward f associations in diabetes mellitus,[1] rheumatic fever,[2] nd fracture of the hip.[3] The most important question osed by these findings is that of causality. Do the ndings indicate a chance association such as would e found between the falling death rate from tuberulosis and the rising one from automobile accidents, r do they indicate a cause-and-effect relationship?

The strongest evidence against causality has been resented by Clarke and others.[4] Sibships of duodenal lcer patients were studied. Unaffected siblings were ound to have a blood-type-O frequency similar to that oted for their affected brothers and sisters. If there is causal factor responsible for the observed higher ncidence of duodenal ulcer in persons with blood type), a lower frequency of this blood type in unaffected iblings might be expected.

The evidence in favor of causality comes from sevral sources. Data are accumulating from widely seprated geographical areas, confirming the forementiond associations.[5] Differences in ethnologic origins of the opulation groups from which these data have been btained argue against explanations based upon population stratification and other noncausal factors. Evilence for associations between an increasing number f diseases and the blood groups provides additional upport for causality. The finding of a similar association for gastric carcinoma and pernicious anemia, haracterized by an increased incidence in persons vith blood type A for both disorders. in view of the vell-documented relationship of these disorders, suggests a common causal or predisposing factor.[6] The tudies concerned with the secretion of blood group ubstances lend additional support for a causal relaionship.[4]

To find the answer to this question will require not only continuation and expansion of the investigations mentioned above but other researches designed to test the various hypotheses which have been suggested. Most of the data thus far reported have been obtained by retrospective methods. Researches based on prospective instead of retrospective methods are in progress, but, since large numbers of cases are required before the findings become conclusive, considerable time will be needed before they can be expected to yield meaningful results.

A study of the blood-type frequencies of Negro patients with gastric carcinoma and peptic ulcer was undertaken. It was anticipated that such a study would prove helpful in testing the postulate of causality. Findings indicating no association between the ABO blood groups and peptic ulcer and gastric carcinoma in a population group with blood-type frequencies quite different from those of Caucasian population groups would argue against causality. Findings indicating associations would support the postulate of causality.

Materials and Methods

Data were obtained by review of the case records of patients seen at the University of Iowa and Homer Phillips hospitals from 1941 to and including 1956. In order to insure uniformity of the methods employed. all the records were reviewed and the data selected and collected by the authors. Aside from race, diagnosis and blood type were the only two factors determining the selection of cases. Only cases with histological diagnoses were included in the gastric carcinoma group. In more than 75% of the cases, the diagnosis of peptic ulcer was established at the time of surgery. The remaining patients had convincing clinical histories and radiologic evidence of peptic ulcer. These rigid diagnostic criteria, essential to the validity of this study. necessarily meant exclusion of many cases of undoubted but unoperated upon gastric carcinoma and the majority of the patients indicated in the diagnostic files of the record rooms as having peptic ulcer. Two hundred sixty-three cases were selected for study.

Consecutive blood donors at the Homer Phillips Hospital were used as controls. Disease-free relatives and friends of the patients having the same ethnic and

---

From the Department of Surgery, College of Medicine, and the Department of Mathematics and Astronomy, State University of Iowa, and the Homer Phillips Hospital, St. Louis.

cultural background would seem to provide a representative sample of the normal population from which the patients came. No professional donors were included.

The blood-type frequencies observed in the patient and control groups were compared. Differences in the blood-type frequencies of the two groups were examined for statistical significance by the chi-square and difference in percentages methods. Of the 11 possible combinations of the data, comparisons involving the four types (O, A, B, AB) and those involving just two types (O, A) proved to be the most informative. Only the results of the analyses of these two comparisons will be reported. The differences observed between the blood-type frequencies in patients with peptic ulcer and gastric carcinoma were examined for statistical significance in the same way. Considerations relating to collection and analysis of the data have been previously described in detail.[7]

Results

In table 1 are recorded the numbers and percentages of the two patient and blood donor groups with each blood type. Observe the higher frequency of blood type A in patients with gastric carcinoma and the lower frequency of types O, B, and AB, as compared with the controls. However, when the O, A and O, A, B, AB comparisons are made and the differences examined for statistical significance, 0.10< p in each instance, indicating no statistical significance. In patients with peptic ulcer, note the higher frequency of blood type O and lower frequency of A, B, and AB. Again, when the O, A and O, A, B, AB differences are examined for statistical significance, 0.10< p. Now compare the blood-type frequencies observed in the two patient groups. For the O, A differences, 0.05< p <0.10, indicating borderline statistical significance; analysis of the O, A, B, AB comparisons gives 0.10< p.

TABLE 1.—*Numbers and Percentages of Negro Patients and Controls (Blood Donors) with Each Blood Type*

	Blood Type	No.	%
Gastric carcinoma 90	O	40	44.4
	A	31	34.5
	B	17	18.9
	AB	2	2.2
Total		90	100.0
Peptic ulcer 173	O	97	56.1
	A	44	25.4
	B	29	16.7
	AB	3	1.8
Total		173	100.0
Controls 6,722	O	3,304	49.1
	A	1,780	26.5
	B	1,352	20.1
	AB	286	4.3
Total		6,722	100.0

In table 2 are recorded the blood-type percentages and differences in percentages from the controls for Negro and Caucasian patients with gastric cancer and peptic ulcer (Caucasian controls [blood donors] 45.9 type O; 41.6%, A; 9.0%, B, and 3.6%, AB). The mo important point to note is the difference in percenta from the controls of the same magnitude of blood ty A in Negro and white patients with gastric carcinor and of blood type O for both groups with peptic ulc

Comment

The most important findings are the increased incidence of gastric carcinoma in persons with blood type A and increased incidence of peptic ulcer in persons with blood type O in the Negro race, increases of the same magnitude as those found for the Caucasian rac It is possible, perhaps reasonable to expect, but c not be categorically stated, that, if sufficient numbe of cases had been available, similar levels of statistic significance would have been observed for the diffe ences observed in Negroes and Caucasians (for Ca casians—gastric carcinoma 0.01<p<0.02, peptic ulc p<0.001). To answer this question, more data mu be obtained (probably more than 1,000 cases of ea type of lesion). Since it is unlikely that one inves gator will have access to such a volume of data, it w be desirable to be able to combine smaller series purpose of analysis. This will be practical only if ea investigator adheres to the simple but vital requi ment concerning unequivocal diagnoses and accur blood type.

TABLE 2.—*Percentage and Difference in Percentage for Each Type in Caucasian and Negro Controls (Blood Donors) and Patients*

	Blood Type	Patients, %	Difference in % from Contr
Gastric carcinoma			
Caucasian	O	42.2	−3.6
	A	45.8	+4.2
	B	9.2	+0.2
	AB	2.8	−0.8
Negro	O	44.4	−4.7
	A	34.5	+8.0
	B	18.9	−1.2
	AB	2.2	−2.1
Peptic ulcer			
Caucasian	O	53.5	+7.7
	A	36.9	−4.7
	B	7.3	−1.7
	AB	2.3	−1.3
Negro	O	56.1	+7.0
	A	25.4	−1.1
	B	16.7	−3.4
	AB	1.8	−2.5

It is of interest to examine the data in another w as suggested by Morton,[8] employing the method scribed by Woolf.[9] For example, the relative incider of gastric carcinoma in Negro patients with blc type A as compared with the incidence in patients other blood types is determined as follows: from ta 1—patients, 31 with A and 59 with O, B, and AB, compared with Negro controls, 1,780 with A and 4,9 with O, B, and AB. Relative incidence: (31 × 4,9 ÷(59 × 1,780)=1.46.

t is convenient to set up the data on gastric car-
ɔma in tabular form thus:

	Patients		Controls		Relative Incidence in	
	A	O+B+AB	A	O+B+AB	Group A	X^2
o	31	59	1,780	4,942	1.458	2.886
asian	416	492	2,625	3,689	1.187	4.909

Chi-square Analysis

	Degrees of Freedom	X^2	p
Association	1	6.688	<0.01
Heterogeneity between races ..	1	1.107	not significant

he data on peptic ulcer can be set up in tabular
n thus:

	Patients		Controls		Relative Incidence in	
	O	A+B+AB	O	A+B+AB	Group O	X^2
)	97	76	3,304	3,418	1.320	3.276
asian	983	856	2,892	3,421	1.358	20.475

Chi-square Analysis

	Degrees of Freedom	X^2	p
Association	1	23.418	<0.001
Heterogeneity between races ..	1	0.333	not significant

ote, as with the previous method of analysis, the
square value indicates no significance for the
gro carcinoma or ulcer data. However, if the Negro
Caucasian data are pooled, which seems justified
e no evidence of heterogeneity between the races
found, both associations appear significant.

t is to be remembered that 90% of American Ne-
es are part white, Indian, etc. However, a similar
ence of pure ethnic character obtains for Cau-
ian population groups who have provided the data
previous studies in this field. Boyd[10] found the
owing blood-type frequencies in New York Ameri-
Negroes: type O, 48.1%; A, 26.4%; B, 22.8%; AB,
%. The agreement with the blood-type frequencies
erved in the St. Louis Negro blood donor group is
close as that found in the Caucasian population in
erent areas of the United States. It is apparent that
e ethnic populations would provide the most signifi-
t data. Unfortunately, although such populations do
st, their primitive way of life, which would make
ifficult to obtain sufficient numbers of accurately
gnosed cases, has seemingly presented an insur-
untable obstacle to interested investigators to date.

The small number of cases in this study (151 duodenal ulcer, 14 gastric ulcer, and 8 duodenal and gastric ulcers) precluded meaningful examination of the possible differences related to the location of the ulcer. In our previous investigations, no significant differences related to the kind of ulcer were found.[7a]

Summary

A study of 263 Negro patients showed an apparently higher incidence of gastric cancer in those with blood type A and of peptic ulcer in those with blood type O. Although these data are statistically equivocal, they provide support for the causal nature of the previously described association of the ABO blood groups to gastric cancer and peptic ulcer.

Department of Surgery, University Hospitals (Dr. Buckwalter).

Rheumatic Fever.—In the absence of a specific cure for rheumatic fever, there are many therapeutic measures which reduce the severity of the acute attack and improve the patient's chances for recovery and longevity. Prompt eradication of Group A streptococci and continuous prophylaxis against subsequent infection with this organism is perhaps the most important single measure. Also helpful, however, is adequate suppression of the inflammatory process with either salicylates, the adrenal cortical hormones, or both. The least such therapy does is to improve the patient's general condition and reduce the toxic manifestations of the disease that can be harmful and dangerous to the patient with severe carditis. The evidence for a modifying effect of the antirheumatic agents upon ultimate cardiac damage is equivocal but suggestive. The proper control of side-effects of treatment, careful treatment of heart failure with digitalis and diuretics, and the management of the patient's activity are all important supportive measures. Under such management the prognosis for the patient with acute rheumatic fever has been improving steadily.—G. H. Stollerman, M.D., Rheumatic Fever, *A. M. A. Archives of Internal Medicine*, August, 1956.

ORALLY ADMINISTERED PHYTONADIONE IN BISHYDROXY-COUMARIN-INDUCED HYPOPROTHROMBINEMIA

Milton Shoshkes, M.D., Bernard Robins, M.D.
and
Gabriel Yelin, M.D., Newark, N. J.

Oil-soluble phytonadione (vitamin K_1) is the most effective antidote to every known coumarin and indandione derivative. While a dose of 10 mg. given orally is as effective as 100 mg. by vein over an eight-hour observation period, the physician must not be lulled into feeling confident that normal clotting mechanism has been produced. Despite the observed potency of phytonadione, the irregularity of the response to the drug, either orally or intravenously administered, is puzzling. Determinations of prothrombin time must be repeated at frequent intervals, and phytonadione should be readministered if a reversal of prothrombin time is not obtained. When such circumstances do occur, whole blood transfusions are indicated.

At the present time, there are 10 individual drugs capable of inducing hypoprothrombinemia available for use in the treatment of thromboembolic diseases.[1] These compounds are generally classified as either coumarin or indandione derivatives. Though they vary somewhat in speed and duration of effect, their pharmacological effect is identical, in that they all decrease the activity of the circulating prothrombin complex. Oil-soluble phytonadione (vitamin K_1) is the most effective antidote to every known coumarin and indandione derivative.[2] This antidotal quality is in marked contrast to that of the synthetic water-soluble naphthoquinones whose ability to reverse the effect of these compounds was found disappointing and inconstant.[3]

In the United States, phytonadione in emulsified form has been used, until recent years, almost exclusively in parenteral injection as an antagonist to these anticoagulant drugs. It is used, particularly, when a dangerous increase of the prothrombin time exists, threatening or actually inducing bleeding phenomena, or when the anticoagulant effect must be ended quickly. Such a situation might exist if a surgical complication appeared in the midst of anticoagulant therapy. In these situations, phytonadione usually has been administered by the intravenous route. Its innocuousness, despite many hundreds of tests, is manifested by only a single reported serious reaction.[4] This was a severe, but fortunately nonfatal, hemolytic reaction after a single 100-mg. dose of the emulsion.

However, the intravenous route of administration of any medicament is always the least safe of the available routes. Shoshkes and Perelman[5] investigated the feasibility of using the intramuscular route of injection of this emulsion in patients who had received bishydroxycoumarin (Dicumarol). They found that the intramuscular injections had unpredictable effects and that the average change in prothrombin time did not vary greatly from that in the controls. This contrasted with the desired reduction in prothrombin time usually obtained within 8 to 24 hours after the intravenous injection of the same dosage in the same patients.

The effectiveness of the oral route of administration of phytonadione has been under intermittent investigation since Fuller and Barker[6] reported a good recovery of the prothrombin time when they administered 500 mg. of phytonadione by mouth to counter a bishydroxycoumarin-induced hypoprothrombinem Other early workers have used dosages ranging fro 250 to 1,000 mg.[7] with good effect as well. Howeve after further experience with this potent vitamin, t recommended dosage has been reduced to a poi where Wright[8] suggests the use of 10 to 50 mg. o the emulsion administered in food as an effecti antidote to an inadvertent overdosage of any of th coumarin or indandione-type compounds. He h found that excessively increased prothrombin tim will return to safe levels within three to six hours a that a dosage of more than 50 mg. of phytonadione i rarely advisable in that an overdosage might rend the patient resistant to further treatment with th original anticoagulant drug.

There is now available a tablet (Mephyton) co taining 5 mg. of active phytonadione in a stable a easily dispensable form. Theoretically, this shou make oral therapy the method of choice, if only f convenience. Cosgriff[9] evaluated the effect of dos of 2.5 to 20 mg. dispensed via tablets in 75 patie with excessively increased prothrombin times p duced by drugs. He established a prothrombin ti of 35 seconds or less as a limit for safe prothromb penic therapy; he obtained such safe levels in 85% o his patients within 12 hours and in 98%, within hours.

However, it has been our own hospital experience reported in a recent survey of the treatment of 5 cases of acute myocardial infarction,[10] that the hemo

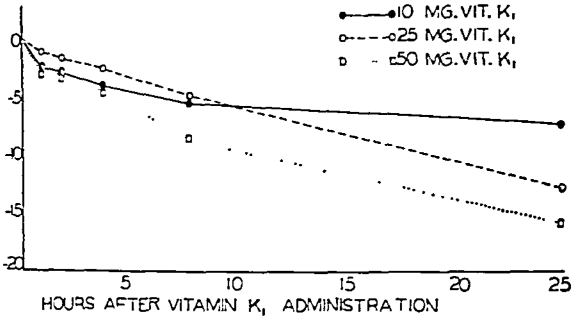
---

From the departments of medicine and laboratories of the Beth Israel Hospital.

agic complications of bishydroxycoumarin therapy re not necessarily related to the prothrombin time els. In all of the cases of hemorrhage complicating shydroxycoumarin therapy, none of the prothrombin nes in question were under the supposedly safe level 10%. It has been our personal practice in treating ch drug-induced bleeding manifestations, therefore, fix a prothrombin time of 50% or more as the anti-morrhagic index. With these thoughts in mind, an tigation of the effectiveness of the tablets of ytonadione in bishyroxycoumarin-induced hypo-othrombinemia was begun.

Investigation of Effectiveness of Phytonadione

Method.—The study included 30 adults who all had en under anticoagulant therapy with use of bis-droxycoumarin. Twenty-eight had been hospitalized or the treatment of acute myocardial infarction and wo for acute thrombophlebitis of an extremity. Blood rothrombin time determinations were obtained daily nd maintained at levels of 10 to 40%. On the con-luding day of therapy with bishydroxycoumarin, sually after weeks of stabilized prothrombin time evels, the phytonadione tablets were given orally in loses of 10, 25, and 50 mg., respectively, to three groups of 10 patients each. Determinations of their prothrombin times were made just prior to the administration of the phytonadione, then, 1, 2, 4, 8, and 24 hours subsequent to this time. No bishydroxy-coumarin was administered during or after this procedure. Oxalated blood was used throughout, and the prothrombin times were determined by the Link-Shapiro modification of the Quick test, using a stable solution of thromboplastin derived from fresh brain and lung tissue (Solu-Plastin).



Response of bishydroxycoumarin (Dicumarol)-induced hypo-rothrombinemia to orally administered phytonadione (vitamin 1).

Results.—The results of the experiment are shown in the figures. The control prothrombin times in seconds are used as the base-line values, and the mean deviations from these values at the observations made after 1, 2, 4, 8, and 24 hours are plotted as negative deflections from the control point. A statistical analysis of the results is recorded in table 1. In a statistical comparison between the mean values for each hour recorded, no significant difference between the effectiveness of the various doses was discernible. Though there is a trend to a lower fall in the prothrombin time at 24 hours after a dose of 50 mg. of phytonadione has been given, the calculation of the standard error of the mean reveals a possibility of one out of three that this is a chance variation. Further analysis of these subjects showed that only 5 of the 10 patients in the group given doses of 10 mg., 9 out of the 10 given doses of 25 mg., and 5 of the 10 given doses of 50 mg. attained a level of over 50% in prothrombin time in 24 hours.

There was a marked similarity in response in all dosage ranges. The first detectable effect of phytonadione is seen certainly within two hours after its administration, with increasing evidence of its potent antagonism toward the bishydroxycoumarin with each time interval observed. Up to the eight-hour level, there is no difference in either speed or effectiveness of response to any of the dosages of phytonadione used. The 24-hour observation, however, points to a definite trend of a more effective fall of the prothrombin time with the doses higher than 10 mg. Though the statistically significant calculations do not conclusively rule out the possibilities of this being a chance observation, there is a larger return toward normal prothrombin time after the 25-or-50-mg. doses have been given.

Comment

A comparison of the effect of the orally administered doses with the effect of doses of 100 mg. of the emulsified phytonadione administered intravenously[5] shows a surprising similarity in the rate and adequacy of the recovery of the prothrombin time. As small a dose as 10 mg. in tablet form is as effective as the 100-mg. dose by vein over the eight-hour observations and is practically as potent after 24 hours. Yet, despite the obvious potency of phytonadione in reversing bishydroxycoumarin-induced hypoprothrombinemia, the irregularity of the response to either orally or intravenously administered phytonadione is puzzling. There was no uniformity in either of these series studied. Up to 50% of the patients studied after either oral or intravenous dosage failed to reach a prothrombin time of 50% or higher in 24 hours. These patients did not possess obvious impairment of function of the liver or kidneys, nor were they in severe and protracted congestive failure which could possi-

TABLE 1.—*Response of Bishydroxycoumarin (Dicumarol)-induced Hypoprothrombinemia to Orally Administered Phytonadione*

	10 Mg.		25 Mg		50 Mg.	
Time in Hr.	Mean Fall in Sec.	Standard Deviation of Mean	Mean Fall in Sec.	Standard Deviation of Mean	Mean Fall in Sec.	Standard Deviation of Mean

24	7.4	4.7	12.9	5.4	16.0	5.1

bly produce a refractory increase in prothrombin times. The answer to this problem must await the knowledge of the mechanism of action of the coumarin drugs upon the prothrombin complex and the function of phytonadione in this reaction. This does emphasize the need for close observation of the patient who has been given phytonadione to counter an anticoagulant drug.

After the physician has administered phytonadione, a false sense of security may lull him into feeling confident that a normal clotting mechanism has been produced when, actually, the prothrombin time may be little changed by a dosage that has usually been effective in his hands. Determinations of prothrombin time must be repeated at frequent intervals and phytonadione should be readministered if a reversal of prothrombin time is not obtained. If this reversal is not forthcoming, whole blood transfusions are indicated. The availability of heparin for reinstituting anticoagulant therapy should alleviate any concern of inducing a state of resistance to the original coumarin or indandione drug.

Gamble and his co-workers,[3a] as well as Toohey,[11] have suggested general courses to follow in treating the effects of the inadvertent overdosage of the coumarin and indandione drugs. The availability of an effective tablet for oral use has simplified this treatment and we present in table 2 a general outline of phytonadione therapy, sufficient to handle the usual situations encountered. The oral dose of 10 mg. is recommended as treatment for excessive induced hypoprothrombinemia without hemorrhagic phenomena. When minor hemorrhagic phenomena occur, such as microscopic hematuria or subcutaneous ecchymosis, a dose of 25 mg. is given by mouth if the patient is in good condition, or by vein if gastrointestinal function or absorption has been impaired by disease. This higher dosage is to insure the reversal of the prothrombin time to at least 50% of normal since the coagulation defect is not necessarily in mathematical relationship to the level of prothrombin. Such doses should be repeated at eight-hour intervals if the reversal of prothrombin time has not been obtained.

TABLE 2.–*Suggested Dosages and Routes of Administration of Phytonadione in Antagonizing Induced Hypoprothrombinemia*

Hemorrhagic Phenomena	Prothrombin Time Levels, %	Phytonadione Dosage		
		Amount, Mg	Route	Frequency, Hr
None	Less than 5	10	Oral	24
Minor	Less than 50	25	Oral or intravenous	8
Major	Less than 50	50	Intravenous	4

With major and life-threatening bleeding episodes, a dose of 50 mg. of emulsified phytonadione by vein is indicated; repetition every four hours, as deemed necessary by repeated determinations of prothrombin time, is recommended. If a reversal of the induced hypoprothrombinemia is not speedily apparent, transfusions should be resorted to. There seems little reason to avoid the intravenous use of this drug in view of the wide experience confirming its safety af such administration. In urgent situations, the sever of the hemorrhage sustained by the patient may eas interfere with the speed and completeness of t absorption of an orally administered dose, and preci time may be wasted in such a mode of therapy. Aft successfully reversing each of the above hemorrhag situations, if the anticoagulant therapy is to be re stituted, heparin can readily tide the patient over unt an adequate increase of the prothrombin time reached again.

Summary

A quantitative comparison between the effectivene of doses of 10, 25, and 50 mg. of phytonadione (vit min K_1) administered orally in tablet form to separa groups of 10 persons each, rendered hypoprothro binemic by bishydroxycoumarin (Dicumarol), sho a similar effectiveness of all dosages in reducing t increased prothrombin times at intervals of 1, 2, and 8 hours after administration. At 24 hours aft administration, the 10-mg. dose was somewhat le effective than the higher dosages. The effectiveness orally administered and intravenously injected pre arations are similar in all respects. Using 50% pr thrombin times as the index of return to a norm coagulation mechanism, only 5 of the 10 patie given doses of 10 mg., 9 of the 10 given doses of mg., and 5 of the 10 given doses of 50 mg. returned normal in 24 hours. This failure emphasizes the ne for repeated observations of the prothrombin time the treatment of inadvertent overdosage of dru induced hypoprothrombinemia. In treating such dru induced hypoprothrombinemia, oral administration phytonadione is the method of choice in all but t most urgent situations.

505 Elizabeth Ave. (8) (Dr. Shoshkes).

AZACYCLONOL (FRENQUEL) HYDROCHLORIDE IN THE TREATMENT OF CHRONIC SCHIZOPHRENIA

A DOUBLE-BLIND, CONTROLLED STUDY

Theodore M. Odland, M.D., Norwich, Conn.

Therapeutic changes most frequently observed in patients taking azacyclonol hydrochloride were disappearance of hallucinations and lessening or disappearance of delusions, false ideas of reference, assaultiveness, agitation, and seclusiveness. Azacyclonol can be said to have a statistically significant effect in that 61 patients improved after drug therapy as opposed to 28 after use of the placebo. There were no untoward reactions attributable to the use of azacyclonol.

The purpose of this study is to evaluate the effect of azacyclonol (Frenquel) hydrochloride therapy in chronic schizophrenia with respect to delusions, hallucinations, ideas of reference, and behavior. Previous investigators have examined the pharmacological action and significance of this drug.[1] The animal studies have included those of the rabbit, mouse, rat, cat, dog, and fish.[2] Uncontrolled studies have indicated benecial results in patients with schizophrenia and delirium tremens.[3] Other studies have compared the results of azacyclonol therapy alone and in combination with reserpine, chlorpromazine hydrochloride, and electroshock.[4] Prior double-blind studies include one with 40 moderately disturbed psychotic patients,[5] another with 64 psychotic female patients,[6] and a third with 350 psychotic patients.[7]

In this study, 171 psychotic patients with chronic schizophrenic reactions were treated for a period of 12 weeks, divided into three consecutive treatment periods of 4 weeks each. These patients had been mentally ill for from 1 to 33 years with an average of 13 years. They had been hospitalized continuously in a state mental hospital for from 1 to 27 years with an average of 10 years. Their ages ranged from 17 to 59 years with an average of 41 years. Of these, 130 were women and 41 were men. They were all residents of the continued treatment service of the Norwich State Hospital, Norwich, Conn. Previous treatment had included varying combinations of electroshock, insulin coma, chlorpromazine, and reserpine therapy.

Prior to treatment, the patients were selected by the ward psychiatrists who filled out a form for each patient indicating the name, age, sex, duration of illness, duration of continuous hospitalization, type of schizophrenic reaction, type of delusions, presence or absence of ideas of reference, types of hallucinations, and behavior pattern. Two equivalent groups (group I and group II were formed by employing the information on the ward psychiatrists' forms. Group I received azacyclonol (100 mg. once daily, five days weekly) the first four weeks, a placebo (identical to azacyclonol in size, color, and shape) the second four weeks, and azacyclonol the third four weeks. Group II

From Norwich State Hospital. Dr. Odland is now at the Eastern Pennsylvania Psychiatric Institute, Philadelphia.

Read before the Connecticut District Branch of the American Psychiatric Association, Undercliff Hospital, Meriden, Conn., Feb. 28, 1957.

received a placebo the first four weeks, azacyclonol the second four weeks, and a placebo the third four weeks.

The pharmacist prepared, for each patient, a bottle that held just enough tablets for four weeks. Physicians and nurses were told that some of their patients would receive azacyclonol and some a placebo, but they were not told that there would be reversals of the groups at four weeks and again at eight weeks. Patients were told only that they were receiving a new medicament. The use of all other medicaments was discontinued the day before this project started; the only extra medicament whose use was allowed throughout the 12-week period was paraldehyde as needed for sedation of very disturbed patients.

Group I	5	0	0	0	0	2	1	0	2
Group II	5	0	0	3	0	3	0	0	1

Results of treatment with azacyclonol and placebo. Group I received azacyclonol first four weeks, placebo second four weeks, and azacylonol third four weeks. Group II received placebo first four weeks, azacyclonol second four weeks, and placebo third four weeks. Further explanation of the categories, by example: Category 3 (IWI) indicates that the patient improved the first four weeks, became worse the second four weeks, and improved the third four weeks. Category 18 (UWI) indicates that the patient's condition was unchanged the first four weeks, became worse the second four weeks, and improved the third four weeks.

Nursing supervisors made weekly written reports on the behavior of the patients as well as unrequested reports on particularly significant changes. Ward psychiatrists made written reports at four-week intervals (on the ward psychiatrists' form described previously); they also made unrequested comments on particularly significant changes. The data were then evaluated and this report was prepared.

Each patient was classified as improved (I), unchanged (U), or worse (W) for each of the four-week periods and placed in one of 27 categories, as shown in the figure. Changes most frequently observed in those patients classified improved were disappearance of hallucinations and lessening or disappearance of delusions, ideas of reference, assaultiveness, agitation, and seclusiveness. Conversely, those changes most frequently observed in those patients classified worse were aggravation of the above criteria. Patients who were classified unchanged actually showed some changes but only of a minor degree. There were no untoward reactions attributable to the use of azacyclonol.

Improvement (see figure) in relation to azacyclonol therapy is indicated in group I by categories 1, 2, 3, 4, 6, 13, and 18 and in group II by categories 11, 15, 17, 20, 24, and 26. Improvement in relation to use of the placebo is indicated in group I by categories 11, 15, 17, 20, 24, and 26 and in group II by categories 1, 2, 3, 4, 6, 13, and 18. Changes with no particular relationship to the use of azacyclonol or placebo are indicated in group I and in group II by categories 5, 7, 8, 9, 22, 23, and 27.

Deterioration in relation to azacyclonol therapy is indicated in group I by categories 14, 19, 21, and 25 and in group II by categories 12 and 16. Deterioration in relation to use of the placebo is indicated in group I by categories 12 and 16 and in group II by categories 14, 19, 21, and 25. Patients who remained essentially unchanged are indicated by category 10.

In tabulating the above information (see table) several interesting facts become apparent. After azacyclonol therapy, 61 patients improved and 11 became worse. After use of the placebo, 28 patients improved and 8 became worse. Changes with no particular relation to use of azacyclonol or placebo occurred in 25 patients and 38 patients remained essentially unchanged.

Of those patients improved after azacyclonol therapy, the average age was 40 years with a range of 15 to 55 years. The average duration of illness was 11 years with a range of 1 to 28. The average duration of continuous hospitalization was 8 years with a range of 1 to 23. Of these 61 patients, 11 were men and 50 were women.

Tabulation of Results of Treatment

Response	Group I	Group II	Total	%
Favorable to azacyclonol therapy	37	24	61	36
Favorable to placebo	15	13	28	16
Unfavorable to azacyclonol therapy	7	4	11	6
Unfavorable to placebo	2	6	8	5
No particular relationship	6	19	25	15
Unchanged	18	20	38	22
Totals	85	86	171	100

Comment

Evidence that the two groups were evenly matched is provided in the table. First, of those improved after the use of the placebo, 15 were in group I and 13 were in group II. Second, of those showing no significant change, 18 were in group I and 20 were in group II.

The fact that 61 patients improved after azacyclonol therapy, as compared to 28 after use of the placebo demonstrates that azacyclonol therapy has a significant effect in schizophrenia. Statistically, this is verified by using a fourfold table and calculating chi square, which becomes 13.85 and gives a p value of 0.0005 (a p value of less than 0.05 is adequate to establish a hypothesis). The fact that 37 patients improved after azacyclonol therapy in group I (eight weeks of therapy) and 24 improved in group II (four weeks of therapy) suggests that improvement is a function of the duration of therapy.

Considering the fact that acute mental disturbances such as delirium tremens and psychoses induced with lysergic acid diethylamide (LSD) respond within hours to azacyclonol therapy, it seems logical to postulate that chronic mental disturbances would require a longer term of therapy and perhaps higher dosages. Further research along these lines as well as biochemical and physiological studies will be required to define the exact role of azacyclonol in our therapeutic armamentarium, but it is my opinion that it has a place.

Summary

A double-blind, controlled study was conducted with 171 chronic schizophrenic patients to determine the effect of azacyclonol (Frenquel) hydrochloride in terms of changes in delusions, ideas of reference, hallucinations, and behavior. Analysis of the data obtained *shows that azacyclonol has a statistically* significant effect (p=0.0003) in causing the disappearance of hallucinations and the lessening or disappearance of delusions, ideas of reference, assaultiveness, agitation, and seclusiveness. The data also suggest that improvement in relation to azacyclonol therapy is a function of the duration of therapy.

The other members of the research team that conducted this study were ward psychiatrists Eloise B. Peterson, M.D., Anna L. Smith, M.D., and Olga Steinicke, M.D.; a pharmacist; and four nurse supervisors.

CERVICAL RIB AND THROMBOSIS OF THE SUBCLAVIAN ARTERY

Henry A. Shenkin, M.D., Philadelphia

Three patients suffered a subclavian arterial thrombosis as a complication of a mild cervical rib syndrome. All three patients had had only mild symptoms for several years preceding the thrombosis. The thrombosis occurred without premonitory increase in symptoms. Surgical intervention should be advised as a prophylactic as well as therapeutic measure whenever a cervical rib produces even mild symptoms and arterial compression in some position can be demonstrated.

Thrombosis of the subclavian artery as the result of cervical rib compression, in most reported instances, leads to at least some degree of permanent disability in the involved extremity. Schein, Haimovici, and Young[1] could find only 30 reported cases in the literature, and, of these patients, 11 suffered a loss of a phalanx, 2 required a major upper extremity amputation, and 3 suffered a hemiplegia from extension of the thrombosis into the common carotid artery. They further reported that onset of subclavian thrombosis is most frequently abrupt, often following a single, apparently minor trauma to the vessel occasioned by

---

From the Albert Einstein Medical Center and Graduate Hospital.

strenuous activity. Despite this, conservative treatment of a cervical rib syndrome is generally recommended when symptoms are mild.[2]

Recent experiences with three patients who suffered a subclavian arterial thrombosis complicating a mild cervical rib syndrome suggest that indications for surgical decompression of the subclavian artery in the presence of a cervical rib should be broadened. All three patients had mild symptoms, noted over a period of years, and all appeared to be doing well on the conservative advice of competent specialists.

Report of Cases

Case 1.—On Oct. 21, 1953, a 47-year-old, right-handed toolmaker was admitted to the Graduate Hospital. In 1950, while carrying a cot over his head, he had noticed a tingling pain in his right arm that lasted for only a minute or two and caused the arm to be weak. Eight months later, while polishing the roof of his car, his right arm became so sore and weak that he had to stop. He consulted a physician and then a surgeon and he was told he had an extra rib but that, since his symptoms were relatively mild, conservative treatment was recommended. He was instructed to sleep with pillows beneath his shoulders and not to raise his arms over his head.

For four months prior to admission to the hospital the patient had noticed tingling and weakness of the right forearm. In addition the fingers of the right hand were seen to blanch whenever exposed to cold. There were no symptoms except when the extremity was used, but he was unable to continue on his job.

Examination revealed no arterial pulsations in the right upper extremity. The blood pressure in the left upper extremity was 140/60 mm. Hg. The right forearm and hand were cooler than the left. Bony hard masses were present in the inferior aspect of the supraclavicular triangle bilaterally. Arterial pulsations were palpable superficial to these masses.

On the day after admission the patient was seen by Dr. Samuel Lisker, who confirmed the above findings and further noted the absence of oscillometric readings in the right arm or forearm. Dr. Lisker performed a right stellate ganglion block, which resulted in immediate increase of warmth in the right upper extremity. The diagnosis was made of subclavian artery thrombosis due to compression caused by a cervical rib. Exploration and decompression of the vessel was recommended. If restoration of circulation through the subclavian artery could not be accomplished, Dr. Lisker recommended upper thoracic sympathectomy to aid the collateral circulation. X-ray examination of the chest revealed bilateral complete seventh cervical ribs.

On Oct. 28, 1953, the patient was operated upon, and pulsations in the subclavian artery were seen to stop under the scalene muscle. The muscle was sectioned, the artery was opened, and a firm thrombus was removed. A good flow of blood resulted from both proximal and distal portions of the artery. Upon repair of the artery good pulsations were noted in the subclavian and axillary vessels. Despite this, no pulsations were palpated below this level. An upper thoracic sympathectomy including the stellate, second, and third thoracic ganglions was performed. There appeared to be considerable improvement in the circulation of the extremity after sympathectomy, and after several weeks the patient was able to return to his former occupation. Three years after operation his improvement was maintained, and, although no pulse could be palpated below the axillary artery, the hand had good color and was just a trifle cooler than the left. The strength of the right hand grip was not quite as good as that of the left.

Case 2.—A 68-year-old man was admitted to the Albert Einstein Medical Center on Sept. 4, 1956. He had noted pain and discomfort in his right shoulder for the first time 12 years previously and had consulted an outstanding orthopedist, who discovered bilateral cervical ribs; the patient was told h symptoms were due to this anomaly. It was noted at that t that abduction of the arm would obliterate the radial pul A set of exercises was prescribed and, except for occasional d comfort in his arm, no difficulties were encountered over th course of the next 12 years until May 1, 1956. While touri Europe by car (with the patient as the driver), he noted col ness of the two small fingers of his right hand. A physician wa consulted in Genoa, Italy, and apparently at that time pul and blood pressure were obtainable in the right upper extre ity. About July 1 he noted weakness of the right hand, and h handwriting had deteriorated. Several weeks later another ph sician in Paris noted the pulses were absent in the right upp extremity, and the patient flew back to the United States. I early August, he noted considerable pain in his right hand an starting Aug. 15, a series of stellate blocks were performe From this point on, the pain was relieved and the color a warmth and strength of the right hand improved. This improv ment was maintained until the time of admission to the hospita even though the last stellate injection had been done two wee previously.

On Sept. 8, Dr. Benjamin Greenspan explored the right br chial and subclavian artery. A 6-in. incision was made on t medial aspect of the right upper arm. The brachial arter w found to be thrombosed through its entire extent. An incisi was then made in the supraclavicular triangle, and the scale muscle was sectioned at its insertion. The subclavian arte was found to be entirely thrombosed almost to the origin of t vertebral artery. I then removed the stellate, second, and thi thoracic sympathetic ganglions.

The patient made an uneventful recovery and was discharg from the hospital on Sept. 17, 1956. When last seen, t months after operation, he had maintained his improveme though the hand grip was still weak and the right hand w cooler than the left. Nevertheless, the hand had good color.

Case 3.—A 54-year-old female was admitted to the Albe Einstein Medical Center on Sept. 30, 1956, with a histor having had a sore throat and fever of 103 F (39.4 C) for hours. She also complained of slight indigestion. Examinati revealed a mild pharyngeal inflammation. She was known have had a mild hypertension, and at the time of her admi sion her blood pressure was 160/100 mm. Hg. Her hemoglob level was 15.1 Gm., and the white blood cell count was 4,2 per cubic millimeter, with 56% polymorphonuclear cells, 34 lymphocytes, 9% monocytes, and 1% basophils. On Oct. 1 h temperature was normal, but the next day her temperature we up to 102 F (38.9 C) and remained at that level on the follo ing day. From then on, her temperature was within norm limits. It was believed the patient had a viral infection, a infectious mononucleosis or an oncoming hepatitis was su pected. However, no lymph nodes were palpable nor was th liver.

On Oct. 5, sudden coldness, pain, and numbness in her right arm was noted at 1:30 p. m. It was now recalled that she had bilateral cervical ribs and that, as a matter of fact, on Sept. 25 1947, she had consulted an eminent surgeon because of shoulder and arm symptoms. He noted in his letter that "the swelling in the neck on the right side is due entirely to cervical rib and the soft tissue structures which have been pushed forward by i giving the sensation of a soft tissue mass. The subclavian artery gives a forceful pulsation in this area because it also has been pushed forward by the abnormally placed rib. Her pulse can be obliterated more easily than normal by abduction of the arm." It was his opinion that the arm symptoms were due to the pressure of the cervical rib, but, "because these symptoms were not severe enough, I did not advise her to be operated on, but told her that if the pain became severe enough to warrant operation she should seriously consider excision of the rib." Over the intervening years, she had occasional numbness in her hand and occasional pain but was never in serious difficulty, despite the fact that she was an ardent golfer and played frequently.

At the time of the onset of her difficulties on Oct. 5, 1956, symptoms appeared to start when she was combing her hair. amination at that time by Dr. Meyer Naide revealed that the ht hand was cold up to the wrist and there were no pulses in right arm below the subclavian artery. A prominent cervical was felt on the right side. Oscillations were absent in the ht upper arm and blood pressure was not obtainable in the ht arm. Blood pressure in the left arm was 140/90 mm. Hg. e right hand blanched rapidly in elevation and flushed slowly dependency. It was the impression of Dr. Naide that there s a thrombosis of the distal part of the subclavian or axillary ery resulting from injury to the artery by the cervical rib. recommended immediate stellate ganglion blocks and opera- n in an effort to remove the thrombus and also to excise the vical rib. Shortly thereafter, a right stellate ganglion block s done with improvement in the circulation of the limb and ne warming of the hand. It was agreed the operation should deferred, since she now appeared to be having adequate llateral circulation and she would be in better physical condi- n to withstand operation if the systemic infection could be t further behind her. Therefore, heparin therapy was started ravenously.

On Oct. 6 Dr. Naide noted that the circulation in the hand med to be better and that the color changes in the arm on vation and on dependency showed more rapid filling of the nd with blood. On Oct. 7, the right wrist and hand seemed oler than the previous day and it was decided that she ould be explored. At 6 p. m. the supraclavicular pulse, which s very prominent up until this time, suddenly ceased. At 7 m. the patient was operated upon by Dr. Alex Ulin. A sum- mary of his operative note is as follows: "The scalene muscle as sectioned and the subclavian artery was noted to have pul- tion only in its portion proximal to where it had been crossed the scalene muscle. When the scalene muscle was cut, the bclavian artery popped up. An arteriotomy was done and a esh thrombus was sucked out. The artery was irrigated prox- mally and distally with solution of Heparin and saline. The achial artery was then exposed by a small incision in the pper arm. Since this was thin and pulseless, the axillary artery as exposed by a vertical incision in the axilla. The insertions the pectoralis major and minor muscles were divided to expose e entire axillary artery. Axillary and brachial arteriotomies ere done with removal of clot as well as emboli located at the igin of the subscapularis artery. The back flow of blood was irly good. The vessel was irrigated distally and proximally ith Heparin solution and 2 cc.'s of Priscoline were injected nto the artery distally. Although the blood flow was now good, here was still only a poor pulse in the distal axillary artery. However, both the axillary and brachial wounds now bled reely for the first time. At this point, Dr. Shenkin removed the tellate and second and third thoracic sympathetic ganglia. The xillary artery was then reopened and more clot was removed nd it was irrigated again with Heparin solution. This time a ood proximal and distal blood flow was noted, although the pulse of the brachial artery was still weak. The wounds were hen irrigated with saline, the divided pectoralis muscles were utured and the wounds were all closed."

In the first few hours after operation, the right brachial pulse was barely palpable. No radial pulse could be palpated at any time. The patient was started on intramuscular heparin therapy eight hours after operation. The next morning the right hand was cool, and no radial pulse was palpable. The patient had some pain in her right hand, which felt warmer than it had been before, and there was a brachial pulse thought to be present just above the right elbow. On Oct. 14 the right hand was noted to be cooler than the left, but blood flow seemed adequate and the patient moved fingers and hand well; no pulse in the brachial or subclavian vessels could be felt. On Oct. 20 Dr. Naide stated that the veins in the right hand filled more rapidly than before and the hand was warm down to the fingers. The latter were only slightly cooler than the fingers of the left hand. On Oct. 23, 1956, she was discharged from the hospital with a note that she was much more comfortable than she had been and that strength was returning progressively to her hand. By February, 1957, full power and use had returned to the right upper extremity.

Comment

The three patients reported all had bilateral complete seventh cervical ribs and they were all right-handed, and it was the right extremity that was involved in each instance. Subclavian artery thrombosis in all but one previously reported case was associated with a complete cervical rib and in the majority of instances was right-sided, but complete information as to relationship of thrombosis to handedness is not available.[1]

All three patients were active people; the woman, a housewife, was also a frequent golfer. However, no single trauma could be related to the onset of thrombosis in either of the male patients. The third patient, the female in the series, when in a presumably debilitated state due to an acute infection, noted onset of symptoms of thrombosis when her arms were extended over her head while she was combing her hair.

Cervical rib symptoms were noted 3, 7, and 12 years prior to thrombosis in these three cases. The original, acute symptoms were short-lived, and all subsequent symptoms were mild. In all three patients compression of the subclavian vessel could be produced by hyperabducting or hyperextending the arm at the shoulder at the time of original examination years prior to thrombosis. Nevertheless, they all did well in the intervening years and had only minor, short-lived complaints that were never truly incapacitating as far as their chief interests were concerned. However, since thrombosis can occur so insidiously, one can hardly recommend, in retrospect, that these patients be observed for an increase in symptoms before considering decompression of the subclavian vessel. This is especially true because elective operation to decompress the subclavian artery and/or the brachial plexus is not at all a formidable procedure. It requires the section of the anterior scalene muscle and often the removal of a portion of the cervical rib. The extent of the procedure employed is dictated by the anatomic relationships encountered at the time of operation.

Some believe that the cervical rib should be removed in every case, feeling this would be most certain to relieve compression upon the subclavian artery and brachial plexus.[3] On the other hand, Adson[4] and others[5] pointed out that the scalene muscle is the structure against which the artery and plexus are compressed and that in most instances section of this muscle is all that is required unless the abnormal rib is exerting pressure on the brachial plexus from behind. The advantage of Adson's suggestion is that surgical trauma is minimized. Under any circumstance the brachial plexus must be handled with great care and as little as possible. Failing this, postoperative plexus pain can be troublesome for weeks or even months. Removal of the clavicle, as has been recommended,[6] has never been necessary in my experience, but should it appear to be desirable to do so after scalenotomy and cervical costectomy, it still should not add any real difficulty or danger to the procedure.

We did not feel it was necessary prophylactically to decompress the subclavian artery on the side opposite the thrombosed vessel in these patients, despite the presence of bilateral cervical ribs. They at no time had symptoms referrable to the nonoperated side, and compression of the subclavian artery could not be demonstrated in any position in which the arm was placed or head rotated upon the neck.

Once thrombosis occurred in these three patients, interruption of the sympathetic nerve supply to the extremity appeared to be of benefit. No restoration of blood flow below the subclavian vessel was accomplished in any case, and in each patient clear improvement followed interruption of the sympathetics. In the first patient stellate block with procaine hydrochloride (Novocain) was performed four months after thrombosis had occurred and was transiently but markedly effective in aiding the circulation. Steady improvement with sufficient recovery of power in the hand for the patient to return to his job occurred following sympathectomy. In the second patient, the onset of improvement dated from repeated stellate ganglion blocks first done two months after thrombosis. This seemed to have a permanent effect, since improvement was maintained for the two-week interval between his last stellate block and surgical sympathectomy. Whether further improvement resulted from the surgical sympathectomy could not be clearly determined. It would appear from the third patient's course that her improvement occurred more promptly, in a matter of weeks rather than months as in the first two patients. Perhaps this can be attributed to more prompt elimination of sympathetic tone, since the surgical attack on the thrombosed vessel itself appears to have been no more successful in this individual than in the other two.

The value of attack upon the vascular obstruction itself was certainly not clear in these patients. Despite valiant efforts, short of inserting a vascular graft, palpable pulses were not restored to the large vessels of the involved extremity. Schein, Haimovici, and Young [1] did insert a graft in two patients, but despite this pulsations distal to the subclavian artery were not restored, and from the description of their results there is nothing to choose between the postoperative status of their patients and ours. On this point, I have on two occasions ligated the subclavian artery in the course of performing an upper thoracic sympathectomy through an anterior approach without undue sequelae. (Both patients were young men, aged 21 and 29. The former had a causalgia due to a gunshot wound of the median nerve; the latter had a scalene syndrome without evidence of a cervical rib. In this second patient, the unintended sympathectomy was performed immediately after the vessel had to be ligated to control bleeding.)

Indeed, one may now suggest that the immed sympathectomy in these patients prevented the res ual symptoms noted in patients with spontane occlusion of the subclavian artery due to cervical r pressure reported above and previously in the lite ture. Since occlusion of the subclavian vessel occurs those instances in patients with presumably otherw normal vasculature, one may wonder if restoration the main stream of blood flow is necessary, since su cient collateral circulation should be available if ref vasospasm can be controlled. The operation for sy pathectomy can be completed in a relatively sh time, with little trauma to the patient. Efforts to r move thromboses or insert a graft are frequently ti consuming, require much more extensive surgical e posures, and perhaps in some instances could actual threaten the collateral vessels.

Summary

Three patients had subclavian artery thrombos associated with cervical ribs. Each patient had h mild symptoms for several years preceding throm bosis. Despite the fact the diagnosis of cervical r syndrome with arterial compression in certain pos tions was made, conservative treatment had bee advised. Thrombosis occurred without premonitor increase in symptoms. Surgical intervention should b advised as a prophylactic as well as therapeuti measure whenever a cervical rib produces even mil symptoms and arterial compression in some positio can be demonstrated. Interruption of the sympatheti innervation to the upper extremity after thrombos had occurred was clearly beneficial in this series o patients.

THE DELINQUENT CHILD AND THE FAMILY DOCTOR

Harry R. Brickman, M.D., Los Angeles

The young child cannot be expected to recognize pernicious factors in his environment, much less to correct them. Delinquent behavior is the resultant of such factors and requires treatment rather than punishment. The development of humane treatment orientation in our correctional systems is hindered by the hue and cry of the community for punishment. The family physician sees that delinquency is as much a manifestation of personal pathology as epilepsy or syphilis. He can recognize the intrafamilial tensions, especially the unconscious assignment of roles to children by parents, that lead to antisocial behavior. He can advise, correct, and treat. He can convey his orientation to others. As a counselor to the family and at the same time an influential citizen, he can help to develop a community attitude less interested in punishment and more desirous of correcting the causes of delinquency.

The delinquent child is a sick child. As a sick child he requires treatment rather than punishment. This paper attempts to demonstrate that the physician who understands a few basic principles of the family origins of delinquent behavior may serve as a vital agent of prevention and treatment of this form of pathology.

Because the delinquent is offensive to society and to its laws, the legal profession and its offshoots have been assigned the role of dealing with this type of illness. Juvenile police agencies, probation departments, courts, and correctional agencies have all traditionally been managed under a legalistic philosophy. In recent years, however, workers from professions with treatment philosophies have come to deal more and more with delinquent children and adults. This is particularly true of the profession of social work. In ever-increasing numbers, punishment-oriented personnel are being supplanted by social workers who see the delinquent as ill and who are interested in treating him. These professional workers are approaching, with a sense of adventure, the difficulties of actually achieving treatment in this field. For, although a therapeutic attitude toward the delinquent is essential, it is also important for treatment to be firm, authoritative, and controlling if and when it is necessary.

The medical profession, too, is becoming increasingly interested in the problem of delinquency.[1] Psychoanalytic psychiatry, particularly, has evolved some interesting concepts and findings which hold promise for treatment efforts with this type of illness. These findings are suggesting areas in which the family doctor can play an important role in the prevention and treatment of delinquent behavior in childhood.

A prerequisite to assuming an effective treatment role is an understanding of disturbed family relationships and their effect on childhood behavior. For purposes of this discussion, the so-called sociological delinquent will not be considered. The concept of the "normal" delinquent whose behavior is said to reflect socioeconomic tensions exclusive of personal psychopathology is highly controversial. After all, a delinquent act or two does not define a delinquent. Rather, the true delinquent is one who follows a pattern of repetitive antisocial behavior. This pattern is defined for the delinquent child by parental figures through a process which might be called unconscious role assignment.

Some Principles of "Unconscious Role Assignment"

One of the most far-reaching findings of intensive psychoanalytic investigation of delinquency is the concept of the unconscious sanctioning of delinquent behavior in the child by the parent. Johnson and Szurek[2] have emphasized that antisocial behavior in children almost invariably proceeds from this type of unwitting parental permission. These findings have been confirmed by me in my work with delinquent children[3] and by others in the field.[4]

Careful clinical study of the families of delinquent children has unearthed many ways in which parents, struggling with their own emotional problems and against their own antisocial impulses, unwittingly and unconsciously evoke, provoke, and even encourage delinquent behavior in certain of their children. A parent may relive in one of his children certain poorly resolved conflicts from his own childhood.

> A father, telling the psychiatrist about his son Tommy's many misdeeds in the classroom, used stern words. The smile on his face, however, was most eloquent and gave away his real attitude toward the child's behavior. It denoted the vicarious satisfaction which he, the father, a poliomyelitis cripple since the age of 3 years, enjoyed from Tom's social misbehavior. He said, smiling, "That boy of mine can sure stir up a lot of hell."

A parent may select one child as a scapegoat for feelings displaced from another person and may, by unwitting remarks, thereby assign to the child a

"delinquent role" just as surely as if he had deliberately dressed the child in a striped prison suit from early infancy.

Joe, a 26-year-old heroin addict and petty larcenist, seemed more than a little puzzled when speaking of his mother. She always seemed to stick by him in times of trouble. She had not missed a court trial or a prison visit to him for years. She *did not* seem angry with him, really—but perhaps resigned. Yes, that was it—from early childhood, mother would sigh at his misdeeds, referring to things called "bad blood," "black sheep," and other similar designations. Also, she constantly reminded him that he was "just like his father," a man who himself had been in and out of jail on innumerable occasions, was severely alcoholic, and had not lived in the home since Joe's mother had divorced him when the child was 3 years of age.

These phenomena are not limited to broken homes. The highly influential and powerful captain of industry may unwittingly contribute to the lifelong delinquent resignation of a child who is struggling mightily but ineffectively to follow in his footsteps.

Sixteen-year-old John Jr. was charged with attempted rape of a 6-year-old girl. His father, a wealthy real estate developer and financier, was shocked and bewildered at the news. As John Sr. put it, "I've given the boy everything he has ever needed; we've sent him to the finest boarding schools in the East." John Jr. was an effeminate, mildly depressed, inadequate boy whose father was "too busy" to give him what he really needed, the companionship and opportunity for warm identification which fosters the development of personal identity. John Sr. was inaccessible and unattainable to his son, who turned in his relationship-hunger to his mother. She, also frustrated and lonely, sought relief by immersing herself in social activities and engaging in occasional amorous adventures with door-to-door salesmen.

There are many additional factors in parent-child relationships which may contribute to the child's assumption of the delinquent role. These factors are found when one examines the attitudinal climate in which children are raised. One such factor is seen in the family in which a double standard of truthfulness—for child and for adult—exists. The mother who extols truthfulness at the dinner table but instructs the child to misrepresent his age at a movie or in a public vehicle to avoid paying full tariff is making such a contribution. Also, families in which a given child is the open favorite may provoke attitudes of insecurity and rebellion in one or more of the siblings.

Interestingly enough, families in which angry or rebellious behavior is consistently and strictly interdicted may still produce their delinquents. One sees at least two types of such delinquents. One might be the minister's son or daughter who commits a violent crime, such as murder, in an emotional crisis. This child is often found to have developed no mechanisms for expressing the minor hostilities and rebellions of everyday life in the face of a family passion for "positive thinking." Another type is the child suffering from the "baby thrown out with the bath water" syndrome, in which it is constantly communicated by the parent that the child himself is bad, naughty, and worthless, along with his unacceptable behavior. This becomes a cue for building identity—and a child would rather build a negative identity than none at all.

Unconscious role assignment can be seen as a common factor in all these phenomena of family conflict. By this process, characteristic personality patterns are developed in the individual through the unconsciously communicated assignment of roles by the powerful human figures—the parents—in the child's environment.

Role assignment and role assumption in the family are facilitated by two potent valences in the parent-child relationship. On the child's part, it is an all-pervading need to be loved by the parent and to meet any conditions imposed by the parent which may be necessary to gain that love. On the parent's part, it is a tendency to see significant people, including offspring, in definite roles rather than as individuals in their own right. An attempt is made to unconsciously assign roles, so that the neurotic parent may order, or construct, his human environment so as to either gratify or deny certain particular emotional needs. An example of such needs might be the tendency to relive emotionally charged childhood experiences in one's own children. The parent may unwittingly assign the delinquent role to a child in his attempt to "give my child the freedom I didn't get." Or, the more deeply hidden determination that "the child will suffer just as I had to suffer" may lead to such a role assignment.

The child's need for parental love causes him to constantly seek cues for his behavior, to be "clued in" as to his identity. Thus, he becomes the passive recipient of the role to which he is unconsciously assigned by the parent. Even if the child must assume the role of a "bad child," this may gain him a type of recognition from the parent which may be a poor, but nevertheless valuable, alternative to rejection and its consequent feeling of dread.

Perhaps parental mental health may be measured according to the willingness of the parent to allow the child to develop his own identity. We might then say that the emotionally sound parent reacts to his child as an individual human being with certain constitutional attributes, certain strengths to be supported, and certain human weaknesses which the child should be helped to control. The unconscious tendency of the parent to assign to the child a certain role reflecting the parent's own emotional problems can be seen, then, as a type of molding of the child into an image which suits the parent's neurotic drives but which does violence to the child's full emotional growth, sense of healthy identity, and general self-esteem.

Erikson[5] has evolved an interesting and valuable concept of the life-task of adolescence. He has pictured the normal adolescent period as a time during which a "psychosocial moratorium" is provided for the child in order for him to experiment freely with various possible personal and social roles. Presumably, a healthy choice of role—personal, social, occupational, and sexual—is the outcome of this freedom to experiment and ideally culminates in a role and identity assumption which reflects the child's individuality. An absence or foreclosure of this moratorium might lead to "identity diffusion"—a psychopathological state often manifested by delinquent behavior.

It may be postulated that teen-agers suffering from identity diffusion and delinquent behavior may, in most cases, be experiencing the result of role fixation, resulting from the premature precipitation of a neurotic or delinquent role through the process of unconscious role assignment. In such cases, the absence or foreclosure of the psychosocial moratorium may result from the same neurotic parental drives which originally produced the childhood role assignment. Even in the unlikely event of the creation of a true moratorium for such a child, however, it is doubtful that his fixated delinquent role can dissolve from this process alone. Some type of psychotherapeutic experience would be judged necessary to achieve such a change of role.

The phenomenon of unconscious role assignment may well be involved in the case of every neurotic child. Further basic research and clinical investigation are needed to delineate the nature of the specific emotional conflicts of the parents which lead to the specific unconscious role assumptions in the neurotic child. In the case of the delinquent child, it is postulated that personality difficulties in one or both parents with particular regard to antisocial impulses are combined with hostile-aggressive coloring of intrafamilial relationships—especially the child-parent relationship—to produce a phenomenon which might be considered unconscious assignment of the delinquent role. This, then, is the hidden agenda of parent-child communication.

Role of Family Doctor

The foregoing material would suggest that the general practitioner or pediatrician may serve an important role in prevention and treatment of delinquency as a symptom of the family in emotional trouble. It would almost be superfluous to point out, for instance, that knowledge by the family doctor of the hidden agenda of intrafamilial communication, the particular patterns of unconscious role assignment, and other aspects of the family neurosis will help him to serve in his time-honored advisory function much more efficiently. The old-fashioned family doctor intuitively perceived these phenomena and was guided accordingly in his relationship to the family. The prevalence of these powerful forces is, from a preventive psychiatrist's point of view, one of the most potent arguments for the renewed encouragement of family medicine. With his knowledge of the specifics of unconscious role assignment in a particular family, psychotherapeutic measures may be undertaken by the physician. These have been outlined elsewhere[6] and will not be elaborated in any detail in this paper.

In many cases, specific directive counseling of the parents by the family doctor who is aware of these factors may be sufficient. In selected cases, the family physician who has had training and experience in office psychotherapy may consider undertaking brief psychotherapeutic work with one or both parents with the aim of yielding some insight into how their own emotional problems affect the problem child's behavior pattern. In other cases, serious emotional disturbance in the parents or in the child may necessitate referral to the psychiatrist. In these instances, the family doctor can make an important contribution to treatment if he devotes some time and effort to preparing the family for the psychiatric referral. By providing reassurance and otherwise overcoming resistances that so often occur when a psychiatric referral is contemplated, motivation for psychotherapy by the specialist is increased and his work is thus enhanced.

Aside from general supportive psychotherapeutic measures which may be effectively carried out when the vicissitudes of the family neurosis are understood by the physician, the doctor-patient relationship itself may have an important bearing on the family doctor's management of the delinquent child. The relationship of the family physician to his patient, whether the patient be parent or child, is one of the most powerful existing vehicles for human interaction. The family doctor, in relating to members of the family, may be kind, permissive, and firm, or he may act the role of the tyrannical parent.

Depending on his own role, a type of unconscious role assignment may take place with regard to his patients. This phenomenon may possibly explain the apparent differences in caseload between different doctors. One family doctor may end his day tired but pleased, generally satisfied with his sick but largely cooperative patients. Another family doctor may end his day in a mood of vexed irritability, clucking his tongue over his stubborn, uncooperative, "bad" patients. The latter, in his role of the prohibiting parent, may punitively reject his patients for failure to carry out instructions, and thus may unconsciously assign them an uncooperative role. Other family doctors may practice a double standard of truth—expecting the patient to tell the doctor everything but pursuing their work behind a veil of magic secrecy, even when there are no obvious contraindications to keeping the patient entirely informed.

The family doctor who manages to avoid unconscious role assignment in his relationships with his patients may set a certain example to parents. The physician often functions as a type of parental figure for the adult members of the family, a strong authority figure with power over life and death. Perhaps the manner in which the family doctor acquits his role as authoritative parental figure may have some communication value to families in which unhealthy unconscious role assignments are taking place. The family doctor also acts to advise parents on eating habits, bowel training, and childhood behavior problems. A knowledge of the contribution of family conflict to the developmental and emotional problems of children can be a priceless asset in helping the family.

The Family Doctor and the Punishing Community

A further constructive approach to the delinquent child and his unfortunate heir, the criminal adult, may be through the family doctor's capacity as a citizen—usually a highly respected and influential citizen. Communities tend to perpetuate the unconscious role assignments which antisocial individuals have assumed. One of the greatest deterrents to the development of a humane treatment orientation in our correctional systems has been the hue and cry of the community for punishment. If the family doctor, convinced that delinquency is as much a manifestation of personal pathology as epilepsy or syphilis, can convey his orientation to others, the same type of community progress with regard to delinquency as has occurred with regard to these other two socially stigmatized illnesses may ensue. Thus a more treatment-minded public, less interested in punishment and more desirous of understanding delinquency, may be developed.

Summary

The delinquent child is being increasingly approached with a treatment attitude, as contrasted with punishment. The family doctor is in a position to perceive the intrafamilial tensions which produce, largely through unconscious role assignment, delinquent behavior in children. As trusted advisor and counselor to the family, he may influence these factors through psychotherapeutic maneuvers, through carefully prepared psychiatric referral, and through awareness of the strong effects of the doctor-patient relationship. As an important and influential citizen, the family doctor may contribute to community movement away from punishment and toward understanding and treatment of the delinquent child and adult.

Air-borne Infections.—Much effort has been expended in attempt to control air-borne transmission. Important fundamental facts have been gained, particularly in respect to particle size. Air-borne spread of numerous mycotic infections has general acceptance. Notably more weight is given that mode in tuberculosis. It has an established place in Q fever and psittacosis. However, initial enthusiasm in respect to common respiratory infections was stretched beyond reasonable limits, with inevitable reaction. The inability to devise practical methods for their control through attack on dust or droplet nuclei, although numbers of agents in the air could often be reduced, has resulted in diminishing enthusiasm about the general problem. Present day opinion supports that of Chapin expressed so many years ago, that spread by contact is the dominant consideration in the common respiratory diseases. If that is correct the observation holds still more for other kinds of infection. But that is opinion, and quantitation is necessary, which marks the need for continuing studies. Too little is known of the variations from disease to disease and of the circumstances of exposure which determine significance in air-borne spread. The combined approach of clinic, laboratory and field study now gives method not available in 1935. There is need to work for better control methods, an obligation to define what is to be controlled, to add to understanding of pathogenesis, and to evaluate air-borne spread under the conditions inevitably to come with a changing world of infectious disease.—J. E. Gordon, M.D., and T. H. Ingalls, M.D., Preventive Medicine and Epidemiology—Contact and Air-borne Transmission of Infectious Agents, *The American Journal of the Medical Sciences*, March, 1957.

THE MISSION OF PREVENTIVE MEDICINE

Brig. Gen. Edward J. Tracy (MC), U. S. A. F.

The specialist in public health must not be content to confine his interests to disease rate factors but must concern himself with the tremendous impact of an industrial environment on our entire population, almost half of which is employed. The techniques of studying environmental hazards have had rather extensive use in industry and have also been used to advantage in public health problems such as atmospheric and water pollution and new food additives. In addition, however, the public health specialist must recognize the need for studying the means of lowering mortality and morbidity from accidents in the home and on the highway. Problems of electromagnetic radiation, noise, and other physical health hazards promise to become increasingly important community problems.

It is of utmost importance that the medical profession recognize its mission in the field of preventive medicine today and in the future. We are in the midst of an unprecedented age of technical progress; we are surrounded by the end-products, intermediates, and by-products of our own industry. Furthermore, we are placing more and more of our population in an industrial environment, both at work and at home. The literature is full of references to the impact that these technical developments are having on the field of medicine—especially preventive medicine and its subspecialties.

The challenge has been presented to us to exercise sound medical judgment in helping to shape the future. Our creed must continue to be one of maximum service to mankind and our community. It is vital that we effectively utilize the relatively small number of medical personnel adequately trained in the field of preventive medicine. Such men must, for a time, act in the role of medical missionaries—educating medical students, fellow physicians, and others in the concepts of preventive medicine in our time.

Subspecialty-Barriers

The concentration of attention on the differences between subspecialties may cause us, if we are not wary, to lose sight of the over-all mission of preventive medicine. It is only natural for a man to take pride in his area of special knowledge, but he should not let such pride make him blind to the need for broad knowledge in the over-all field.

I would like to emphasize the need for crossing the subspecialty barriers whenever it appears that the over-all mission may be better served by so doing. For example, in the Air Force, it is obviously not practical to provide specialists in each preventive medicine subspecialty at every Air Force installation. There just would not be enough specialists to go around. Thus, the specialist in aviation medicine must be capable of supervising public health measures such as immunizations and epidemiologic investigations. He should also be capable of solving problems in occupational medicine (occurring in ground support crews as well as air crews) by use of industrial hygiene surveys, the environmental health laboratory, and other means of evaluating and controlling toxicity. After all, even the best pilot cannot get off the ground if the plane does not receive proper maintenance.

Examples of Cross Utilization

Commercial air transportation is being used more and more for industrial employees. Private aircraft are utilized in some companies, and there is an increasing need for the use of medical standards of aviation by the industrial physician. During the past three years, at Headquarters Air Matériel Command, we have conducted symposiums on aviation medicine for physicians in the Air Force residency training program. I am pleased to note that more and more interest and participation in these meetings is evident among our civilian colleagues in the field of occupational medicine as well as in the field of aviation medicine.

The increasing use of insecticides in aircraft as a means of controlling spread of insect vectors (or on the ground to control termites) has involved specialists in public health in problems of aviation medicine on the one hand and toxicology (from contamination of water supplies for human or animal consumption) on the other. The U. S. Public Health Service is providing occupational medicine coverage in a number of instances—e. g., cholinesterase determinations in workers in the fruit orchards in the state of Washington and studies on workers exposed to radioactivity in the process of mining uranium.

Certainly every industrial physician must be intimately concerned with the tremendous costs of noneffectiveness in the work force resulting from

---

Surgeon, Headquarters Air Matériel Command, Wright-Patterson Air Force Base, Dayton, Ohio.

Chairman's address, read before the Section on Preventive Medicine at the 106th Annual Meeting of the American Medical Association, New York, June 5, 1957.

nonoccupational communicable diseases and in the detection of health trends by statistical methods—basically epidemiologic considerations.

In general, we might state that the specialist in aviation medicine would benefit from greater familiarity with and utilization of certain personnel, techniques, and laboratories which the industrial physician uses to support day-to-day activities. It would help the flight surgeon maintain better control of health hazards affecting crew personnel who fly the aircraft as well as ground support personnel who get the plane ready to fly.

The specialist in public health must not be content to confine his interests to disease rate factors but must concern himself with the tremendous impact of an industrial environment on our entire population, almost half of which is employed. The techniques of studying environmental hazards have had rather extensive use in industry and have also been used to advantage in public health problems such as atmospheric and water pollution and new food additives. In addition, however, the public health specialist must recognize the need for studying the means of lowering mortality and morbidity from accidents in the home and on the highway. Problems of electromagnetic radiation, noise, and other physical health hazards promise to become increasingly important community problems. Much of the significant work in all of these fields has arisen out of specific occupational or aviation medical problems which have been studied in private industry and in the armed forces.

Maximum Utilization Necessary

I have attempted to view afresh the challenge which has been presented to the medical profession and related sciences by the nature of our technical industrial progress. It is incumbent upon us, as individuals and as a group, to accept this problem and to take steps towards its satisfactory resolution. Such steps must emphasize the maximum utilization of our existing personnel, techniques, and facilities rather than the creation of barriers within the preventive medicine specialty.

I believe that the action taken at the last annual meeting to change the name of the section from the Section on Preventive and Industrial Medicine and Public Health to simply the Section on Preventive Medicine indicates a very healthy trend. In addition, the rotation of the chair between the subspecialties can be used to broaden the concept of cross training in preventive medicine. I sincerely hope, for the sake of our country as well as our profession, that we in the preventive medicine specialty will accept the challenge thrust upon us. If we will recognize the problem in the fullness of its scope, I feel that we will have made a very important step toward its solution.

P. O. Box 102, Area "A," Wright-Patterson Air Force Base, Dayton, Ohio.

CLINICAL NOTES

VENOUS THROMBOSIS SIMULATING ARTERIAL EMBOLIZATION WITH MAJOR GANGRENE

John V. Waller, M.D., New York

That venous thrombosis may mimic acute arterial thrombosis or embolism and produce major gangrene of an extremity has been suggested by Edwards[1] and by Scupham.[2] The latter quotes Pringle[3] whose two cases, at pathological examination, showed post-traumatic venous thrombosis and patent arterial systems. Since the arterial spasm which produced the ischemia and gangrene may have been post-traumatic and not solely secondary to the venous thrombosis, specific illustration of the speculation of Edwards and Scupham was lacking. The following case illustrates the clinical and pathological occurrence of isolated venous thrombosis producing arterial spasm and major gangrene of an extremity without the slightest clinical suggestion of disease of the vein.

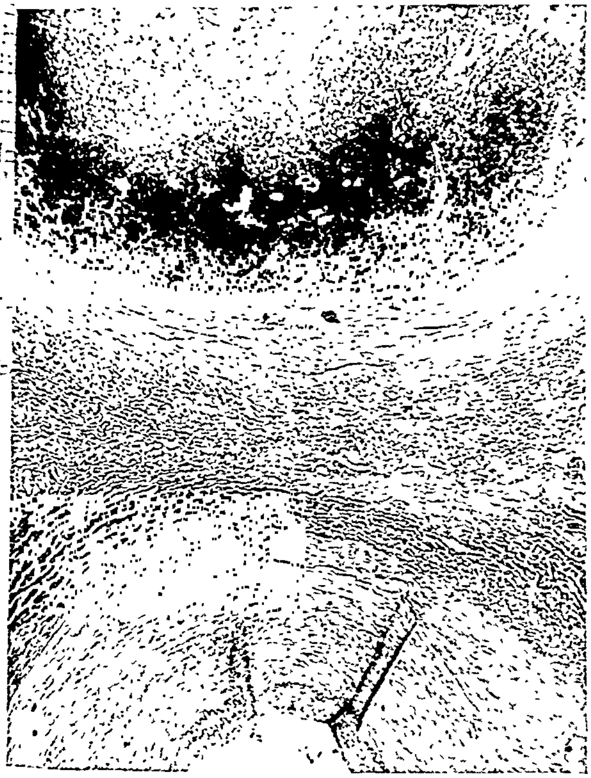
Report of a Case

A 60-year-old woman, in comma, was admitted to the hospital on Oct. 28, 1949. The patient had been in apparent good health until Oct. 21, when diabetes mellitus and atrial fibrillation were discovered by her family physician. She was placed on a restricted diet and on therapy with digitoxin. Several hours prior to admission, she could not be awakened from an afternoon nap. Physical examination at the hospital revealed semi-coma, complete aphasia, and but slight voluntary motion of the eyes, left arm, and left leg. The blood pressure was 140/70 mm. Hg. The heartbeat was totally irregular, with an apical rate of 68 beats per minute. Both dorsalis pedis arteries were palpable. The remainder of the physical examinations, except for neurological findings, was normal. The blood sugar level was 150 mg. per 100 cc. The electrocardiogram revealed atrial fibrillation and digitalis effect. The diagnoses were arteriosclerotic heart disease with atrial fibrillation, diabetes mellitus, embolization of the left middle cerebral artery, sensory and motor aphasia, and hemiplegia on the right.

From the Department of Medicine and the Vascular Clinic, Lenox Hill Hospital.

the ensuing 14 days the patient showed no signs of recov- On the morning of the 15th hospital day, the nurse, while orming the usual morning care, noticed that the right leg the knee down was cold. There was pallor, mottled with sh areas. Examination confirmed these findings. The limb cadaverous and cold. On elevation there was extreme pal- Only the femoral pulse was detectable on the right side. re was no petechiasis, edema, or venous congestion. The lower extremity was normal in all respects. Papaverine rochloride (65 mg.) was injected into the right femoral ry. This injection was followed by a right lumbar sympa- ic block with procaine hydrochloride (Novocain). There no change distal to the knee.

ecause of the patient's very poor general condition and ause of the irreversible changes in the right foot and leg, loration for possible embolectomy was not attempted. Dur- the course of the next 10 days, extensive dry gangrene of right foot and leg developed. At this time, a midthigh mputation was performed. The surgeon noted normal pulsa- ions of the femoral artery and moderate bleeding in spite of the use of the tourniquet. The patient died 10 days later. Autopsy was not performed.



Section showing femoral vein occluded by organizing throm- us and contiguous patent femoral artery at level of midthigh mputation.

Pathological examination of the amputated leg showed that the femoral vein had been sectioned at operation through a olid (see figure) thrombus. This thrombus extended to the unction of the femoral and popliteal veins. The popliteal vein was normal. The venae comitantes of the named arteries were dissected and found patent and normal. There was extensive gangrene of the foot and of the lateral and medial aspects of the leg below the knee. The entire arterial system was explored and found to be normal. Dissection was carried out from the point of amputation down to and including the dorsalis pedis and posterior tibial arteries.

Comment

Gangrene of part of an extremity from clinically evident massive thrombophlebitis is a rare, though well-known, occurrence.[4] This catastrophe may occur whether the peripheral arteries are pulsating or in spasm. In the former instance, the heart is merely pumping more blood into a circulatory tree from which there is no exit,[5] as all of the veins are occluded by the phlebitis. Venous thrombosis frequently gives rise to some degree of arterial spasm.[6] Whether this spasm is due to reflex through the sympathetic pathways,[7] perivenous inflammation affecting contiguous arteries,[8] vasoconstrictor substances released by the lysis of platelets,[9] to the local effect of serotonin,[10] or to a combination of these factors plus others as yet unknown is a matter for speculation. Lumbar sympathetic block and intra-arterial injection of tolazoline (Priscoline) hydrochloride or papaverine are usually effective in the release of arterial spasm,[8] but they were of no avail in the present case.

Kinmonth[11] found segmental traumatic arterial spasm completely resistant to sympathectomy, periarterial stripping, and intra-arterial medication. He discovered that exploration, followed by periarterial bathing with warm solutions of papaverine sulfate, was the only successful treatment. Perhaps arterial spasm secondary to venous thrombosis will respond to the same modality. Of course the cerebral vascular accident in this case prevented early discovery of the ischemia at which time the measures employed might have been of some help.

Gangrene of the leg was due to arterial spasm in the presence of unsuspected thrombosis of the femoral vein. Measures directed at relieving the arterial spasm were not effective.

TREATMENT OF ORAL HISTOPLASMOSIS BY LOCAL INJECTION WITH NYSTATI

Harold Plotnick, M.D.

and

Santo Cerri, M.D., Cincinnati

As yet, no specific therapy for histoplasmosis has been developed clinically. The effective inhibitory nature of nystatin on Histoplasma capsulatum has been demonstrated both in vitro and in animals experimentally infected.[1] On this premise, we injected nystatin solution directly into oral lesions of histoplasmosis and observed the gradual but complete disappearance of the localized disease process.

Report of a Case

A 78-year-old man was admitted to the Cincinnati General Hospital on Sept. 13, 1955, with the history of firm "blisters" that had been appearing in his mouth since mid-July, 1955. There were no other subjective complaints. On physical examination, this elderly man appeared thin but not ill. Examination of the oral cavity revealed multiple, firm, nontender, mucosa-covered nodules, which varied in size from 5 to 10 mm. in their greatest diameter. The lesions were distributed as follows: two nodules on the upper and one on the lower labial mucosa, one on the left buccal mucosa approximately 2 cm. lateral to the lip commissure (fig. 1*A*), and two on the middle of the left lateral border of the tongue (fig. 1*B*). The surfaces were smooth except for the buccal lesion, which had a superficial erosion but no bleeding points. Nasal, pharyngeal, and indirect laryngeal examination failed to reveal any abnormalities. The remainder of the physical examination was essentially negative.

The nodule from the lower labial surface was totally excised and submitted for histological studies. The pathologist's report stated: "There is a chronic inflammatory infiltrate in the submucosal region of the specimen with considerable histiocyte proliferation and giant cell formation. The histiocytes show histoplasmal organisms. The Hotchkiss-McManus stain for fungus confirmed the presence of the latter."

The histoplasmin (1:1,000) skin test was read as 2+ in 72 hours. The tuberculin test (first-strength purified protein derivative [PPD]) was 2+ in 48 hours. The blastomycin (1:1,000) and coccidioidin (1:1,000) skin tests were both negative. complement-fixation test for histoplasmosis was negative. Ro genograms of the chest and spleen showed no signs of dis The bone marrow studies revealed no evidence of orga on either smear or culture. The stool guaiac test was neg The hemogram and urine examinations were not remark Liver-function studies were within normal values.

Both lesions of the upper lip were completely excised, an tissue press was prepared and stained by the Giemsa meth The smear showed typical histoplasmal organisms both wit and outside of swollen macrophages (fig. 2). This tissue also submitted for mycological culture. The latter grew out H capsulatum organisms at room temperature in 10 days.

On Oct. 18, 1955, freshly prepared nystatin for intraven administration diluted in 5% glucose in water, representi 2,000 units per milliliter, was injected below and into the b cal lesion until a ballooning effect was noted. Three days la (Oct. 21), some regression in the size of the lesion was evid On Oct. 22, freshly prepared nystatin solution was again i jected in a similar fashion into both the buccal lesion and t nodules on the lateral edge of the tongue. Marked pain wa associated with the infiltration of the nystatin into the tong lesions. All treated lesions slowly regressed. No control type o injection was used. Nystatin was again injected into the thre nodules on Nov. 2, 1955. The patient was discharged from t hospital on Nov. 3. He was next seen in the dermatology o patient dispensary on Nov. 29, 1955. At that time, the lesi in all three treated areas were progressively smaller. The pa tient was seen on Dec. 14, 1955, and there were no signs o any disease process in the oral cavity. The patient was followe up at periodic monthly intervals after that, with no signs o recurrence (fig. 1*C* and *D*). He continually refused to all biopsy of the treated buccal area. The patient's case was pr sented before the Cincinnati Dermatological Society as a follo up study on May 2, 1956. There were no signs or symptom o oral histoplasmosis at this time; however, the patient relat that for the past month he had been losing weight and ha become weaker.

On May 14, 1956, he was readmitted to the Cincinnati Ge eral Hospital. Roentgenograms of the chest revealed a mottle infiltrate in the left upper lobe. Skin tests with histoplasmi (1:1,000) and first-strength PPD were both positive in 4 hours. Sputum studies were consistently positive for acid-fa

nisms. The patient was transferred to Dunham Tuberculosis oital on May 31. On June 14, 1956, the patient fell off a cher, went into a state of irreversible shock, and died. r. Black-Shaffer, of the department of pathology, summar- the postmortem examination as follows: "The gross autopsy ngs were those of pulmonary edema and miliary tuber- sis. Examination of the histologic preparations revealed a espread but not very progressive miliary tuberculosis in the gs. These took the form of isolated and small confluent tu- les, some with central caseation necrosis. The liver and en showed widespread epithelioid tubercle granulomas. In sections of the heart, there was a tubercle present in the atrium. Careful search for Histoplasma capsulatum was tless. Gridley stains, likewise, failed to reveal any recogniza- histoplasma bodies. The final diagnosis was only miliary erculosis."

Comment

Histoplasmosis, once an obscure fungous disease, being recognized with increasing frequency, espe- ially in the endemic areas comprising southern Illinois, ndiana, Iowa, Kansas, Kentucky, Missouri, Ohio, and ennessee. H. capsulatum has been repeatedly re- overed from soil. Primarily for this reason, the dis- ase seems to be most frequently acquired by inhala- on of spore-containing dust. It is not certain as to ow the organism actually enters the body and local- es in the skin or mucous membranes. Curtis and rekin[2] state that, for the purposes of classification, istoplasmosis may be divided into two categories, ccording to whether the portal of entry is (1) pri- ary in the skin and adjacent mucous membranes or 2) systemic, via the respiratory or gastrointestinal ystem, with the cutaneous or mucosal lesions that do occur due to secondary invasion. Silverman and coworkers[3] believe that the initial infection is in the lower respiratory tract and that dissemination can then take place to the skin and mucous membranes or to other organ systems. Silverman's group feels that, if the skin or mucous membranes were the primary site, regional lymph node involvement would be more often encountered.

Nodular, noduloulcerative, and vegetative lesions on the tongue, lips, buccal mucosa, hard and soft palate, larynx, or vocal cords are suggestive of histoplasmosis.[4] The tongue and larynx are most often involved by a granulomatous process, which frequently ulcerates.[5] The majority of such oral lesions occur in people over 40 years of age.[6]

One must consider carcinoma, syphilis, leishmaniasis, Vincent's infection, leukemia, and Hodgkin's disease as well as other granulomatous ulcerative diseases in the differential diagnosis of oral histoplasmosis.

Summary

A patient with proved oral histoplasmosis was treated by the local intralesional injection of nystatin. This was associated with complete disappearance of the treated areas. The patient later died, and the autopsy revealed miliary tuberculosis but no evidence of histoplasmosis.

AMMONIA CONTENT OF STORED BLOOD

Julius R. Greenberg, M.D., Leonard D. Rosenman, M.D.
and
Alvin E. Lewis, M.D., San Francisco

Numerous recent publications have attested the significance of elevations in the levels of ammonia in the circulating blood of patients with certain liver diseases.[1] Stuporous phenomena have been observed when the ammonia-nitrogen level of blood has exceeded 200 mcg. per 100 ml. The blood of a healthy person contains minute amounts of ammonia, which increase when blood stands in an open container exposed to room air.[2] In our laboratory, as in others, the ammonia level in the blood of a healthy person has been found not to exceed 50 mcg. per 100 ml.

Stupor, or coma, occurs not infrequently during or following episodes of esophageal or gastrointestinal hemorrhage in patients with liver disease when there is interference with the passage of portal venous blood through the liver. It generally is agreed that a prime source of the increased ammonia content of the blood is the extravasated blood acted upon by the intestinal secretions and bacteria. Since treatment of the hemorrhagic complications usually includes replacement transfusions, it has been suspected that stored blood, the usual source for transfusion, may contain toxic quantities of ammonia. Cincotti[3] observed a rise in the ammonia-nitrogen content of banked blood from a normal level of 9 mcg. per 100 ml. to 900 mcg. per 100 ml. during three weeks of storage.

A study of the formation of ammonia in decomposing blood in the San Francisco blood bank has been carried out in our laboratory. Sixteen pints of blood, collected and stored in the usual fashion, were sampled at intervals, 2 to 68 days after collection. The data are presented in the table and the figure.

The ammonia determinations in this study were all made in duplicate with the Conway microdiffusion method[2] being used. Using a 10-minute absorption interval, we have confirmed Conway's finding that a consistent proportion of the total is absorbed. Th in routine determinations the 10-minute interval w used with appropriate correction factors. A final c rection for temperature effect was made by subtracti (0.0054t–0.38) micrograms, with t being the centigra temperature. All determinations were controlled

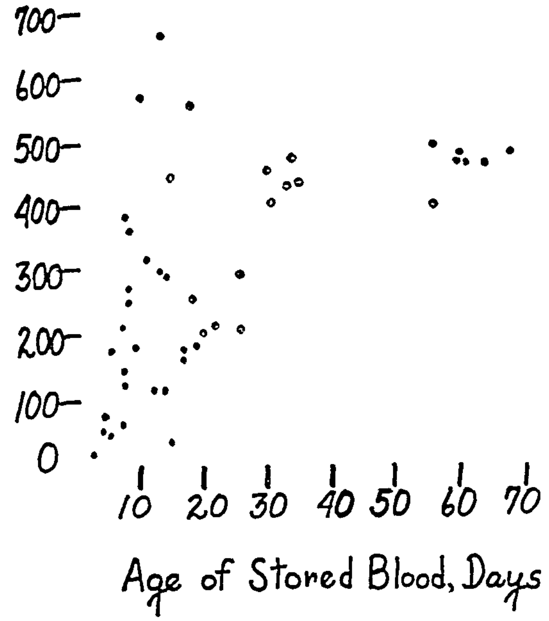
ultaneous measurements on blanks and standard ntities of ammonium sulfate. The duplicate blood serum determinations always checked within less n 2%.



Ammonia-nitrogen (NH_3N) content of stored blood sampled various intervals.

The data demonstrate that the ammonia-nitrogen content increases with aging of the stored blood. At 21 days, the maximum age of blood permitted for use for transfusion, the ammonia-nitrogen content of most samples of whole blood was under 250 mcg. per 100 ml. (see table and figure). That amount is much less than that found by Cincotti.[3] The discrepancy may be explained by differences in methods of collection and storage or by variations in the techniques of measuring the ammonia. In view of both our data and Cincotti's, the amounts of ammonia nitrogen that would be administered with 1,000 ml. of 21-day-old blood would exceed that of fresh blood by 2 to 8 mg., the equivalent of 6.6 to 30.4 mg. of ammonium chloride. Whether or not those extremely small quantities have clinical significance is debatable.

The blood used in this study was supplied by the Irwin Memorial Blood Bank.

ATRIAL FIBRILLATION DUE TO ACCIDENTAL ELECTRIC SHOCK

William H. Wehrmacher, M.D., Chicago

Of the several causes of atrial fibrillation in man, lectric shock has received only scant attention. A few revious case reports demonstrate that the arrhythmia nay result from accidental shock[1] or as a complicaion of electric convulsive-shock therapy.[2] Patients so fflicted are naturally concerned about what the nticipated course of the illness may be. Physicians equire knowledge of how it develops and how it can e treated. Those concerned with the adjudication of laims arising from such injuries need information about the prognosis. The following case demonstrates how electric shock may produce atrial fibrillation and that excellent functional recovery can follow such an accident.

Report of a Case

The patient, a 52-year-old lineman, on Sept. 2, 1954, was working astride a pole which supported high-tension electric wires. As he worked, he inadvertently assumed a position whereby his left posterior thorax, wet with sweat and covered by only a cotton workshirt, touched a noninsulated 2,200-volt line above, while his right forearm simultaneously contacted a 110-volt line below, which was guarded by a weathered insulation. The contact was transient, caused him to jerk away, and produced a buzzing sound heard by a nearby workman. The patient continued to work and finished the job he was doing.

When seen by the medical department of his employer's firm on the day after the accident, burns of about 1 mm. depth on the right arm and left posterior thorax were evident. An electrocardiogram (fig. 1) confirmed the examining physician's impression that the patient's atria were fibrillating and that ventricular contractions were absolutely irregular. A second electrocardiogram taken the same day showed persistence of the atrial fibrillation. The next electrocardiogram, taken Sept. 7, and all subsequent electrocardiograms showed that the abnormal rhythm spontaneously had reverted to normal.

There was no suggestion that any disturbance of cardiac rhythm had ever occurred previously, either as observed by the patient himself, his private physician, or the employer's medical department.

Examination on Sept. 10 was made to evaluate his cardiac status. His pulse was regular, normal in volume and contour, and beat 72 times per minute. Systolic blood pressure varied

---

From the Department of Medicine, Northwestern University Medical School.

between 140 and 146 mm. Hg and diastolic between 88 and 96 mm. Hg. The retinal arteries showed very slight changes, corresponding to a bare grade 1 (Keith and Wagoner) arteriolosclerosis. The walls of the medium-sized peripheral vessels were very slightly firmer than average. The lungs were normally resonant and the breath sounds normally vesicular bilaterally except for inconstant sticky rales at the lung bases. The heart tones were of good quality. No murmurs were audible. There was a superficial burn on the right forearm and a multiple-base skin burn of about 1 mm. depth over the upper portion of the left scapula.

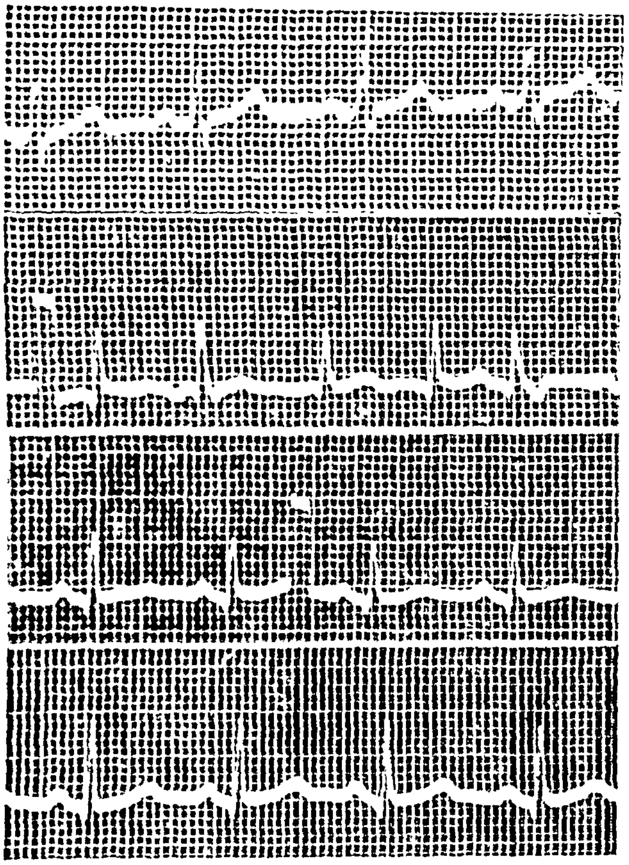

Fig. 1.—Standard lead 2 of electrocardiograms in case reported. The top graph, taken Dec. 20, 1946, shows a normal sinus rhythm. The second graph, taken Sept. 3, 1954, the day after the electric shock, shows atrial fibrillation with absolute irregularity of ventricular rhythm. The last complex from this graph represents a premature beat of ventricular origin, whereas all others are conducted beats from irregular atria. The last two graphs, taken Sept. 7, 1954, and Nov. 5, 1954, respectively, show return and persistence of a normal sinus rhythm.

The chest was examined by fluoroscopy. The heart was at the upper limit of normal size. The configuration of the heart, which lay rather transversely in the sthenic chest, suggested some prominence of the left ventricle.

All electrocardiograms (fig. 1 and 2) known to have been recorded from this patient were made available for study. The first electrocardiogram, a routine part of his employer's medical program, was made in 1946 when the patient was 44 years old. It showed a normal sinus rhythm and normal conduction. In lead 3, the QRS was a W-shaped complex and the T wave was inverted. Because of the possibility that this abnormality might have resulted from a posterior myocardial infarction, a careful inquiry for suggestive symptoms was made, but the patient disclaimed any. Electrocardiograms taken Sept. 3 (the day after the electric shock) showed atrial fibrillation and occasional premature beats, arising from at least two different ventricular foci. At this time, the T wave was flat in lead 2 and inverted in 3 and aVF. In leads 3 and aVF, there were initial Q waves, and in leads 2 and V6, there were tiny Q waves. Leads aVF and V6 were not taken in 1946, so no comparison could be made.

On Sept. 7, the regular sinus rhythm had been restored there was less flattening of the T wave in lead 2 and le version of the T wave in leads 3 and aVF. There was no ther change in the QRS complexes from that recorded on S 3. Such QRS changes might conceivably have resulted f previous damage of the posterior wall of the heart. No r tionship between the QRS changes and the electric shock c be established. The transient and limited repolarization cha are less than one would ordinarily associate with a recen farction of the myocardium but correspond well with tho sociated with the onset of rapid heart action and arrhyth Subsequent tracings demonstrated continued normal rhyth

Atrial fibrillation discovered during the first examination shock, its timely restitution to a normal sinus rhythm, its fa to recur as would be expected in paroxysmal atrial fibrilla and its resemblance to other instances resulting from ele convulsive shock therapy [2] or accidental shock [1] indict the e tric shock as the cause of atrial fibrillation in this case.

Reexamination 10 months after the shock supported the pa tient's own contention that he was well. His blood pressure w 144/90 mm. Hg and his pulse regular at 72 beats per min After 25 trips mounting and descending from a 9-in. step wi three-quarters of a minute, his pulse rate rose to 90 beats p minute and returned to less than the resting rate (60 beats p minute) within three minutes after completing the exer A ballistocardiogram showed no significant abnormalities. T fluoroscopic appearance of the chest and heart was unchan from that of 10 months previously.

The patient continued well until last seen approximately t years after the accident. No relapse or subsequent rhythm d turbance was observed. Although the employer changed t patient's duty assignments to those which no longer requi work with high-tension circuits or exertion, the patient had n cardiac symptoms. When not at work, he climbs stairs as read as ever, does simple carpenter work on his home, and d some gardening.

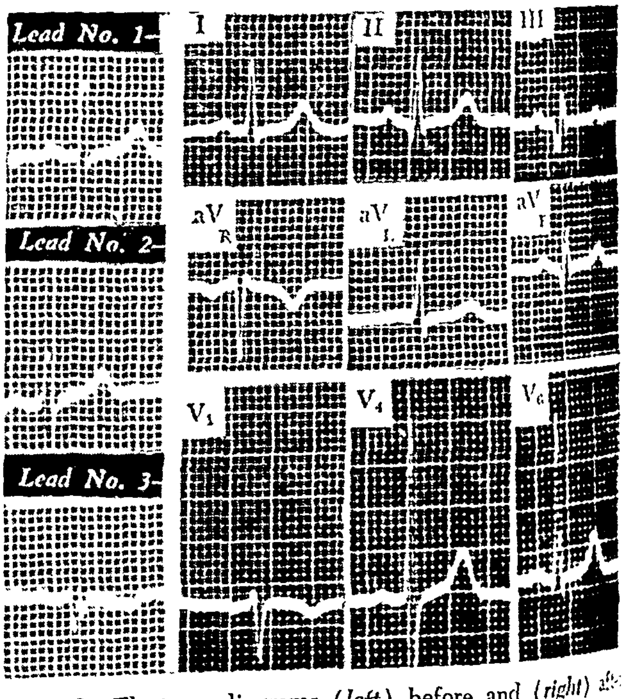

Fig. 2.—Electrocardiograms (*left*) before and (*right*) af recovery from electric shock.

Comment

Electric shock may produce a great variety of in juries, ranging from a simple unpleasant tinglin sensation to sudden death. The nature and extent o the injury is determined by the intensity of the curre its frequency, its pathway through the body, and it duration.

The peculiar effects of electricity upon the heart ve intrigued investigators since the time when only mitive sources of electricity were available. In the h century Abilgaard[3] used the Leyden jar to proce a shock of sufficient intensity to "kill" chickens ich he subsequently would "revive" by a second untershock. More recent investigators have demonated that an electric stimulation of the animal art may produce a variety of arrhythmias varying m a simple premature systole to ventricular fibrillan. Although the latter has never been conclusively monstrated to be produced by electrical stimulation the human heart, and further study of this point is arly needed, it is usually considered to be the mode sudden death incident to electric accidents.

The variety of cardiac responses to electrical stimution depends not only upon an adequate intensity of e stimulation but also upon the phase of the cardiac cle when it is applied. Nothing results from stimulan during the refractory phase alone. A short shock tween beats usually produces a simple premature at. A strong shock, occurring during the period of minishing contraction of the ventricles (that is, corsponding to the time of the T wave of the electrordiogram) produces ventricular fibrillation in the nimal[4] and commonly eventuates in its death. As the uration of an electric shock is increased, the chances at it will occupy this critical period of the cardiac ycle increase, as does its lethal potency.

Induction of fibrillation of the atrium of the heart y direct stimulation is ordinarily difficult. However, uring simultaneous stimulation of the vagus nerve, he threshold of the atrium is reduced, atrial fibrillation s easily induced, and the fibrillation will persist after he direct stimulation is stopped.[5] This fact, known ince shortly after the turn of the century, was clariied by Andrus, Carter, and Wheeler[6] in 1930. They lemonstrated that vagus stimulation shortened the efractory period of the atrium: "Due, however, to he shortening of the refractory period consequent upon stimulation of the vagus, they [the shock stimuli] fell upon tissue which was excitable but in which conductivity had, presumably, not yet returned to normal." In the case herein reported, a similar nechanism may be involved. Working in an ungainly [illegible] astride a pole certainly induces one to strain when changing position. Such straining accomplishes the essential features of the Valsalva maneuver, a potent natural method of increasing vagus tone. While this hypothesis does not lend itself to experimental confirmation, it is tenable and correlates the clinical situation observed with experimental studies.

The favorable outcome observed here corresponds with previous reports. In most instances, the rhythm returns to normal spontaneously or after the administration of either digitalis or quinidine. The latter, pharmacologically, seems to be the drug of choice; but neither was necessary in the case reported here. In one case, reported by Hickl,[1g] the rhythm did not revert to normal during a short period of observation; but one might conjecture that such could have been accomplished with treatment.

The gratifying lack of evident cardiac sequellae likewise corresponds to that in previous reports. Although the patient in our case has been protected by his employer subsequent to the accident, he has been none the worse for its occurrence.

Summary

Atrial fibrillation resulted from accidental electric shock received by a 52-year-old lineman during his work. The altered rhythm reverted spontaneously to normal within a few days. Recovery was apparently complete.

Addendum

In July, 1957, the patient's work record was reviewed. He was continuing to work full time. His only absences from work subsequent to the accident were the few days incident to healing of the skin burn and a period of nine days after an automobile accident in 1955.

670 N. Michigan Ave. (11).

ASIAN INFLUENZA

IN THIS issue of THE JOURNAL (page 356) the nine-man Special Committee on Influenza of the American Medical Association publishes its first comprehensive report on the Asian influenza situation. The conclusions arrived at are the result of several meetings in Washington, D. C., with U. S. Public Health Service officials, a special meeting with the State and Territorial Health Officers Association, individual and group consultations with experts in the field of communicable diseases, and, finally, meetings of subcommittees and the Committee itself, to draw up the final statement.

The Committee was guided in part by the correspondence and many questions received by THE JOURNAL, and other A. M. A. departments, which helped to direct the final draft toward a practical all-encompassing reference. While the special report is as up to date as it is possible to publish at this time, the Committee is aware that any change in the incidence of reported cases, or in the virulence of the virus, might warrant a completely new approach toward the disease.

As of now, however, the clinical course of the disease remains moderate. There have been very few deaths reported from the disease itself. Where secondary bacterial infections do develop, it is anticipated that adequate chemotherapy will lessen the severity of such sequelae. The probability of an epidemic of Asian influenza this fall or winter is great, but a satisfactory vaccine has been developed, which should prevent the loss of essential community services due to the disease.

There is a difference of opinion concerning the dosage for adults. While the consensus favors 1 cc. subcutaneously, some believe that 0.1 cc. intracutaneously is adequate, especially since it reduces the severity of reactions. Even some laboratory studies are reported to support this belief. Furthermore, since many believe that the dose should be repeated within two weeks regardless of how it is administered, there is argument that the intracutaneous route will conserve supplies. However, until more data are available the physician will have to determine for himself how it should be given to his individual patients. He must not forget, though, that this vaccine is made from viruses grown on eggs, and patients who have a history of allergy may experience unusually severe reactions. Additional studies are now under way, vaccine production is being increased rapidly, and purity and potency of preparation are being closely examined. As information on these subjects becomes available it will be reported from time to time in THE JOURNAL.

KENTUCKY'S PIONEER PLAN

Four-way cooperation on a "doctor for your community" program in Kentucky might well be examined by other states whose own rural areas suffer from poor distribution of physicians. In the Organization Section of this issue (page 355) is a brief report describing how the Physicians Placement Service of the Kentucky State Medical Association, the Board of the Rural Kentucky Medical Scholarship Fund, the University of Louisville School of Medicine, and the state general assembly are working together to bring adequate medical care t communities which previously had failed to fin physicians.

It is a cooperative program in the truest sense—bringing out the best efforts of medical educator practicing physicians, medical association official businessmen, lay organizations, civic leaders, stat legislators, and other Kentuckians. The progra offers qualified medical students at the Universi of Louisville School of Medicine two financial i- ducements to practice in certain areas which are in critical need of doctors: full-tuition loans at the rate of $900 a year, and/or full refunds of past tuition payments.

The loan fund is financed by contributions from physicians, lay groups, and individuals, and grants of the general assembly. The state legislators also have voted to spend up to $500,000 a year in tuition refunds for University of Louisville School of Medicine alumni who practice in designated communities.

The two-pronged plan as it succeeds in Kentucky is not necessarily a panacea for other states which face isolated community doctor shortages. But it does illustrate that cooperative action at the state level might be the catalyst which accelerates solution to a physician maldistribution problem which knows no specific boundaries. It is an experience worth study, an experiment worth praise.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

As you may know, the House of Delegates of the American Medical Association at the Annual Meeting last June in New York reaffirmed its long-standing opposition to the compulsory coverage of physicians under the Old-Age and Survivors Insurance provisions of the Social Security Act.

At the June, 1957, New York meeting the House of Delegates also recommended a stepped-up informational program designed to reach every member of the Association and to explain the reasons underlying the position of the House on this issue. In the weeks and months ahead, therefore, I urge you to give careful attention to all educational materials dealing with Social Security coverage for physicians.

It has become more than ever imperative for physicians to study this subject closely because, for the past year or more, the Committee on Social Security for Physicians of the Physicians Forum has been confusing the issue with a barrage of dubious propaganda. The Physicians Forum, as many of you will recall, was the only American medical organization which supported national compulsory health insurance during the 1949-1952 debate on that proposal. Now, in 1957, many doctors question whether the Physicians Forum is really interested in OASI benefits for the profession or is actually concerned with that subject only as a stepping stone to help accelerate further expansions of the over-all Social Security system.

This is no mere academic question. It involves the consistency of the medical profession's historic position on the broad issue of individual enterprise versus government-planned security. In recent years our profession, probably more than any other single group, has resisted the socialist trend in this country and has stoutly defended the qualities of self-reliance and individual initiative.

We must bear in mind that the Social Security system, which some physicians would like to join, is the very same mechanism through which the American medical profession could eventually be socialized. Already enacted as amendments to the Social Security Act are the waiver of premium for disabled workers and the payment of OASI benefits at age 50 to persons with so-called permanent and total disability. Already proposed as amendments to the Social Security Act are the lowering or elimination of the age-50 qualification for permanent disability benefits, cash payments for the dependents of disability beneficiaries, cash benefits for temporary disability, "free" hospital care for OASI pensioners over 65, full-fledged national compulsory health insurance, and a wide variety of other expansions.

If physicians ever requested coverage for OASI benefits, would they not be placing themselves in a more difficult position to oppose many future proposals which would directly affect the shape of medical practice and medical care? Would they not be vulnerable to the charge that they are willing to accept a little bit of socialism for a personal financial benefit, but are opposed to other bits of socialism designed for the general public? These are among the many questions which physicians must decide in the immediate future.

They also must become informed about a variety of practical considerations. For example, is the Social Security system on a sound actuarial and financial basis, particularly in view of its tremendous future liabilities? Is it "insurance," offering a specified contract with stated premiums and guaranteed benefits? What is the truth about the "trust fund"? How many physicians would ever benefit from the retirement provisions under OASI?

When physicians study the answers to these and other questions, I am confident that the Association's policy will be upheld by an overwhelming majority.

David B. Allman, M.D., Atlantic City, N. J.

ORGANIZATION SECTION

SOCIAL SECURITY DISABILITY PROGRAM

The Committee on Medical Rating of Physical Impairment of the Board of Trustees reports the following recent developments in the Old-Age and Survivors Insurance disability program under the Social Security Act.

On July 17, 1957, President Eisenhower signed Public Law 109, which makes two changes in the program. These changes are:

1. The filing period is extended to July 1, 1958, during which applications for benefits may be made and the beginning period of an applicant's disability may still be established as early as the actual onset of disability provided all other requirements of the law are met. This change will benefit those individuals whose disability began some time ago and who did not apply for benefits before the previously established date of July 1, 1957, despite extensive efforts to publicize the need for timely filing.

2. Benefits will be paid concurrently to eligible veterans receiving compensation by the Veterans Administration for service-connected disability.

On June 30, 1957, the first regulations pertaining to disability under this program were published in the *Federal Register* (page 4362, vol. 22, number 119):

Meaning of disability; benefits based on disability

(a) Among the requirements an individual must meet to be entitled to disability insurance benefits, or to child's insurance benefits after attainment of age 18, is that he be unable to engage in any substantial gainful activity because of a medically determinable impairment and that his impairment be expected to continue for a long and indefinite period of time, or to result in death.

(b) In determining whether an individual's impairment makes him unable to engage in such activity, primary consideration is given to the severity of his impairment. Consideration is also given to such other factors as the individual's education, training and work experience.

(c) It must be established by medical evidence, and where necessary by appropriate medical tests, that the applicant's impairment results in such a lack of ability to perform significant functions—such as moving about, handling objects, hearing or speaking, or, in a case of mental impairment, reasoning or understanding—that he cannot, with his training, education and work experience, engage in any kind of substantial gainful activity.

(d) Whether or not the impairment in a particular case constitutes a disability is determined from all of the facts of that case. Examples of some impairments which would ordinarily be considered as preventing substantial gainful activity are set out in paragraph (e) of this section. The existence of one of these impairments (or of an impairment of greater severity), however, will not in and of itself always permit a finding that an individual is under a disability as defined in the law. Conditions which fall short of the levels of severity indicated must also be evaluated in terms of whether they do in fact prevent the individual from engaging in any substantial gainful activity.

(e) The examples are:

(1) Loss of use of two limbs.

(2) Certain progressive diseases which have resulted in the physical loss or atrophy of a limb, such as diabetes, multiple sclerosis, or Buerger's disease.

(3) Disease of heart, lungs or blood vessels which has resulted in major loss of heart or lung reserve as evidenced by X-ray, electrocardiogram or other objective findings so that, despite medical treatment, it produces breathlessness, pain or fatigue on slight exertion, such as walking several blocks, using public transportation or doing small chores.

(4) Cancer which is inoperable and progressive.

(5) Damage to the brain or brain abnormality which has resulted in severe loss of judgment, intellect, orientation or memory.

(6) Mental disease (e. g., psychosis or severe psychoneurosis) requiring continued institutionalization or constant supervision of the affected individual.

(7) Loss or diminution of vision to the extent that the affected individual has central visual acuity of no better than 20/200 in the better eye after best correction, or has an equivalent concentric contraction of his visual fields.

(8) Permanent and total loss of speech.

(9) Total deafness uncorrectible by a hearing aid.

(f) Under the law, an impairment must also be expected either to continue for a long and indefinite period or to result in death. Indefinite is used in the sense that it cannot reasonably be anticipated that the impairment will, in the foreseeable future, be so diminished as no longer to prevent substantial gainful activity. Thus, for example, an individual who suffers a bone fracture that has prevented him from working for an extended period of time will not be considered under a disability if his recovery can be expected in the foreseeable future.

(g) Impairments which are remediable do not constitute a disability within the meaning of this section. An individual will be deemed not under a disability if, with reasonable effort and safety to himself, the impairment can be diminished to the extent that the individual will not be prevented by the impairment from engaging in any substantial gainful activity.

SAFETY CONGRESS

The physicians of America will again join in presenting a program this fall at the National Safety Congress in Chicago. The A. M. A. Council on Industrial Health will co-sponsor a session, concerning vision in industry, with the American Society of Safety Engineers and the National Safety Council occupational health nursing section. Among the topics to be covered in the discussion of ocular safety programs are visual ability to meet job requirements, ocular protection, and proper first aid for ocular injuries. This program will be held on Thursday morning, Oct. 24, at the Congress Hotel.

PUBLICIZED TREATMENT FOR AMYOTROPHIC LATERAL SCLEROSIS DISCOUNTED

Major John T. Godfrey, U. S. A. F., reserve officer in the United States Air Force, is a victim of Lou Gehrig's disease, technically known as amyotrophic lateral sclerosis. Major Godfrey was flown to Schwenningen, West Germany, in early June, 1957, for treatment by Dr. Arthur Boss in that city. There was considerable newspaper, radio, and television coverage of this, and this coverage led to interest on the part of patients with similar diseases considering going to Germany for treatment by Dr. Boss. There were numerous inquiries regarding this treatment addressed to the National Institutes of Health, the surgeon general of the Air Force, and the American Medical Association, and members of Congress were besieged by their constituents. Because of this the surgeon general of the Air Force and the American Medical Association, Washington Office, requested that Dr. Francis M. Forster, while he was in Europe, visit Major Godfrey and Dr. Boss in Schwenningen. This visit had the approval of the German government in Bonn.

Dr. Forster is a member of the A. M. A.'s Council on Mental Health and of the Section on Nervous and Mental Diseases. He also is dean and professor of neurology at Georgetown Medical School and president of the American Academy of Neurology. In addition, he serves as a consultant in neurology to the surgeon general of the U. S. Air Force. On July 17 Dr. Forster visited the German doctor, Arthur Boss, in his clinic at Schwenningen, West Germany, and later prepared the following statement for the U. S. Air Force and the American Medical Association:

> Not having seen Major Godfrey professionally prior to July 17, 1957, I am at somewhat of a disadvantage in evaluating the possible effects of the therapeutic regime. However, Major Godfrey definitely presents at this time the classic clinical picture of amyotrophic lateral sclerosis, and there is no objective evidence of recovery from his neurological deficit. Dr. Boss is himself cautious and to quote him he is "skeptical." Dr. Boss will not divulge the nature of his treatment, and this is quite difficult to understand since physicians from ancient times are bound by the Oath of Hippocrates to share their knowledge with other physicians, and in modern times this is accomplished through writings in medical journals and by presentations at medical meetings. Dr. Boss states he has been using his treatment for 16 years but he has failed to publish it. It is unfortunate that Dr. Boss has not seen fit to present his therapy at the International Congress of Neurology being held at Brussels next week. I am advised that the lack of disclosure of therapeutic methods is contrary to the principles of the German Medical Societies. While the treatment has been employed by Dr. Boss for 16 years, he has not controlled his studies nor has he used precise, scientific follow-up procedures to evaluate his results. He states that he has "heard from patients two to three years after treatment" and he has concluded from this that they are cured.
>
> The entire medical profession and scientific societies hope and strive for the successful treatment of crippling diseases. This disease in particular has long been a target for neurological research and efforts. The possibility that Dr. Boss' treatment will succeed is remote; however, and to quote Dr. Boss "it can be a very dangerous treatment," and "it is not always successful." Since the treatment can be dangerous, it is not yet accepted nor indeed divulged and has not been scientifically evaluated. Treatment of larger numbers of patients is definitely contra-indicated at this time.

"DOCTOR FOR COMMUNITY" PROGRAM

The first physician to be refunded medical school tuition under a new "doctor for your community" program is J. W. Walker of Mount Vernon, Ky. Early last month he received a check for $900—half the tuition paid toward his graduation from the University of Louisville School of Medicine in 1945—because he chose to practice in Rockcastle County, which had been in critical need of medical care. If Dr. Walker remains in Mount Vernon, and that was his intent, he will receive another $540 next year. and the balance of his tuition, $360, the following year.

Any University of Louisville Medical School graduate is eligible to participate in this program set up by the school and the Kentucky general assembly. which has voted to grant up to $500,000 a year in state aid to bring more adequate medical care to designated rural areas. This month Dr. Robert E. Cornett of Jackson, Ky., was scheduled to receive $1,600, the first refund installment of his four-year tuition, for practicing in Breathitt County. (Tuition had increased in the 10 years since Dr. Walker graduated.)

Refund of tuition is one of two pioneer programs being pursued by organized medicine to relieve a shortage of physicians in certain "critical" areas of Kentucky. The state medical association is also co-sponsoring (with the University of Louisville School of Medicine and the Board of the Rural Kentucky Medical Scholarship Fund, headed by Dr. C. C. Howard) a loan plan for qualified medical students at the school. Under this project, benefiting 17 new students for the new academic year, annual loans of $900 are made. They are to be repaid at 2% interest after graduation, but if the borrower then practices in one of 10 rural Kentucky counties in dire need of medical care, the yearly loans are successively forgiven for each year of practice.

"Counting interest on the total loan, plus the $3.-200 tuition refund," said Dr. Howard, "a medical student now can get a total of about $7,000 if he practices in a critical area of the state."

During the past decade the scholarship fund has benefited more than 100 students through over $200,000 in finances contributed by physicians, other individuals, and organizations in Kentucky; last year the state general assembly appropriated its first annual $25,000 for the fund. Applicants need not be native Kentuckians—recipients this fall at the University of Louisville School of Medicine include one youth from Indiana and a young woman from California (who heard about the loan plan from the American Medical Association).

The state medical association's Physicians Placement Service committee, headed by Dr. Delmas M. Clardy of Hopkinsville, makes available to inquiring doctors a descriptive list of Kentucky communities which need help in securing medical service. (See editorial on page 352 of this issue.)

A. M. A. PREPARES LIABILITY KITS

For use in claims prevention and claims review programs, the A. M. A. Law Department is making available to each state medical society a packet of materials dealing with medical professional liability. The kit will contain reprints from the "Medicine and the Law" section of THE JOURNAL which deal with statutes of limitation, court decisions, and *res ipsa loquitur*. The results of an opinion survey and a report on medical professional liability case histories—keyed to each state—will also be included. Distribution is slated for Oct. 1.

SPECIAL COMMITTEE ON INFLUENZA

ASIAN INFLUENZA—A SPECIAL REPORT TO PHYSICIANS

The following report, prepared by a subcommittee consisting of Drs. Cortez F. Enloe Jr., Chairman, New York; Max L. Lichter, Detroit; and David Henry Poer, Atlanta, Ga., in consultation with the Surgeon General, U. S. Public Health Service, is presented for the guidance of the medical profession by the A. M. A. Special Committee on Influenza and has been authorized for publication in THE JOURNAL. FRANK W. BARTON, *Secretary.*

The A. M. A. Special Committee on Influenza has arrived at the following conclusions:

a. The probability of an epidemic of Asian influenza this fall or winter is great;

b. The United States population has no natural immunity to this type of influenza;

c. The most satisfactory vaccine possible has been developed;

d. The supply of this vaccine should soon be adequate to protect essential national services;

e. The vaccine is safe, except in patients with known allergy to eggs;

f. The course of the disease is moderate, in most patients, and there have been very few deaths reported due to the disease;

g. It is possible, but not probable, that the disease will increase in virulence; and

h. Chemotherapy is not considered effective in uncomplicated influenza cases. If secondary bacterial infection should result as a complication, it is anticipated that adequate antibiotic or sulfonamide therapy will lessen the seriousness of sequelae.

The occurrence of the "influenza epidemic" was first reported in the New York *Times* on April 17, 1957. At the suggestion of the Walter Reed Army Institute of Research, the 406 Medical General Laboratory of the Army in Japan was ordered to investigate the Hong Kong outbreak and within 30 days the responsible virus was isolated and identified as a new and different strain. In another 30 days (by late June), the first batch of vaccine had been manufactured by the Walter Reed Army Institute of Research and delivered to the National Institutes of Health, Public Health Service, for testing. This is a record to be proud of.

The history of epidemics of influenza shows that this virus generally does not change in virulence during an epidemic. As Dr. M. R. Hilleman of Walter Reed Army Institute of Research, who identified the Asian strain of the virus, has reported, the capacity for continuous and progressive alteration in antigenic composition is essential to the survival of influenza virus in the partially immune human host population. Because of this constant change, which at times may be very great, the physician with many cases of influenza must maintain prudent vigilance and the virologist must "sleep with one eye open." Having studied the behavior of the present virus, most authorities agree that the mortality in the first epidemic of Asian influenza will be low. However, physicians must recognize that we are dealing with an agile, chameleon-like microorganism which could return in a different guise after a brief pause for change of character—just as

---

The Special Committee on Influenza consists of Drs. Harold C. Lueth, Chairman, James Z. Appel, Cortez F. Enloe Jr., Carroll P. Hungate, Hugh H. Hussey Jr., Max L. Lichter, David Henry Poer, Roscoe L. Sensenich, and Charles W. Steele.

it apparently did in the mild epidemic of the spring of 1917 and the catastrophic invasion in the winter of that same year.

A study of the world epidemiology patterns of Asian influenza and the confirmed outbreaks in the United States thus far leads to the inescapable conclusion that the country has been well seeded.

The Asian influenza was initially observed in Hong Kong. Then, Malaya, India, and the Philippines were hard hit; then Taiwan; then Japan. During this time, it appeared in U. S. Navy personnel who had visited these areas. By now, it has occurred in most countries, but not yet in epidemic proportions in all of them.

Here are a few case histories of how Asian influenza has spread, given to the Committee by C. C. Dauer, M. D., chief of the National Office of Vital Statistics.

A girl who attended a conference in Davis, California, where influenza broke out, traveled by train with others from that State to a conference in Grinnell, Iowa. The girl became ill before reaching her destination, and about a dozen of her fellow travelers were the first of about 200 cases that developed within a few days in Grinnell. A similar illness developed in many of the 1,700 delegates after leaving the conference. In another instance, a group of 35 foreign exchange students and two chaperones left San Francisco by bus for New York. Eighty percent of them were ill on or after their arrival in Salt Lake City. They were housed in private homes in Salt Lake City and 14 of the household contacts subsequently had influenza-like illnesses. A small group attending a religious conference in Kentucky experienced an outbreak of influenza. Delegates came from a number of States, but the first to become ill were those from California. The story of influenza at the Boy Scout Jamboree at Valley Forge, Pennsylvania, is still unfolding. Several scouts in a contingent from California were ill on board a train to New York and others developed respiratory infections after their arrival. The infection was mild, and doubts were expressed that the illness was influenza. Other cases of respiratory infection occurred at the Jamboree, at least one or two in nearly every State group. By the time the Jamboree ended, it was known from laboratory reports that influenza was present in the California group of cases and, as expected, many cases developed among various groups after the Jamboree. The fifth and last outbreak traced to California was in Corpus Christi where Navy personnel or their dependents developed the disease following the transfer of about 20 persons from San Diego. In the latter area, there had been an outbreak among recruits of the training station. Each of the five outbreaks described very briefly above has been confirmed by isolation of influenza type A viruses which were antigenically similar to the new Asian strain.

Two other illustrations can be given which show very clearly how influenza infection has been carried from one country to another. Such pathways were seldom traced in previous epidemics.

About 10 days after a number of U. S. Navy vessels had visited Valparaiso, Chile, an outbreak began in that country. Influenza-like illness had occurred on board at least one vessel, and one of them had come from a port in the United States where an outbreak of influenza had occurred. The epidemic began about July 22nd in Santiago and Valparaiso and, in the course of the next two or three weeks, about 25 to 30 percent of the population in cities were estimated to have been affected. About August 1st, crew members of a Chilean airline arrived in Miami, Florida, ill with influenza. Thus, the infection seems to have been carried from the United States to Chile and then brought back. The other instance concerns a group of foreign exchange students from several countries who arrived in New York earlier this month. Forty-four Turkish students traveled by train to western Europe. Cases of influenza developed in the group when they reached Belgrade and still others when they arrived in Vienna. A group of Austrian students boarded the train in Vienna and accompanied the Turkish students to Rotterdam. Because of the illness among them, the Turkish students were refused passage on a ship that was to take all of the students to New York. They arranged for passage on a plane and on arrival in New York, 9 more of them were ill. Five days later, the ship that carried about 650 students as tourist class and 200 other passengers arrived in New York with 50 active cases of influenza. Illness on the ship began in the Austrian contingent, and 150 to 200 were ill at some time during the voyage from Rotterdam. There was only one case in the nonstudent passengers and one in a crew member. Sick students were isolated in quarters after debarking in New York. One of them—a 17-year old boy from Greece—later showed signs of pneumonia and circulatory failure. He was hospitalized and died within 24 hours. Postmortem examination revealed a hemorrhagic pneumonitis. A coagulase positive staphylococcus was isolated from lung tissue, and an Asian strain of influenza A virus was recovered from lung and heart tissues. Four students who proceeded from New York to their destinations in New Hampshire, New York State, and California were reported to have developed influenza-like disease on arrival.

The lesson to be learned from these experiences is that the disease will cross national and state boundaries no matter what controlled measures are taken and it cannot be stemmed in communities by closing schools or other places of assembly.

Vaccination is the only means available today for the control of Asian influenza. To this end, a remarkable and prodigious effort has been put forth.

Recognizing that Asian influenza is an air-borne virus infection that cannot readily be controlled by the usual preventive measures, mindful of the efficacy of the vaccine, and aware of the problem of supply and distribution, the Special Committee on Influenza urges each physician to be guided, insofar as possible, by the following routine:

1. Preferably give 1 cc. of vaccine subcutaneously to adults.
2. The intracutaneous administration of 0.1 cc. may be used in lieu of the above-described method.

This vaccine contains 200 CCA (chick-cell-egg-agglutination) test units per cubic centimeter. Significant adverse reactions have been rare, according to the U. S. Public Health Service, although pain at the site of injection commonly occurred in 700 test patients. Of these, only one missed a day's work. The vaccine should not be administered to persons sensitive to eggs. Persons who are known to be allergic to eggs or chicken feathers may react unfavorably. Reactions among the aged are no more frequent than in other adults; however, the physician should give special consideration to very old patients with existing illness.

The Committee endorses the recommendations of the American Academy of Pediatrics concerning the administration of the influenza vaccine to children:

For preschool children (3 months to 5 years): 0.1 cc. intradermally or subcutaneously, repeated after an interval of one or two weeks.

For children 5 to 12 years of age: 0.5 cc. subcutaneously, repeated after an interval of one to two weeks.

For children of 13 years of age and older, the dose for adults (1.0 cc. subcutaneously in a single injection) may be used.

Although some individual physicians may have access, on occasion, to an adequate supply of the vaccine for their patients, the Committee hopes they will be reminded the vaccine is in short supply. For this reason, the Committee endorsed and adopted a resolution passed by the State and Territorial Health Officers in a meeting on Aug. 28, 1957, in Washington, D. C., which was referred to the Surgeon General, Public Health Service, for consideration. That resolution, dealing with the establishment of priorities to be given in the administration of the vaccine, recommended that priority be given to:

(1) Those individuals whose services are necessary to maintain the health of the community

(2) Those individuals necessary to maintain other basic community services

(3) Persons with tuberculosis and others who in the opinion of the physician constitute a special medical risk

The above recommendation is merely a guide and should be considered in the light of local conditions and situations. Certain local and state societies, alert to the problem, have already established priority groups in slightly different versions which the Special Committee recognizes as meeting problems peculiar to the involved areas.

Vaccine will be available in limited amounts for the next 30 days, and the prospects are that the supply will be larger after that time. Until such time when the supply of vaccine is adequate, the free and voluntary cooperation of each physician in adhering to locally established priorities is essential to the protection of the nation's health and vital services.

The Committee again emphasizes and urges each constituent medical society to take the lead in planning now, if they have not already done so, to meet the emergency problems of a possible influenza epidemic. A number of state medical societies are utilizing their state emergency medical service committees, since they are uniquely prepared and organized for emergency situations.

In the formulation of local plans, consideration should be given to expanded professional care through the utilization of all medical personnel, regardless of type of practice. Plans should include mobilization of other professional resources, such as nurses, nurses' aides, pharmacists, appropriate health and lay groups, and others. Action to make full use of hospital facilities should be explored, such as curtailment of elective surgery, diagnostic studies, etc. The Committee recommends that state and local programs be coordinated with public health agencies and state and local health departments. There should be close cooperation concerning diagnosing and reporting influenza cases. Joint planning may be advisable in many areas.

It is evident from experience gained in poliomyelitis outbreaks that the public looks to the medical profession and public health officials for leadership in these emergency situations. Each community should make a serious study of available resources and facilities and have suitable informational and educational programs to cope with epidemics that might occur. Constituent medical societies should take appropriate action to acquaint the general public with the plans and operational facilities being readied by the profession to cope with the emergency problems and should reassure them that there is no cause for alarm concerning an influenza outbreak in view of the fact that the illness is of short duration, it is generally mild and with few complications, and it has a very low mortality rate. Great reliance must, of necessity, be placed on home care in view of the high incidence rate which may be anticipated. Medical societies should plan for the dissemination of information to the public on symptoms and home care of patients.

In considering the disease itself, it has been estimated that 20% of those who have not been vaccinated for Asian influenza, and the same percentage of the 3 of every 10 whom the vaccine does not protect, will contract the disease. If this occurs, the outbreak in the community will probably be explosive and last for four or five weeks until the disease runs its expected course.

As in all instances when a disease is widespread, there is a tendency to attribute the symptoms of most patients one sees to the new disease. Physicians must be particularly aware of this fact. As one Army physician put it, doctors should remember that "all that fevers is not flu."

The symptoms consist of chills that occur with very little warning, and temperature that climbs to 103 or 104 F (39 to 40 C) and undulates in that range for from three to four days. The fever is accompanied by headache and general muscle pains. As the fever subsides, the aches and pains gradually vanish, the patient is generally left weak. The patient can expect to endure this convalescent period for another few days while normal health returns.

There is actually no specific therapy for the patient with Asian influenza. It is axiomatic that the person in health with the best nutritional status stands the best chance in a bout of any infectious disease. Once it strikes, bed rest, forced fluids, and symptomatic treatment are recommended. In a report that appeared in the Sept. 7 issue of The Journal, page 58, the Council on Drugs stated that little help can be expected from the sulfonamides or antibiotics when the condition is confined to influenza alone. However, should complications (e.g., pneumonia) occur or even be suspected, the patient should be hospitalized and appropriate chemotherapeutic measures be instituted.

It is difficult to state mortality rates of patients suffering pneumonia secondary to Asian influenza because of the problems of reporting in foreign countries. Differences in sanitation, nutrition, and medical care and other features in foreign countries make it hazardous to compare mortality rates with those anticipated in the United States. However, pneumonia appears to develop mainly in infants and in the aged, and most of the pneumonia deaths occurred in these groups.

The Committee endorses the policy of the American Hospital Association, which holds that hospitalization should be limited to cases of influenza involving complications or to those with other diseases which might be aggravated by influenza.

All patients with influenza should be isolated insofar as it is convenient for good home or hospital care; every step should be taken to protect the patient from sources of bacterial infections. Certainly, during the acute stage of the influenza the patient should not be allowed to have visitors.

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

POSTGRADUATE COURSES

Information on the following postgraduate courses for practicing physicians has not appeared previously in The Journal.

An intermittent short course, **Medical Management of Digestive Disorders**, primarily for general practitioners will begin Oct. 1, 1957, at the Yale University School of Medicine, New Haven, Conn. Meeting for two and one-half hours on each of eight consecutive Tuesdays at a fee of $40, the course will utilize patient demonstration, lecture, panel, and open question periods as methods of education.

The Postgraduate Division of the University of Southern California School of Medicine, 2025 Zonal Ave., Los Angeles, will present at a hotel a postgraduate course Nov. 7-9, 1957, on the **diagnosis and treatment of common endocrine disorders**. This continuous 2½-day 17-hour course, primarily for general practitioners, will consist of live clinics with patient demonstrations, lectures, panels, open question periods, and audiovisual aids, at a fee of $60.

A 1-day 8-hour **dermatology clinic** primarily for general practitioners will be presented by the University of Southern California School of Medicine, Nov. 6. The teaching methods will include live clinics with patient demonstrations, lectures, audiovisual aids, and open question periods, for a fee of $25.

A six-month full-time postgraduate course, **Physical Medicine and Rehabilitation**, will begin Jan. 6, 1958, at the Highland View Cuyahoga County Hospital, Cleveland, in cooperation with Western Reserve University. This course is designed for specialists in physical medicine as well as for those physicians now in residency training in this field. It will consist of three sections. Section 1, continuing for six weeks, will include 42 hours of lecture, 24 hours of conferences, and 114 hours in wards and clinics. Each student's program will be planned individually so that he may concentrate his nondidactic training hours on those subjects most closely relating rehabilitation to his own private practice or study. Section 2, lasting 12 weeks, will include 64 hours of lecture, 40 hours of conferences, and 54 hours in affiliated facilities. Section 3, of 8 weeks' duration, will include 32 hours of lecture, 40 hours of conferences, and 168 hours in wards and clinics. Enrollment is limited to 12, at no fee. Inquiries should be addressed to Dr. Charles Long II, Department of Physical Medicine and Rehabilitation, Highland View Cuyahoga County Hospital, Harvard Road, Cleveland 22, Ohio.

An intermittent postgraduate course on radium therapy, titled **Radiology PM33**, will begin May 6, 1958, at Mount Sinai Hospital, 5th Avenue and 100th Street, New York, in cooperation with Columbia University. This solely lecture course for full-time specialists will be held on six consecutive Tuesdays, at a fee of $50.

COUNCIL ON MEDICAL SERVICE

REHABILITATION AND RESTORATIVE SERVICES

Howard A. Rusk, M.D.
and
Michael M. Dacso, M.D., New York

This is the sixth of a series of papers on various aspects of aging. Each paper has been prepared for the Committee on Aging by an authority in the field. When completed, the series will be published in booklet form.

Medical rehabilitation, or restorative medicine, as it has sometimes perhaps more aptly been called, emerged from the general background of clinical services as an answer to a long-felt need rather than as an arbitrary separation of a specialty. It is concerned with the medical care of all those who, as a result of illness or trauma, are left with a permanent impairment of their physical functions.

The broadened concept of rehabilitation has resulted in more than the creation of a new medical specialty. It has redefined and broadened the physician's responsibility to his patient. It has called upon the physician to extend his services to activities which, by conventional standards, had not been considered strictly a medical responsibility. The physician's responsibility ends only when he has restored his patient to the best and most productive life possible, as judged by two primary criteria—ability and disability.

With the recognition that chronically ill and disabled patients had problems which went beyond their physical pathology, it became evident that if these problems were not met, the results of medical care would be negated. Restorative medicine emphasizes the point of view that, in addition to the technical restoration of health, the proper utilization of restored functions is fundamentally the physician's responsibility.

This does not imply that the already overburdened physicians should involve themselves in the details of strictly social and vocational problems. This would result in the uneconomical use of a scarce and highly skilled profession. However, it is increasingly being recognized that the physician's responsibility is to know and to utilize all of the resources and coprofessional services that will lead to the optimal utilization of his patient's functional capacities. He must be captain of the team. He must write the prescriptions for social and vocational needs and see that they are properly filled just as he would for drugs or diet.

Foremost among those whose physical functioning is impaired by chronic illness or other disabling conditions are the rapidly increasing number of older people. In an effort to simplify the discussion of restoration in this large and complex group of elderly patients who could benefit from a "total approach" program without regard to etiological considerations, we have classified them into the following three empirical groups: (1) obviously handicapped patients (those with hemiplegia, arthritides, fractures, amputations, and neuromuscular diseases), (2) chronically ill patients who do not have signs of a manifest disability (those with chronic cardiac and pulmonary diseases), and (3) elderly persons who are not obviously ill but whose physical fitness is impaired.

Techniques in Clinical Diagnosis

The first step in successful rehabilitation is accurate clinical diagnosis. In dealing with physically disabled patients, it is obvious that conventional diagnostic and laboratory techniques are insufficient when it comes to evaluating physical disabilities and determining functional capabilities. Since a majority of disabled patients suffer from some involvement of the locomotor and/or neuromuscular systems, new methods of evaluating their efficiency have been added to the diagnostic armamentarium. The most important of these methods are (1) systematic testing of the strength of individual muscle groups, definitively and accurately measured, (2) determination of the range of joint motion, and

---

Professor and Chairman, Department of Physical Medicine and Rehabilitation (Dr. Rusk) and Associate Professor, Department of Physical Medicine and Rehabilitation (Dr. Dacso) New York University–Bellevue Medical Center.

Members of the Committee on Aging are Drs. H. B. Mulholland, Charlottesville, Va.; Edward L. Bortz, Philadelphia; Henry A. H[illegible], Austin, Texas; Wingate M. Johnson, Winston-Salem, N. C.; [illegible] G. Klumpp, New York; Frederick C. Swartz, Lansing, Mich.; [illegible] Cecil Watson, Omaha. Committee Staff: Mr. George W. Cooley, [illegible] Mr. Hubert B. Norton, Research Assistant.

(3) objective testing of representative activities essential for daily living (briefly summarized as activities of daily living [ADL]).

The need for an objective method for determining muscle strength has long been felt in clinical medicine. The quest for more definitive measurements continues. Until more accurate methods are developed, we must use the one that is currently accepted and generally satisfactory for clinical needs. This is the method devised by Lovett in 1932 to determine the muscle strength of his patients who had poliomyelitis. Lovett's method measures muscle or muscle group performance against a series of graded resistances as an objective expression of their strength. Accordingly the muscles can be graded as follows: zero, trace poor, fair, good, and normal. Additional subgradations allow for an acceptable accuracy in practical determination of muscle power. The most obvious shortcoming of this method is the fact that the examiner's subjective judgment cannot be excluded in applying the test resistance and evaluating the muscle response. Errors due to subjective judgment can be substantially minimized if all subsequent tests are made by the same examiner.

The objective measurement of the range within which a joint can move can be determined with much more accuracy than the strength of a muscle. The clinician who wants to learn this diagnostic method will find that the literature is rich in various techniques, all of which have advantages and disadvantages. In testing the range of a joint excursion, it is important to know that various joints have their physiological limitations determined by their anatomic structure and their relationship to the surrounding soft tissues. The accurate knowledge of these limitations is fundamental in accurate assessment.

The most recent addition to the diagnostic techniques in restorative medicine is the testing of the ADL. As previously suggested, ADL testing uses an empirical list of everyday activities without whose unimpaired performance efficient living is very difficult and sometimes impossible. ADL are customarily divided into three main groups: (1) self-care activities, (2) ambulation, elevation, and traveling activities, and (3) hand activities. The method practiced in our department calls for the testing of almost 100 different activities. The deficiencies in ADL are determined by the physician or, more usually, by the specially trained nurse or therapist. The tests are absolutely necessary for the establishment of adequate training programs. Our objective in function is not just the training of muscles or growth of muscles, but physiological exercise.

A careful analysis of the patient's general condition with the additional information gained from these functional tests will give the clinician a reliable picture of the nature and degree of the patient's physical disability. After the diagnosis has been made, an equally specific prescription for rehabilitation therapy must follow. Several reference books[1] giving definitive evaluation techniques are available.

Since documentation of the patient's improvement is important for medical and often for legal purposes, reliable recording methods are of great importance. Special charts are available for all functional diagnostic tests. Electrodiagnostic methods such as use of strength-duration curve for reaction of degeneration, galvanic tetanus ratio, chronaxy, and the most recent addition, electromyography, have greatly enhanced accurate diagnosis and evaluation of disability.

Therapeutic exercises are of primary therapeutic importance in restorative medicine. These purposeful and graded activations of certain specified muscles or muscle groups aim to make them stronger, improve their endurance and coordination, and generally improve their over-all functional efficiency. The objective in training is not just to strengthen muscles for the sake of strength, but, further and in addition to this, to increase their functional efficiency.

A basic understanding of muscle physiology is fundamental, without which therapeutic exercises should not be undertaken, just as no drug should be prescribed without a precise knowledge of its pharmacological action. The systematic reeducation and reconditioning of the general musculature imposes extra demand on the cardiovascular and respiratory system, and, indeed, affects almost every function of the human body.

Physical Restoration

The physical restoration of the disabled elderly patient (while generally the same diagnostic and therapeutic procedures are used as for the younger age group) shows many special problems which warrant discussion. One of the major differences is that in the younger handicapped person the problem is limited to a crippling condition in an otherwise healthy body; in the case of the older patient, however, the crippling condition is superimposed on the pathology of the aging process. This, in practice, means that in the elderly patient the restoration of the physical disability can rarely be separated from definitive medical care. Consequently, the physician engaged in the physical restoration of the disabled aged must possess a broad clinical knowledge of both conventional and restorative medicine.

Since the chronically ill and disabled aged constitute an ever-increasing proportion of every clinician's practice, the responsibility for these patients can no longer be placed in the hands of a few specialists. Indeed, it is the responsibility of every practicing physician to acquaint himself with the simpler methods of restorative medicine and to apply them in his practice. A number of rehabilitation courses are being offered on the postgraduate level in the major teaching centers which in a comparatively short time equip the physician with adequate knowledge to deal with common physical disabilities. The rehabilitation centers and services supplement rather than supplant the functions of the practicing physician. As in all other fields of clinical medicine, the bulk of services must be rendered by him. Highly specialized rehabilitation centers should be utilized primarily for the severely disabled. The role of such centers in the total program of restoration is fundamental.

The goals of restorative medicine in the older groups vary from those in the younger. In rehabilitation of the young, the vocational job objective is primary. In the elderly patient, vocational rehabilitation is usually secondary. Nevertheless, the absence of a vocational goal does not minimize the value of restorative medicine for the aged. The fact that the patient who previously had functional impairment regains his self-sufficiency may very well release a younger person for gainful employment. In such cases the rehabilitation of the unemployable elderly person can well be considered as indirect vocational rehabilitation. But even more important is the restoration of dignity and self-respect.

The medical and economic significance of the aging group is being increasingly recognized. The number of restorative services for the aged, though still very small, is slowly growing. The federal government, which, through its Office of Vocational Rehabilitation, has operated a successful vocational rehabilitation program, has now recognized its share of responsibility in the rehabilitation of those who no longer could be counted on in the labor market. As a result of this recognition, the various health agencies of the government are working on plans which are primarily intended to stimulate interest and, if need be, support local activities in geriatric rehabilitation.

In some communities, without any outside assistance, old-age homes are adding rehabilitation facilities to their health services. It has been our experience that, in many communities where such services have been established, one or more of the local physicians has initiated such plans. Since this is an important public and personal health problem, the support and carrying out of such services by the physicians is not only desirable but a moral obligation. Thereby they will not only discharge a professional duty but also contribute to good public and professional relationship between the medical profession and the community. Some resources that may be used in rehabilitation planning are (1) the United States Department of Health, Education, and Welfare and its various bureaus and divisions, (2) state governmental agencies, (3) religious and various other voluntary agencies, (4) the National Committee on the Aging, New York City, and (5) special committees of the American Medical Association and state or county medical society.

Conclusions

The first objective of medical rehabilitation is to prevent or to eliminate the disability if that is possible; the second, to reduce or to alleviate the disability to the greatest extent possible; and the third, to retrain the person with residual disability to "live and work within the limits of his disability, but to the hilt of his capabilities."

One of the most important tools in management of the older patient is the beneficent use of stress. All of our lives we regulate the function of our physical, emotional, and endocrine systems with our stress reaction. In the older patient stress must still be used but in smaller doses. Continuing stimulation, whether it be social, vocational, or cultural, is the only antidote for atrophy of disuse. If this concept is to be followed, all of the community resources must be utilized—governmental, religious, voluntary, and professional. The dynamic utilization of a total restorative program as has been briefly outlined means happier, healthier, and more productive and dignified lives for our aging population.

The standard form for manual muscle testing may be obtained from the National Foundation for Infantile Paralysis, 310 E. 42nd St., New York 3. Copies of tests for "Physical Demands for *Daily Living*" may be obtained upon request from the Institute of Physical Medicine and Rehabilitation, New York University–Bellevue Medical Center, 400 E. 34th St., New York.

MEDICINE AND THE LAW

PROFESSIONAL LIABILITY INVOLVING PHYSICIANS IN FEDERAL GOVERNMENT SERVICE

This is the 15th in a series of articles dealing with medical professional liability. An editorial (page 360) and a chronological résumé (page 364) appeared in The Journal, *Feb. 2. The preceding articles in this series have been published weekly in* The Journal *from Feb. 9, 1957, to April 6, and since then intermittently.*—Ed.

As part of a comprehensive study of medical professional liability, the Law Department of the American Medical Association has made a study of the particular effect of the problem on physicians in federal government service. The federal statutes and court decisions governing federal physicians' liability were studied and the Departments of the Army, Navy, Air Force, and Justice, along with the Veterans Administration and the Public Health Service, were queried concerning their experiences and views on the subject.

Undoubtedly, the federal physician is in a much more advantageous position as regards professional liability claims than is his fellow practitioner in nongovernmental practice. First of all, if a lawsuit is filed involving alleged negligence in the performance of his professional duties for the government, there is a good possibility that he will not even be named as a party defendant to the action. If the physician is named as a defendant, the government will almost always be named as a defendant also and the physician will, if he so desires, be defended by the Department of Justice at no expense to himself. Thus, he not only avoids the heavy expense of litigation, but, in having the legal, investigative, and financial resources of the United States government at his disposal, he has a definite advantage in any lawsuit. Finally, if a judgment is secured against him in a case where the United States is a co-defendant, satisfaction will undoubtedly be sought from the more solvent party—the United States government.

This unique situation in which the federal physician finds himself is due primarily to the existence of the Federal Tort Claims Act.[1]

In order to better understand the professional liability situation of the federal physician, a discussion of the Federal Tort Claims Act and the other statutes controlling this liability will be helpful. Prior to 1946, the United States government could not be sued without its consent for the negligent acts of its employees and agents. This was due to the immunity from suit inherently possessed by all sovereign governments.

Thus, many persons who were injured by federal employees while those employees were acting within the scope of their employment were without legal redress, except against the employee. Because suit could not be brought against the government to recover damages for these injuries, numerous private bills for relief were introduced into Congress. The legislators felt that they were in no position to judge the merits of these numerous bills and recognized the injustice to the citizens brought about by the government's immunity to tort suits. They, therefore, enacted the Federal Tort Claims Act. This statute waived the government's immunity to tort suits and placed the United States in a position similar to that of any other employer. The pertinent part of this statute, as amended, states:

> . . . the district courts . . . shall have exclusive jurisdiction of civil actions on claims against the United States, for money damages . . . for injury or loss of property, or personal injury or death caused by the negligent or wrongful act or omission of any employee of the Government while acting within the scope of his office or employment, under circumstances where the United States, if a private person, would be liable to the claimant in accordance with the law of the place where the act or omission occurred. [28 USCA 1346 (b)]

The effect of the passage of this act on government physicians was to make the United States liable for any negligent or wrongful acts that they might perform within the scope of their employment. As indicated earlier, in actual practice under the act, the individual physician quite often is not joined as a defendant in a professional liability suit arising out of his activities. Moreover, when a judgment is obtained under the act, any subsequent action against the physician concerning the same subject matter is barred whether the physician was a defendant in the earlier action or not.[2]

Although the Federal Tort Claims Act renders the United States amenable to suit for the tortious acts of its employees, the government's liability is based, just as is the liability of any employer, on the doctrine of *respondeat superior* (let the master answer).[3] This ancient legal doctrine holds that a master is civilly liable for the acts of his servant when the servant is acting within the scope of his employment.[4] The basic philosophy underlying this rule is that he who derives a benefit from an act which is performed by his servant should answer for any injury caused to a third person by the servant in the performance of that act.

Ordinarily, the major difficulty in applying the rule of *respondeat superior* is in determining whether the employee was acting within the scope of his employment. The test for resolving this question has been stated to be as follows: "The test of one's liability for the act or omission of his alleged servant is his right and power to direct and control his imputed agent in the performance of the causal act or omission at the very instant of the act or neglect." [5]

However, in actual practice, there has been little difficulty in establishing the government's responsibility in cases involving physicians in federal service. Since these physicians are salaried employees and since their services are performed mostly in government facilities, no serious question usually arises as to the application of *respondeat superior*. The tort act defines "scope of employment" to mean "acting in the line of duty" when applied to a member of the military or naval forces.[6] The use of this latter phrase, however, does not alter the application of *respondeat superior* to the acts of members of the armed forces,[7] nor does it in any way enlarge the responsibility of the United States for the tortious acts of members of the military.[8] Under this definition, the federal government remains liable for the acts of persons in the military service in the same manner as a private employer is liable for the acts of his employees.

Two cases delineating the government's liability where the question was raised as to whether the employee was acting within the scope of his employment are *Watt* v. *U. S.*[9] and *Dishman* v. *U. S.*[10] In the Watt decision it was ruled that the government was not responsible for the negligent operation of a government truck by a National Guard sergeant because the man's job description did not provide for his driving military vehicles and therefore he was acting outside the scope of his employment. Of course, in this case, suit could still be brought against the individual, inasmuch as it is well settled that members of the armed services remain individually liable for their torts.[11] In the Dishman case, an employee of a Veterans Administration hospital mistakenly had carbolic acid poured into his ear while being treated by a Veterans Administration physician for an ear pimple. The court held that the government was liable for the injury, as the treatment of the minor ailments of employees was authorized by VA regulations and, therefore, the physician was acting within the scope of his employment.

Even if a government physician is acting within the scope of his employment, the United States may not be liable under the Federal Tort Claims Act if the cause of action falls within certain specific exemptions to the act. For example, the act excepts from its coverage actions based on assault and battery.[12] Many professional liability suits are based on this tort, particularly those involving unauthorized operations and treatments. In *Moos* v. *U. S.*[13] the plaintiff's right leg and hip were operated on in a Veterans Administration hospital when it was his left leg and hip which required surgery. His suit for the unauthorized operation was dismissed because it was in fact an action for assault and battery.

Other important exclusions under the act are causes of action arising out of the combatant activities of the armed forces [14] and causes of actions based upon the exercise of a discretionary function or duty on the part of a federal employee.[15] The combatant exclusion would seem to be of no great importance to federal physicians at this time because servicemen, as a rule, cannot bring suit under the act. It has been held, however, that a veteran was barred from bringing suit under the act for injuries received during a physical examination in a VA hospital because the examination concerned a wound received during combat and, therefore, the claim arose out of the combatant activities of the Army.[16] This decision appears even more questionable in view of a recent decision of the Supreme Court that an ex-serviceman's suit based on a negligent operation in a VA hospital is not barred merely because the injury causing the operation was received when the plaintiff was a member of the armed forces.[17]

The exclusion in the act of causes of action based upon discretionary activities has caused the courts a great deal of trouble in determining what is and what is not a discretionary act. It has been held that admitting dependents of military personnel to government hospitals is discretionary [18] and that no action will lie which is based on the refusal to admit, even when that discretion is abused.[19] Once the discretion is exercised and the patient admitted, the discretionary function ceases and the government is liable for any subsequent negligent acts.[20] Thus, it was held that the use of an anesthetic containing a harmful substance was not a discretionary act and did not fall within the discretionary exception to the act.[21]

An important case on this point decided last year is *Fair* v. *U. S.*[22] In this case, an Air Force officer was detained for a psychiatric examination after he had threatened the life of a student nurse. The post provost marshal was alleged to have promised the girl and her two detective bodyguards that he would notify them when the officer was released. He failed to do this, and when the officer was released, after a cursory examination, he killed the girl and her two guards. The government contended that releasing the officer was a discretionary act on the part of the physician. The Court of Appeals reversed the dismissal by the trial court, ruling that the recent decisions of the Supreme Court in *Indian Towing Co.* v. *U. S.* [23] and in the Eastern Airlines case[24] had expanded the coverage of the Federal Tort Claims Act so that the discretionary act exclusion now is limited to those decisions made on a policy-making or planning level. Decisions made on an operational level, such as the one in the present case, could not be used as a basis for denying a cause of action under the act even though some discretion is involved.

The Court of Appeals also stated that the Indian Towing and Eastern Airlines decisions ended any contentions by the government in Federal Tort Act cases that the acts of government employees were strictly "governmental acts" for which there can be no liability since there are no similar acts for which a private employer could be held liable. The Supreme Court has ruled, in effect, that the question of whether an act is governmental or nongovernmental has no place in federal tort cases, and that the government is liable for all activities which it does not perform with due care and which are not otherwise specifically excluded by the terms of the act itself. The practical effect of these decisions on federal physicians is to eliminate any bar to professional liability suits on the grounds that their actions were discretionary or governmental, and to have their acts adjudged strictly according to their negligent or wrongful nature.

In addition to the causes of action specifically excepted by the act itself, two major groups of claimants are generally barred from bringing federal tort actions. They are civilian government employees covered by the Federal Employees Compensation Act[25] and members of the armed services. At one time, a government employee had an election between proceeding under the Tort Act or the Federal Employees' Compensation Act.[26] However, in 1949 Congress amended the latter act so as to make it the exclusive method of compensation for a civilian employee killed or injured "while in the performance of his duty."[27] Whether this exclusive remedy provision will particularly affect professional liability suits by civilian employees is not clear. In *Dishman* v. *U. S.*, *supra*, the District Court held that a Veterans Administration employee could bring a federal tort action based on the negligence of a government physician in treating his ear because the original cause of the suit, an ear pimple, was not incurred in the performance of his duty and therefore the employee's claim was not governed by the Federal Employees Compensation Act. It would follow from this decision that the great majority of ailments of civilian employees would not be exclusively controlled by the Compensation Act. However, very few cases have been found involving claims under the Tort Act by civilian employees against government physicians. This would indicate either that these claims are being handled under the Compensation Act or that very few civilian employees are being treated by government physicians.

If federal tort suits by civilian employees are barred by the Compensation Act, it would appear to increase the possibility of suits by the employees against the physicians as private individuals. The United States could not interevene and make itself a party in such a suit against a government physician as a private individual. The same danger of suit against the physician personally exists where pension or compensation benefits are being paid by the government to an individual, who is not a serviceman, for injuries received as a result of medical treatment. Such compensation may be used by the government to reduce the damages awarded the injured party in any subsequent federal tort action.[28] If this dimunition in damages would be substantial, the injured party might well elect to sue the physician individually, as the physician could not use the payments by the government to reduce the *damages collected from him.*

As mentioned above, it has now been clearly decided by the Supreme Court that members of the armed services and their representatives cannot bring suit against the government for injuries or death sustained by a serviceman while on duty. Previously there was some confusion on this question among the various federal circuits, and the decision of the Supreme Court in *Brooks* v. *U. S.*[29] did not clarify the situation. There it was held that a serviceman on furlough could sue the government under the Tort Act for injuries arising out of a collision with an Army truck.

In 1950, the question of the serviceman's right to sue was definitely settled in *Feres* v. *U. S.*[30] This opinion actually embraced three cases. One, *Jefferson* v. *U. S.*,[31] involved a suit by a veteran who had had a towel left in his stomach during an operation which he underwent while still in the Army. Another case, *Griggs* v. *U. S.*,[32] concerned an Army officer who died after surgery and treatment in an Army hospital. The Feres case involved an Army officer who had died in a barracks fire. The Court held that none of these claims could be brought under the Federal Tort Claims Act because the injured parties were all servicemen on duty at the time of their injury or death. The opinion stated that members of the armed forces have been financially provided for by the government in many different ways and that traditionally members of the military could not sue the government for injuries received while on duty. Furthermore, to allow servicemen to sue for every real or fancied wrong would bring chaos to the order and discipline of the military services.

While this decision has been severely criticized, it does clearly establish the status under the Federal Tort Claims Act of the largest group to which the government physician renders his services. The Feres decision has caused the dismissal of numerous professional liability suits involving government physicians and members of the armed services.

Although it might be expected that the denial to servicemen of Federal Tort Claims relief would cause additional suits to be filed against government physicians as individuals, there is no indication of any such trend. The Department of the Air Force states that no Air Force physician has ever had to pay any judgment arising out of a professional liability claim. The information received from the other services would indicate a similar situation. Apparently then, the Feres rule has aided the government physician's liability situation rather than damaged it.

In order to determine the actual experiences of the various governmental agencies with professional liability claims, requests for this information were sent to the Departments of the Army, Navy, Air Force, and Justice, the Veterans Administration, and the United States Public Health Service.

In the 10-year period from 1947 to 1957, the Department of the Army reported 36 suits involving alleged medical professional liability. This identical number of suits was also reported by the Navy. It is the largest number reported by any governmental service. This, of course, is to be expected, considering the large number of persons under Army and Navy jurisdiction and their extensive medical programs.

Of the 36 actions reported by the Army, 7 resulted in compromise settlements, 2 resulted in judgments for the claimant, 6 are still pending, and 21 were either decided in the government's favor or withdrawn. Of the seven cases settled, only three were for substantial amounts. Two actions, settled respectively for $47,500 and $30,000, involved the administration of caudal anesthetics at childbirth. The third, resulting in a $10,000 payment, involved a transfusion of improperly labeled blood. The two suits ending in judgments against the United States resulted in substantially higher payments. The Cannon case,[33] in which an operation for varicose veins was performed in a negligent manner, resulting in extensive additional surgery, ended in a verdict for $123,904. In the Grigalauskas decision,[34] where undiluted lactated Ringer's solution was mistakenly applied to a newborn infant, the verdict was for $84,650. Included in the 36 actions involving Army physicians were 11 based on alleged negligence in performing surgery, 5 involving allegedly negligent blood transfusions, 3 based on the administration of medicaments, and 2 each involving caudal anesthetics, failure to diagnose breast cancer, alleged negligent handling of heating devices, and psychiatric confinements.

Of the 36 cases reported by the Navy Department, 13 are still pending, 14 have been decided in the government's favor, 3 resulted in verdicts for the plaintiffs, and 6 were settled for varying amounts. The two largest compromise payments, for $40,000 and $30,000, involved the death of a patient following childbirth and the paralysis of a foot and ankle following a knee operation. It has been reported,[35] however, that the Department of Justice recently announced that it settled a suit involving the administration of a spinal anesthetic in a naval hospital for $175,000. This would be the largest amount awarded a claimant in a professional liability suit involving a government physician. Six of the suits reported by the Navy Department involved medication, four each had to do with diagnosis and anesthesia, and three each involved surgery and burns from heating devices.

The Air Force states that it has had 12 suits involving its physicians since 1950. Of these, six resulted in settlements or judgments in favor of the claimants, one was dismissed by the District Court, and five are still pending. Except for two cases involving foreign matter being left in the patient after surgery, these 12 cases involve no common act of alleged negligence.

Although the Veterans Administration did not supply any statistical data concerning professional liability suits involving its physicians, it did state that these suits generally reflect alleged improper diagnosis, negligence in the performance of surgical procedures, and errors committed in the administration of medicine or drugs. Their letter also noted that in only two or three cases have Veterans Administration physicians been named as co-defendants. Usually, the suits have been against the United States as sole defendant.

The surgeon general of the Public Health Service reports 15 suits involving physicians employed by the Public Health Service during the period July 1, 1952, to June 30, 1956. Five of these are pending, four have been decided in favor of the government, and the remaining six resulted either in judgments for the plaintiffs or in compromise settlements. These latter six actions resulted in the payment of $114,000 by the government, an average of $14,000 per case. Altogether, $480,000 was sought by the plaintiffs in these suits. Except for two cases involving alleged negligence during surgery, no common acts of negligence are found among the Public Health Service suits.

Conclusions

The professional liability situation of the government physician appears much brighter than that of his fellow practitioner in nongovernmental practice. The persons to whom the government physician renders medical services have many choices of recourse for injuries received during treatment. Some course other than seeking money damages from the physician himself is usually chosen. Through the Federal Tort Claims Act, the Federal Employees Compensation Act, and the various veterans statutes, a claimant can be fairly compensated by the United States government without involving the physician in litigation. The reports of the governmental departments contacted in this study indicate that in the armed forces and the United States Public Health Service there are relatively few serious professional liability cases arising out of the medical activities of physicians working for such agencies.

ARTIFICIAL INSEMINATION

This is the fourth in a series of six articles dealing with the necessity for and proper format of certain medicolegal forms. The subjects to be covered are (1) consent to operations and other medical procedures; (2) patient's right to privacy; (3) confidential communications and records; (4) artificial insemination; (5) the physician-patient relationship; and (6) autopsy.

This material has been prepared and will be published in book form by the Law Department of the American Medical Association under the title "Medicolegal Forms with Legal Analysis." The book will include extensive legal citations and a substantial number of additional forms which have not been included in this series of articles.—Ed.

If recent literature is to be believed, physicians are more and more being asked to perform, and are performing, artificial insemination procedures. Artificial insemination may be performed using the semen of the woman's husband or the semen of a donor who is, or should be, unknown to both the woman and her husband and who, conversely, should not know either of them. If the semen of the woman's husband is used the procedure is known as AIH (artificial insemination homologous); if the semen of some other man is used it is known as AID (artificial insemination donor). In all probability, AIH poses few, if any, legal problems inasmuch as the child is actually their biological offspring.

In *Doornbos* v. *Doornbos* an Illinois trial court said that AIH "is not contrary to public policy and good morals, and does not present any difficulty from the legal point of view." But of AID, the court said, "Heterologous Artificial Insemination . . . with or without the consent of husband, is contrary to public policy and good morals, and constitutes adultery on the part of the mother. A child so conceived is not a child born in wedlock and therefore illegitimate. As such it is the child of the mother and the father has no right or interest in said child." The state's attorney appealed only from the decree of divorce which was silent as to the legitimacy of a child born by heterologous artificial insemination, and did not appeal from a declaratory judgment wherein the question of legitimacy was determined. The court on appeal held that since the child was not represented in the legitimacy proceedings, the child was not bound by the adverse judgment determining him to be illegitimate. The appeal was dismissed. In a similar New York case, *Strnad* v. *Strnad*, a child resulting from AID, which had been performed with the consent of the husband, was held not to be illegitimate and the husband was given the right of visitation. It was stated, as dictum, in a Canadian divorce case that artificial insemination, without the consent of the husband, is adultery on the part of the wife.

The problems of legitimacy, inheritance, etc., primarily concern the parents and the offspring rather than the physician who performs the artificial insemination. The performance of artificial insemination does, however, create hazards for the physician which necessitate an adequate agreement between him and his patient. As is the case with other medical procedures, the physician cannot free himself from the obligation to use due care and skill in the performance of the procedure itself. The agreement with the parties should cover the points set forth below. 1. The wife should consent in writing to the procedure because otherwise its accomplishment would constitute an assault and battery. 2. The written consent of the husband should be obtained because the procedure seriously affects and involves the marital relationship. 3. The donor should consent in writing to the unrestricted use of the semen he supplies and should certify that he will make no effort to ascertain the identity of the husband and wife involved. 4. Although the possibility of suit by her is remote, the written consent of the donor's wife to the giving of the semen may also be desirable inasmuch as her marital interests are affected. 5. The physician should have permission to use his own best judgment in selecting the outside donor. The law has not as yet delineated the responsibilities of the physician on this score, but it would seem that he would be obligated to use reasonable care in selecting a healthy donor, who has no knowable transmissible disease. There are certain other desirable precautions which the physician should observe. The physician should establish to his own satisfaction that, from the medical point of view, the husband is sterile. Where possible, the semen used should be "pooled" and include semen of husband and donor. The use of such "pooled" specimen would give rise to the legal possibility that the husband was the father, or at least it would make it more difficult to prove that he was not the father where the donor is of the same blood group. The physician should make certain that the identity of the donor is kept from the husband and wife and their identity kept from the donor. However, the physician should have a record, preferably in code form and open only to himself, of the identities of the donor and the husband and wife, in the event that such information later becomes necessary in defending litigation.

It cannot be too strongly emphasized that obtaining the consent and observing the precautions mentioned above may have a bearing only upon the physician's civil responsibilities. No court decisions and no statutes have as yet spelled out any criminal aspects of artificial insemination. If the procedure should be held to be a criminal offense, in all probability it would be the physician, rather than the donor, who would be regarded as the guilty party. The donor has no control over the use of the semen; it is the physician who, by his own voluntary act, has actually interfered with the wife's reproductive faculties and caused the birth of any child that may result. If the performance of artificial insemination should be held to be a criminal offense, the fact that the patient consented may not be a defense to the physician. It has generally been held that consent to perform a criminal act is a nullity.

Since neither the courts nor the legislatures have as yet spelled out the physician's civil or criminal position with respect to the performance of artificial insemination, he should be insistent upon the greatest protection possible and should preserve adequate records in the event that any difficulties arise.

FORM 1.—*Agreement for Artificial Insemination*

The undersigned,..............................., and..........................., both being of legal age, represent that they were married on ....19.........., at.., and that they have continuously cohabited together as husband and wife since the aforementioned date. The undersigned request and authorize Dr..., and such assistants as he may designate, to inseminate the wife, artificially, subject to the following conditions and agreements.

1. The insemination may be repeated at times recommended by the physician until the wife becomes pregnant.

2a. The physician shall use only semen collected from the husband.

2b. The physician shall use pooled semen from the husband and a donor or donors whose name or names shall not be required to be disclosed to the husband and the wife.

2c. The physician shall use the semen of a donor or donors whose name or names shall not be required to be disclosed to the husband and the wife.

3. The husband and the wife agree to cooperate fully with the physician in all phases of this procedure and never to seek to discover the identity of any unknown donor or donors.

4. The husband and the wife have been fully informed by the physician of the hazards, risks and possible consequences involved, and nevertheless, individually and jointly agree to hold the physician and such assistants whose services he may utilize, and the donor or donors, free and harmless for any claims, demands, or suits for damages for any injury or complications whatever which may result directly or indirectly from any treatment or artificial insemination performed pursuant to this agreement.

Signed..(husband)

Signed..(wife)

Date......................................

Accepted:

Signed..M.D.

Witness..

Note. Use the applicable paragraphs under 2. Paragraphs 3 and 4 would also be altered in cases where the husband is the donor.

FORM 2.—*Application to Serve as a Donor of Semen*

Date......................................

To Dr..:

1. I hereby offer my services as a donor of semen with the understanding that if I am accepted to serve in this capacity you shall not reveal my identity to any recipient nor shall the identity of any recipient be disclosed to me, except as may be required by legal or judicial process.

2. I represent that to the best of my knowledge and belief I was born of exclusively..
(Caucasian, Negroid, etc.)
ancestry, that my religion is..,
and that the nationality of my ancestry is predominantly

....

3. I represent that I am in good health, that I have no communicable disease, that I am not now nor have I ever suffered from any physical impairment or disability, whether inherited or as a result of any disease or ailment, except as follows:..

....

4. I represent that I am not now nor have I ever been afflicted with syphilis or any other venereal disease, nor any mental ailment or emotional disturbance, except as follows:

....

....

5. I represent further that none of my grandparents, parents, brothers, or sisters, if any, children, if any, nor their lineal descendants have, to the best of my knowledge and belief, ever been afflicted with insanity or mental illness or any inherited physical disabilities or disease, except as follows:

....

....

6. For the purpose of determining whether I am acceptable as a donor of semen, I hereby consent to a physical examination of myself by you or any other physician whom you may designate, and the taking of blood and other body fluids as may be required for laboratory examination.

I HEREBY SWEAR THAT ALL OF THE REPRESENTATIONS MADE BY ME IN THE FOREGOING PARAGRAPHS ARE TRUE AND CORRECT.

Signed..

Witness..

FORM 3.—*Consent of Wife of Donor*

To Dr..:

1. I have read the above application to serve as a donor of semen which my husband has executed, and to the best of my knowledge and belief the representations therein contained are true and correct.

2. I understand that if my husband is accepted by you as a donor, it is your intention to use such semen for purposes of artificial insemination, but *not* with respect to myself.

3. I understand further that artificial insemination is a medical procedure intended to cause pregnancy of a woman through the use of semen introduced by means other than sexual intercourse.

4. Knowing full well that in serving as a donor of semen, my husband may become the father of a child or children of which I am *not* the mother, I nevertheless consent to the performance of such services by him.

5. To induce you to accept my husband's services as a donor of semen, I agree that I shall neither directly nor indirectly attempt to discover the identity of any recipient, and I further agree not to bring any action in law or in equity, or otherwise, against you or my husband as a consequence of any services which my husband may render as a donor of semen.

THIS CONSENT AND THE AGREEMENTS THEREIN CONTAINED ARE GIVEN FREELY AND VOLUNTARILY.

Signed..

Witness..

MEDICAL NEWS

CALIFORNIA

State Medical Election.—The following officers of the California Medical Association have been installed: president, Dr. Frank A. MacDonald, Sacramento; president-elect, Dr. Francis E. West, San Diego; secretary, Dr. Albert C. Daniels, San Francisco; and editor, Dr. Dwight L. Wilbur, San Francisco.

Appoint Director of Medical Education.—St. Mary's Hospital, San Francisco, has appointed a full-time director of medical education to supervise the intern-resident training program and the program of staff education. He is Dr. George H. Reifenstein, who completed his duties as chief of cardiology, U. S. Naval Hospital, Oakland, Sept. 1. Dr. Reifenstein is a diplomate of the American Board of Pathology and the American Board of Internal Medicine. The purpose of employing a full-time director of medical education is to continue to improve the program which St. Mary's has established and which has helped to maintain more than its full complement of internes and residents.

Dr. John B. de C. M. Saunders, dean, University of California Medical School, San Francisco, will continue his lectures in anatomy, and Harold Harper, Ph.D., consultant in biochemistry at St. Mary's, will continue his lectures in basic biochemistry as applied to medicine.

GEORGIA

Appoint Mental Hygiene Director.—Dr. Trawick H. Stubbs has been appointed director of the mental hygiene division, Georgia Department of Public Health. Dr. Stubbs earned a master of public health degree from the Harvard School of Public Health, Boston. He has served as a regular officer with the U. S. Public Health Service, as associate professor of preventive medicine, and assistant dean, Emory Medical School, Atlanta, and as dean of the University of Missouri Medical School, Columbia. He is also former assistant director of the Rhode Island Department of Social Welfare. His work in Georgia will involve development of an intensive treatment program for the mentally ill through the general hospitals in the state. Governor Marvin Griffin recently appropriated $75,000 per quarter to begin a screening and short-term treatment program for the mentally ill of moderate means to help relieve the patient load of Milledgeville Hospital.

ILLINOIS

Chicago

Personal.—Dr. G. Howard Gowen, who for many years has been deputy director of the Division of Hospitals and Chronic Illness for the Illinois State Department of Health, has resigned to become chief of the Division of Health and Welfare in the U. S. Operations Mission in Santiago, Chile.

Research Grants Available.—The Chicago Heart Association has announced the availability of grants-in-aid made for the fiscal year, July 1 to June 30 inclusive, which may be renewed upon application and annual review, if funds are available. Any established researcher in the Chicago area connected with a reputable research institute is eligible provided his research is related to the heart. Completed applications are due Nov. 1 to be effective July 1. For information write the Chicago Heart Association, 69 West Washington St., Chicago 2, Ill.

Dr. Thorek Honored.—Dr. Max Thorek, founder of the International College of Surgeons, has been honored by the French government with the award of Commander of the Legion of Honor for his contributions to surgery and his work in the formation and growth of the college, "creating a better understanding and scientific cooperation among surgeons of the world."

Dr. Thorek founded the International College of Surgeons 22 years ago at Geneva, Switzerland. Since then it has established chapters in 42 countries, excluding Russia and its satellites, and has a membership of 12,000 surgeons. Dr. Thorek serves as secretary-general of the college and as editor of its journal.

INDIANA

State Medical Association Meeting.—The 108th annual convention of the Indiana State Medical Association will be held Oct. 6-9 in the French Lick-Sheraton Hotel, French Lick. A panel discussion, "What's New—Important Developments," will be conducted by Dr. Walter L. Portteus, Franklin. Dr. Elton R. Clarke, Kokomo, president of the association, will present an address at the president's dinner. The program includes the following topics by out-of-state speakers:

Work Classification of the Cardiac, Dr. Herman K. Hellerstein, Cleveland.
Office Gynecology, Dr. William J. Dieckmann, Chicago.
The Prediction and Prevention of Coronary Heart Disease, Dr. John W. Gofman, Berkeley, Calif.
Surgical Management of Benign Conditions of the Large Bowel, Dr. Henry K. Ransom, Ann Arbor, Mich.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Medical Management of Benign Lesions of the Large Intestine, Dr. J. Arnold Bargen, Rochester, Minn.
Electrocardiogram in Coronary Disease, Dr. George E. Burch, New Orleans.
Epidemiology of Influenza, Dr. Fred M. Davenport, Ann Arbor.
Medical Problems in Disaster Management, Col. Joseph R. Shaeffer, M.C., Washington, D. C.
Tumors and Cysts of the Head and Neck, Dr. Albert C. Furstenberg, Ann Arbor.
Modern Physiological Concepts in the Therapy of Pregnancy Toxemia, Dr. Milton L. McCall, New Orleans.

Dr. Virginia Apgar, New York City, will speak at the luncheon meeting. Scientific and technical exhibits are scheduled, and a special ladies' program is planned. Entertainment includes the president's reception, Oct. 9. For information write the Indiana State Medical Association, 1021 Hume Mansur Building, Indianapolis 4, Ind.

Society News.—The following officers of the Indiana Academy of General Practice have been installed: Dr. James L. Lamey, president, Anderson; Dr. Floyd A. Boyer, president-elect, Indianapolis; Dr. Edward C. Voges, vice-president, Terre Haute; Dr. Frances T. Brown, treasurer, Indianapolis.

KANSAS

Clendening Lectureship.—Dr. Ralph H. Major, professor emeritus of the history of medicine, University of Kansas School of Medicine, Kansas City, presented the eighth course in the series of the Clendening lectureship at the university recently on "Disease and Destiny" and "Logan Clendening." The lectureship was established in 1949, by Mrs. Clendening in memory of her husband the late Dr. Logan Clendening.

School Health Symposium.—The University of Kansas Medical School in cooperation with the School of Education of the University of Kansas will hold its third annual symposium on school health Oct. 10. A panel discussion, "Effective Cooperation for School Health: The Physician and the Educator," will be moderated by Fred V. Hein, Ph.D., consultant in health and fitness, American Medical Association, Chicago. The program includes the following topics and speakers:

The Physician Views School Health, Dr. Conrad M. Barnes, chairman, committee on school health, Kansas State Medical Society.
What Young People Are Like; What Young People's Needs Are; What Methods Work with Young People; What Young People Want to Know About, Dr. J. Roswell Gallagher, chief, adolescent unit Children's Medical Center, Boston.
Health Teaching in Today's Schools, Dr. Hein.
Meeting the School and Health Needs of the Adolescent, Dr. Gallagher.

Discussion groups including physicians, school representatives, and industrialists are scheduled. Luncheon speaker will be Dr. E. Ungerleider, director of medical research, Equitable Life Insurance Society of the United States. For information write University of Kansas Medical Center, Rainbow Boulevard at 39th Street, Kansas City 12, Kan.

MICHIGAN

Society News.—Newly elected officers of the Detroit Roentgen Ray and Radium Society are: president, Dr. W. George Belanger; vice-president, Dr. Ivor D. Harris; and secretary-treasurer, Dr. Joseph O. Reed Jr., 3825 Brush St., Detroit.

Personal.—Dr. Henry K. Ransom, a native of Jackson, has been named acting chairman of the surgery department, University of Michigan Medical School, Ann Arbor, following announcement of the retirement of Dr. Frederick A. Coller, chairman of the department for 27 years. Dr. Ransom was promoted to professor of surgery in 1950 and since has worked under Dr. Coller. Since 1934 Dr. Ransom has been visiting surgeon at St. Joseph Mercy Hospital in Ann Arbor.——Walter L. Mallmann, Ph.D., professor of microbiology and public health at Michigan State University, will make a study in the eastern Mediterranean countries for the World Health Organization. Professor Mallmann will survey the food in the countries from a public-health aspect. Besides his three-month study, he will also visit various laboratories in Europe.

NEBRASKA

Personal.—Dr. Harle V. Barrett has been appointed acting director, department of preventive medicine and public health, Creighton University School of Medicine, Omaha, in the rank of assistant professor. Dr. Barrett is certified by the American Board of Preventive Medicine. His teaching experience includes Oklahoma Baptist University, Kansas State College, St. Joseph's School of Nursing in Ponca City, Oklahoma, and the University of Oklahoma School of Medicine, Oklahoma City. He has served as preventive medicine officer at Fort Ord, Calif. Pusan, Korea, and Fort Sill, Okla.

Dr. Walske Appointed Acting Director.—Dr. Benedict R. Walske has been appointed associate professor of surgery and named acting director, department of surgery, and head of the surgical specialties of the Creighton University School of Medicine, Omaha, replacing Dr. Harry H. McCarthy, who will devote more of his time to private practice and research. Dr. Walske has been chief of the surgical services at the Veterans Administration Hospital in Lincoln since 1951. He is certified by the American Board of Surgery and the American Board of Thoracic Surgery. He is a member of the American College of Surgeons, the American College of Chest Physicians, and the Lancaster County Medical Society.

NEW YORK

Cardiovascular Research Project.—A study of the relationship between hardening of the arteries in the heart in the human being and his living activities and other environmental factors is being developed in the Albany area is a cooperative venture of the State Health Department and Albany Medical College. It is based on a pilot study made last year by Dr. William G. Beadenkopf, assistant director of the Bureau of Epidemiology and Communicable Disease Control of the State Health Department, and Dr. Assaad Daoud, assistant professor of pathology, Albany Medical College.

The degree of atherosclerosis in all adults on whom autopsies are performed at Albany Hospital will be determined, then information will be sought on the way of life—habits of eating, drinking, working, and recreation—of each person autopsied. More than 1,600 individuals will be included in the study. The State Health Department has contracted with the college for the expenditure of $56,500 for the study during the coming year.

General Practitioners Scientific Assembly.—The ninth annual scientific assembly of the New York State Academy of General Practitioners will be held Oct. 21-23 at the Barbizon-Plaza Hotel, New York City. An address will be given by Dr. Richard P. Bellaire, president of the academy. The program will include the following topics and moderators:

Atomic Medicine, Dr. Joe W. Howland, Rochester.
Geriatric Problems, Dr. Benjamin Boshes, Chicago;
Teaching Symposium on Dislocations and Fractures (Closed TV Circuit), Drs. Samuel A. Garlan and Jeff J. Coletti;
Newer Chemotherapeutic Aids in Nervous and Mental Disorders, Dr. Harold W. Lovell, New York;
Obstetrical Program for the GP, Dr. Gordon W. Douglas, New York City.

Audience participation discussions will follow morning and afternoon sessions. Dr. G. Gordon Bell, director of the Bell Clinic, Willowdale, Ontario, Canada, will speak on alcoholic disorders, Oct. 23. Following the formal program, special visits to the Institute for Rehabilitation Medicine and the Brookhaven Institute and Atomic Research Laboratory at Long Island are scheduled. For information write the New York State Academy of General Practitioners, 84 Main St., Binghamton, N. Y.

Poison Control Centers.—Wallet-sized cards giving the location and telephone number of each of the five poison control centers in New York State are being distributed to each physician in Upstate New York. Dr. Herman E. Hilleboe, state health commissioner, has pointed out that about 1500 deaths occur from accidental poisoning each year in the United States. Of these, one-third occur in children under 5 years of age. Because of the hundreds of new medicinal and household products appearing on the market each year, a network of five poison control centers has been established with the assistance of the New York State Health Department. The centers answer inquiries from physicians concerning the ingredients of drugs and household supplies and advise on appropriate treatment methods. Twenty-four hour emergency service is available. Only emergency advice is given in answer to inquiries from the general public, with the suggestion that a physician be called at once. The centers are located at Albany Hospital, Albany; Children's Hospital, Buffalo; Strong Memorial Hospital, Rochester; City Hospital, Syracuse; and the New York City Health Department.

Personal.—Dr. John C. McClintock, associate professor of surgery, Albany Medical College, has received an invitation to create and display a scientific exhibit on thyroid cancer at the seventh annual International Cancer Congress in London, England, next summer. The congress, which is held under the auspices of the International Union Against Cancer, will be staged in London's Royal Festival Hall July 6-12, 1958.——Dr. William S. McCann, emeritus Dewey Professor of Medicine, University of Rochester School of Medicine and Dentistry has been named a visiting professor at the Sloan Institute of Hospital Administration, Cornell University, Ithaca.

Symposium on Diabetes.—"Fat and Diabetes" will be the topic of the fifth Symposium Day on Diabetes Mellitus to be held Oct. 12th in New York City at the Hunter College Playhouse Auditorium. The symposium is sponsored by the Clinical Society of the New York Diabetes Association, and *advance registration is required* for admittance. Out-of-state speakers include the following: Dr. William C. Stadie, University of Pennsylvania; Dr. Marvin D. Siperstein, University of Texas Southwestern Medical School; Drs. Margaret J. Albrink and Evelyn Man, Ph.D., Yale University School of Medicine; Dr. Robert E. Olson, University of Pittsburgh; Dr. Franz X. Hausberger, Jefferson Medical College; and Dr. Stanley Hartroft, Washington University. For information write the New York Diabetes Association, 104 E. 40th St., New York City 16.

New York City

Appoint Dean of Medical College.—Dr. Robert A. Moore, vice chancellor of the health professions at the University of Pittsburgh, has been appointed president of the Downstate Medical Center of the State University of New York and dean of the Center's College of Medicine, succeeding Dr. Howard W. Potter, who will retire. Dr. Moore has served on the faculty of Ohio State University, Western Reserve University, Cornell University and Washington University, St. Louis, where he was dean of the School of Medicine for seven years. He is a member of the National Advisory Cancer Council of the U. S. Public Health Service, a trustee of the China

Medical Board of New York, and immediate past-president and executive council member of the Association of American Medical Colleges. He has served as president of the American Association of Pathologists and Bacteriologists and of the Gerontological Society.

Compensation Medicine Program.—New aspects of health problems intensified by modern living will be presented at a one-week program, "Medical Aspects of Workmen's Compensation," to be offered Oct. 21-25 by New York University Post-Graduate Medical School and the American Academy of Compensation Medicine. Ten sessions covering the field of compensation medicine will be given by the department of industrial medicine. Problems facing physicians dealing with compensation medicine will be covered, including "The Heart in Industry"; "Medical Problems of the Older Worker"; "Tranquilizers and the Worker"; and "Radiation." Tranquilizers will be considered in the broadest sense as they affect industrial workers, white-collar employees, and the automobile driver. There will be a morning and afternoon session each day of the course which may be taken in its entirety or by individual session. For application and information write Office of the Associate Dean, New York University Post-Graduate Medical School, 550 First Ave., New York City.

Dr. Rush Appointed to Chair in Physical Medicine.—A chair for the department of physical medicine and rehabilitation of New York University College of Medicine has been created through a gift of $500,000 by the late Louis J. Horowitz, honorary trustee of New York University-Bellevue Medical Center and an original founder of the Institute of Physical Medicine and Rehabilitation. The first incumbent, for which the chair was designated and named, will be Dr. Howard A. Rusk, chairman of the department and director of the institute. In addition to the endowed chair, funds will be used to subsidize those patients who are unable to meet the cost of their care and to provide fellowship training for personnel in the rehabilitation specialties. Dr. Rusk, organized the department of physical medicine and rehabilitation in 1948.

NORTH CAROLINA

Appoint Chairman of Biochemistry Department.—J. Logan Irvin, Ph.D., has assumed the chairmanship of the department of biochemistry and nutrition, University of North Carolina School of Medicine, Chapel Hill. At the same time Dr. Irvin, who has been a member of the faculty since 1950, was promoted from associate professor to professor. Dr. Irvin returned to the university last September after completing nine months of research at the National Institutes of Health at Bethesda, Md., on the biosynthesis of proteins and nucleic acids of normal liver and liver tumors, supported by a Guggenheim Foundation fellowship. Previously he was on the faculty of the Johns Hopkins School of Medicine, Baltimore, for nine years. He is a member of the American Chemical Society, the Society of Experimental Biology and Medicine. and the American Society of Biological Chemists.

OHIO

Society News.—The Cleveland Radiological Society recently elected the following officers for 1957-58: president, Dr. Delbert A. Russell; vice-president, Dr. Thomas Knickerbocker; and secretary-treasurer, Dr. Frederick A. Rose. 2065 Adelbert Road, Cleveland 6.

PENNSYLVANIA

Philadelphia

Personal.—Dr. Philip S. Barba, associate professor of pediatrics, Graduate School of Medicine, University of Pennsylvania, has been appointed to serve on the President's Citizens Advisory Committee on the Fitness of American Youth.——Dr. James L. A. Roth, associate professor of physiology and gastroenterology, University of Pennsylvania Graduate School of Medicine, received an honorary degree of doctor of science at the recent commencement exercises of Carthage College, Carthage, Ill.

TEXAS

Society News.—Dr. Jacobus D. McCulley, Houston, was recently elected president of the Texas Society of Anesthesiologists. Other officers include Dr. Milton M. Rosenzweig, San Antonio, president-elect; Dr. David O. Johnson, Austin, vice-president; Dr. Randle J. Brady, Houston, secretary-treasurer; and Dr. Lawrence W. Schuhmacher, Houston, program chairman.——Dr. Truman G. Blocker Jr., Galveston, was recently elected president of the Texas Society of Plastic Surgeons. Other officers are Dr. Sidney Hardy, Houston, vice-president, and Dr. Steve R. Lewis, Galveston, secretary-treasurer.

Division of Medical Sociology.—A division of medical sociology has been established in the department of preventive medicine and public health, University of Texas Medical Branch, Galveston. In addition to conducting research and teaching in the realm of socio-environmental aspects of health and illness, the division operates jointly in such specialties as psychiatry, nursing and medical education, and administration. Research projects in areas such as industrial health, social epidemiology of mental disorders, tuberculosis, and alcoholism are currently under way. E. Gartley Jaco, Ph.D., will serve as director, with the initial staff composed of Norman G. Hawkins, Ph.D., and Sam Schulman, Ph.D., as assistant professors of medical sociology.

WASHINGTON

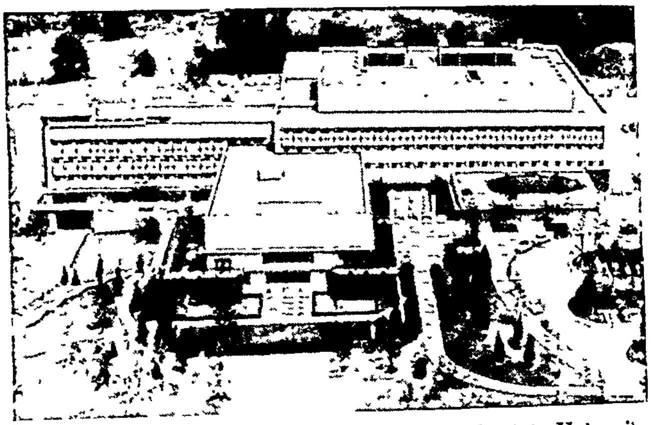
Appoint Radiology Department Head.—Appointment of Dr. Melvin M. Figley as head of the University of Washington Medical School's department of radiology has been approved by the board of regents. The regents also reestablished a department of oral pathology in the School of Dentistry. Dr. Figley will be the first permanent head of the radiology department. His appointment is effective June 1, 1958. Currently an assistant professor of radiology at the University of Michigan, he is also a consultant at the Ann Arbor Veterans' Administration Hospital. He has been a member of the Michigan faculty since 1950. Dr. Figley holds a five-year $30,000 Markle Foundation fellowship, and this year he was awarded research grants by the Michigan and American Heart associations. His research interests lie in the field of angiography.

Annual Symposium on Heart Disease.—The ninth annual symposium on heart disease, sponsored by the Washington State Heart Association and the Washington State Department of Health, will be held at the University of Washington Medical School Auditorium Oct. 4-5. Speakers include Dr. Herman Hellerstein, Cleveland; Dr. Robert P. Grant, Bethesda, Md.; Henry Longstreet Taylor, Ph.D., Minneapolis; Dr. Julius H. Comroe Jr., Philadelphia; and Dr. Paul Dudley White, Boston. Themes of the symposium will be "Changing Attitudes About Coronary Disease" and "Disorders of the Heart and Lungs." The speakers will also conduct panel sessions and discuss questions from the audience. For information write Dr. Robert A. Bruce, Chairman, Annual Symposium, Planning Committee, 3121 Arcade Building, Seattle 1, Wash.

WEST VIRGINIA

State Medical Election.—The following officers of the West Virginia State Medical Association have been elected for 1957-1958: president, Dr. Charles A. Hoffman, Huntington; president-elect, Dr. George F. Evans, Clarksburg; vice-president, Dr. Jacob C. Huffman, Buckhannon; treasurer, Dr. Thomas Maxfield Barber, Charleston (reelected). The 91st annual meeting of the association will be held at The Greenbrier, White Sulphur Springs, Aug. 21-23, 1958.

Dedicate Basic Sciences Building.—The Basic Sciences building of the West Virginia Medical Center, Morgantown, will be dedicated Oct. 5. Principal speaker at the ceremony will be Dr. William S. Middleton, chief medical director for the Veteran's Administration and former dean of the University of Wisconsin School of Medicine. The building is the second unit in the center constructed toward the expansion of the present two-year school to a four-year medical program and development of schools of nursing and dentistry. The College of Pharmacy will move from the university campus to the medical center. The basic sciences building consists of a central core, measuring 225 by 225 feet with five wings extending an additional 100 feet to the north, east, and west. The core is five stories high and contains lecture rooms, laboratories, and other teaching facilities. Located on the second, third and fourth floors are facilities for teaching anatomy, biochemistry, microbiology, pathology, pharmacology, physiology, and public health and preventive medicine, plus specialized research equipment. The School of Dentistry occupies the first floor of the core. The wings contain the schools of nursing and pharmacy and the administrative offices, the library, main auditorium, and a lounge, lockers, post office, bookstore, and food services. Construction of the 500-bed teaching hospital, which will be connected to the basic sciences building, is underway, and completion is scheduled within three years.



New Basic Sciences Building at West Virginia University, Morgantown.

GENERAL

Coronary Heart Disease.—The Metropolitan Life Insurance Company Information Service has reported that coronary heart disease, "the commonest form of heart disease today," is least frequent among young married women, among persons living in the rural part of the southern states, and among those who have had no history of premature death or occurrence of heart disease in the family. A study of recorded mortality from heart disease by statisticians of the insurance company reveals variations according to age, sex, weight, race, marital status, geographic region, and other factors. Up to age 45, the death rate from heart disease runs up to 6.6 times as high for white men as for white women. The ratio decreases progressively with advance in age, until at age 85 and over the rates for the two sexes among white persons are about the same. Among nonwhites the sex differences in the death rate are much smaller and do not vary much with age. Heart disease death rates are significantly higher for the widowed, the single, and the divorced than for the married. Studies have shown that people who are overweight are more likely to suffer fatal attacks of heart disease. When overweight is coupled with slight or moderate elevation of blood pressure, the chances of such an attack are greatly increased. The heart disease death rate is lowest in the east south central region and highest in the middle Atlantic region.

Public Health Development Program.—The American Public Health Association is initiating a long-range technical development program to help communities with new and changing health problems. According to Dr. Reginald M. Atwater, executive secretary of the association, in some important areas of public health methods and standards have remained virtually unchanged "since the horse-and-buggy era." Initial concentration will be in eight areas: radiological health, accident prevention, mental health, chronic disease and rehabilitation, child health, environmental health, medical care administration, and public health administration. A committee of experts in each area will develop policy statements, write operating manuals, conduct field studies, surveys, and demonstrations, and consult with state and local health authorities and agencies. To coordinate the program a technical development board has been appointed. Chairman is Dr. Martha M. Eliot, former chief of the U. S. Children's Bureau and now professor of maternal and child health at the Harvard School of Public Health, Boston. Initiation of the technical development program is the first step in a three-year expansion and reorganization program for the 85-year-old professional society. The total program will require a $250,000 increase in annual operating budget, to be reached by 1960. The Rockefeller Foundation has made a grant of $150,000 to help finance new activities during the developmental period.

International Seminars in Mental Health.—The Postgraduate Center for Psychotherapy, New York City, will initiate a series of international seminars in the field of mental health by presenting Dr. W. Grey Walter, British neurophysiologist, who will speak on "Brain Behavior," at an open meeting at the New York Academy of Medicine at 8:00 p. m., Oct. 23 Dr. Walter will lead two other seminars, on Oct. 20 and 31, respectively, when the subjects will be "The Physiology of Personality" and "The Cybernetic Approach to Mentality and Society." At the third meeting he will demonstrate his "electronic turtle," one of the models he designed and built for the study of nerve mechanisms. The international seminars of the Postgraduate Center for Psychotherapy have been established under a grant by the Samuel Rubin Foundation. They will be presented semi-annually for the purpose of providing a platform in the United States for outstanding scientists from abroad who can present new ideas and approaches which may be integrated into the field of psychotherapy. The siminars will be presented with the assistance of an International Advisory Council. This program has been given formal sponsorship by the World Federation for Mental Health. The post-graduate center is a nonprofit organization dedicated to a four-fold program in mental health: to conduct clinics; provide out-patient psychotherapeutic services for some 700 children and adults who cannot afford private psychiatric fees; to serve as an advanced training center for psychotherapists; and to carry on intensive research programs in a continuing effort to develop better and shorter education programs.

Music Therapy Association.—The eighth annual conference of the National Association for Music Therapy, Inc., will be held Oct. 10-12 at the Kellogg Center for Continuing Education, Michigan State University, East Lansing. The agenda includes new music therapy techniques; relation between music therapy and special education; present status of music therapy in psychiatry; reports of current research; and music therapy as a developmental need for children. Registration fee is $6. Entertainment includes a concert by the Michigan State University Faculty Chamber Orchestra and a banquet Oct. 11. For information write the Kellogg Center for Continuing Education, Michigan State University, East Lansing, Mich.

Food and Nutrition Reprints.—The Council on Foods and Nutrition regrets that the cards requesting reprints from the Annual Meeting of the American Medical Association were lost in transit from New York and have not been located. Upon request, the Council will be glad to furnish a list of its available publications.

Hospital Association Meeting in Atlantic City.—The 59th annual conference of the American Hospital Association will be held Sept. 30-Oct. 3 in Atlantic City, N. J. Dr. Albert W. Snoke, president of the association and Mr. James D. Dyett, president of the Hospital Industries' Association, Buffalo, N. Y., will present addresses Sept. 30. A conference on hospital planning, "New Trends in Hospital Services," will be presented Sept. 30, with Dr. David B. Wilson as chairman.

Topics to be discussed in the general assembly are: education in the nation, an informed public, the nation's health. voluntary health care and government, and the future of hospitals. Technical exhibits are planned. A luncheon for international guests will be held Sept. 30. Round-table sessions will be conducted each afternoon. Entertainment includes the president's reception Sept. 30 and the banquet Oct. 2, at which the distinguished service award will be presented to Mr. John H. Hayes, hospital consultant, Douglaston. L. I., N. Y. For information write the American Hospital Association, 18 East Division St., Chicago 10, Ill.

Prevalence of Poliomyelitis.—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated:

Meeting on Psychosomatic Medicine.—The fourth annual meeting of the Academy of Psychosomatic Medicine will be held at the Morrison Hotel, Chicago, Oct. 17-19. Theme for the meeting will be "Psychosomatic Aspects of Obstetrics, Gynecology, and Endocrinology, Including Diseases of Metabolism." Foreign participants include Dr. Grantley Dick-Read, London, England; Dr. Bernard B. Raginsky, Quebec, Canada; and Dr. Carl W. R. Tupper, Nova Scotia, Canada. The program includes the following symposiums and moderators:

Psychosomatic Aspects of the Pre- and Postnatal Period, Dr. Edith P. Jackson, New Haven, Conn.

Psychosomatic Aspects of Pediatric Gynecology and Endocrinology, Dr. Goodrich C. Schauffler, Portland, Ore.

Psychologic Factors in Anesthesia, Dr. Raginsky.

Emotional Factors in Sterilization and Abortion (Spontaneous, Criminal, and Therapeutic), Dr. Flanders Dunbar, New York City.

Goals and Therapy in Psychosomatic Diseases, Dr. Dunbar.

A panel discussion, "Psychosomatic Infertility," moderated by Dr. M. Edward Davis, Chicago, will be held Oct. 18. Dr. Ethan Allan Brown, president of the academy, will present "Three Psyches, Two Somas" at the banquet Oct. 18. The fee is $10 for nonmembers. For information write Dr. William S. Kroger, Secretary, Academy of Psychosomatic Medicine, 104 S. Michigan Ave., Suite 415, Chicago 3, Ill.

Medical Meeting for Hunters.—The South Dakota State Medical Association is sponsoring a Hunter's Medical Meeting, Oct. 26-30, in Mitchell, S. D. The meeting is limited to 100 out-of-state doctors of medicine. Registration fee of $100 includes hunting license, hunting grounds, and guides, scientific sessions, and four dinners. If wives come with husbands and hunt, the registration fee is the same for each; if wives do not hunt, their registration fee is $75. A special motel has been reserved for out-of-state physicians. For information and registration blank, write Mr. John C. Foster, Executive Secretary, South Dakota State Medical Association, 300 First National Bank Building, Sioux Falls, S. D.

LATIN AMERICA

Medical School Teaching Program.—To continue the development of basic science teaching, the School of Medicine of the University of El Salvador, San Salvador, will supplement its staff and purchase further equipment for its departments of anatomy, biochemistry, microbiology, pathology, physiology, and preventive medicine. The Rockefeller Foundation has provided $171,000 for these purposes during the next year and a half. A teaching health center and out-patient facility adjoining the Medical School and its teaching hospital have been financed by the Ministry of Health, which is also providing the personnel needed to staff the center and to offer instruction in the fields of community health, nursing, and social services. Students receive basic training in such subjects as epidemiology and biostatistics in correlation with the associated basic sciences, and in their clinical years have practical training in public health and preventive medicine at the center and hospital. With support from the Salvadorian government, the Kellogg Foundation, the International Cooperation Administration, and private sources, the school has established a modern teaching center and has developed a trained group of academic personnel at both the basic and clinical science levels.

Three-Year Scholarship Grant.—The Pan American Medical Association announces a three-year medical scholarship to a Cuban physician to study internal medicine in the School of Medicine Wayne State University, Detroit. The recipient will be selected by a committee of five members of the Havana Chapter of the association, with Dr. Carlos F. Cardenas as chairman. The following stipulations are given: (1) the student-physician will be chosen on his record as a medical student and in his hospital internship of at least two years; (2) the candidate must speak English; (3) he must pledge to return to his country and practice medicine and to teach for at least ten years after completion of the scholarship. For information write Dr. Charles Pierre Mathé, Pan American Medical Association, 450 Sutter St., San Francisco 8, Cal.

Meeting of Pathologists in Mexico City.—The joint meeting of the American Society of Clinical Pathologists, Asociacion Mexicana de Patologos, and the College of American Pathologists will be held Oct. 7 at the Ciudad Universitaria. Addresses will be given by Dr. Raoul Fournier, dean, University of Mexico School of Medicine; Dr. Miguel Schulz, president, Asociacion Mexicana de Patologos; and Dr. Isaac Costero, honorary president, Sociadad Latino-Americana de Anatomo-Patologos. Responses will be given by Dr. W. A. D. Anderson, president, College of American Pathologists; Dr. John L. Goforth, president, American Society of Clinical Pathologists; and Dr. David A. Wood, president, American Cancer Society. The program includes the following presentations:

Cerebral Cysticercosis, by Drs. M. Schulz and F. Biagi, Pathology Unit, National University Medical School.

Amebiasis in Children, by Drs. M. Salas, K. Ambrosius and M. Esparza, Children's Hospital.

Cirrhosis of the Liver, by Dr. Ruy Perez Tomayo, Pathology Unit, National University Medical School.

Onchocercosis, by Dr. M. Martinez Baez, Tropical Diseases Institute.

Cerebral Lesions in Malaria, by Dr. I. Costero, National Heart Institute.

Tours of the campus of the university and of Mexico City are planned. For information write the College of American Pathologists, 2115 Prudential Plaza, Chicago 1, Ill.

FOREIGN

Congress on Wine and Alcohol.—The International Congress for Medicine will be held Oct. 11-13 at the Faculty of Medicine and Pharmacy, place de la Victoire, Bordeaux, France, under the presidency of Georges Portmann, honorary dean of the Faculty of Medicine and Pharmacy of Bordeaux. Problems to be considered are wine and health. The special reports will be accompanied by communications concerning the latest studies on the physiologic and microbicidal composition of various wines. Meetings will also take place in various viticultural regions of the district of the Gironde showing vineyards, vintage and the treatment of grapes. The organizing committee states that a large foreign participation is assured. Additional facultative trips to the southwest are planned. Entertainment includes a soiree at the Grand Theater of Bordeaux Oct. 11 and the official banquet in the castle of the Dukes of Epernon Oct. 12. For information write Secrétaire Général du Congrés, 36. Avenue d'Ares, Bordeaux, France.

CORRECTION

Dr. Walsh on President's Advisory Committee.—Through error, the name of Dr. William B. Walsh, internist, Washington, D. C., was not included in the listing of physician members of the Citizens' Advisory Committee to the President's Council on Youth Fitness, which was discussed in an editorial in The Journal, Sept. 7, page 54.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 17-19. Sec., Dr. D. G. Gill, State Office Building, Montgomery 4.

Arizona:* *Examination and Reciprocity.* Phoenix, Oct. 16-18. Exec. Sec., Mr. Robert Carpenter, 826 Security Bldg., Phoenix.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 7. Sec., Dr. Joe Verser, Harrisburg.

California: *Written Examination.* Sacramento, Oct. 21-24. *Oral Examination.* San Francisco, Nov. 16. *Oral and Clinical for Foreign Graduates.* San Francisco, Nov. 17. Sec., Dr. Louis E. Jones, 1020 N St., Sacramento 14.

Colorado:* *Reciprocity.* Denver, Oct. 8. *Examination.* Denver, Dec. 3-4. Exec. Sec., Mrs. Beulah H. Hudgens, 715 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 12-14. Sec., Dr. Creighton Barker, 160 St. Ronan St., New Haven. *Homeopathic. Examination.* Derby, Sept. 10. Sec., Dr. Donald A. Davis, Derby.

Delaware: *Examination.* Dover, Jan. 14-16. *Reciprocity.* Dover, Jan. 23. Dr. Joseph S. McDaniel, Professional Bldg., Dover.

District of Columbia:° *Reciprocity.* Washington, Sept. 9. *Examination.* Washington, Nov. 12-13. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington, D. C.

Florida:° *Examination.* Miami, Nov. 24-26. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Georgia: *Examination.* Atlanta, Oct. 8-9. *Reciprocity.* Atlanta, Oct. 10. Sec., Mr. Cecil L. Clifton, 111 State Capitol, Atlanta 3.

Idaho: *Examination and Reciprocity.* Boise, Jan. 13-15. Ex. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Iowa:° *Examination.* Des Moines, Dec. 2-4. Exec. Sec., Mr. Donald V. Saf, State Office Building, Des Moines 19.

Kentucky: *Examination.* Louisville, Dec. 9-11. Sec., Dr. Russell E. Teague, 620 South Third St., Louisville 2.

Maine: *Examination.* Portland, Nov. 12-14. *Reciprocity.* Portland, Nov. 12. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Reciprocity.* Baltimore, September. *Examination.* Baltimore, Dec. 10-13. Sec., Dr. Frank K. Morris, 1211 Cathedral St., Baltimore.

Massachusetts: *Examination.* Boston, Jan. 14-17. Sec., Dr. Robert C. Cochrane, 37 State House, Boston.

Michigan:° *Examination.* Lansing, Oct. 9-11. Exec. Sec., Dr. E. C. Swanson, 118 Stevens T. Mason Bldg., Lansing 8.

Minnesota:° *Examination and Reciprocity.* Minneapolis, Oct. 15-17. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: *Reciprocity.* Jackson, December. *Examination.* Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson 113.

Montana: *Examination and Reciprocity.* Helena, Oct. 1-2. Sec., Dr. Thomas L. Hawkins, 555 Fuller Ave., Helena.

Nebraska:° *Examination.* Omaha, June. Sec., Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Hampshire: *Examination and Reciprocity.* Concord, Sept. 11-13. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Jersey: *Examination.* Trenton, Oct. 15-18. Sec., Dr. Patrick H. Corrigan, 28 W. State St., Trenton.

New Mexico:° *Examination and Reciprocity.* Santa Fe, Nov. 18-19. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

New York: *Examination.* Albany, Buffalo, New York and Syracuse, Dec. 10-13. *Sec.*, Dr. Stiles D. Ezell, 23 South Pearl St., Albany 7.

North Carolina: *Endorsement.* Morehead City, Oct. 12. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination.* Grand Forks, Jan. 9-12. *Reciprocity.* Grand Forks, Jan. 12. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Endorsement.* Columbus, Oct. 1. *Examination.* Columbus, Dec. 17-19. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus 15.

Oklahoma: *Examination.* Oklahoma City, Dec. 14-15. Sec., Dr. E. L. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon:° *Reciprocity and Endorsement.* Portland, Oct. 3-5. *Examination.* Portland, January. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Rhode Island:° *Examination.* Providence, Oct. 3-4. Administrator of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, Dec. 10. Sec., Dr. H. E. Jarvey, Jr., 1329 Blanding St., Columbia.

South Dakota:° *Examination.* Sioux Falls, Jan. 21-22. Exec. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Tennessee:° *Examination.* Memphis, Sept. 25-26. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis 3.

Texas:° *Examination and Reciprocity.* Fort Worth, Dec. 5-7. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July 9-11. Director, Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Virginia: *Reciprocity.* Richmond, Dec. 4. *Examination.* Richmond, Dec. 5-7. Address: Office of the Secretary, 631 First St., S.W., Roanoke.

Washington:° *Examination.* Seattle, Jan. 13-15. Sec., Mr. Thomas A. Carter, Capitol Bldg., Olympia.

West Virginia: *Reciprocity.* Charleston, Oct. 7. *Examination.* Charleston, January. Sec., Dr. Newman H. Dyer, State Office Bldg., No. 3, Charleston 5.

Wisconsin:° *Reciprocity.* Madison, Oct. 18. *Examination.* Madison, January. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., Madison.

Wyoming: *Examination and Reciprocity.* Cheyenne, Sept. 30, Sec., Dr. Franklin D. Yoder, State Office Bldg., Cheyenne.

Alaska:° On application in Anchorage and Juneau. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: *Subject to Call.* Act. Sec., Dr. S. F. Provencher, Agana.

Hawaii: *Examination.* Honolulu, Jan. 13-14. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

Virgin Islands: *Examination.* St. Thomas, Nov. 13. Sec., Dr. Earle M. Rice, Charlotte Amalie, St. Thomas.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arizona: *Examination.* Tucson, Sept. 17. *Reciprocity,* Tucson, Sept. 19. Sec., Mr. Herman E. Bateman, University of Arizona, Tucson.

Arkansas: *Examination.* Little Rock, Oct. 7-8. Sec., Mr. S. C. Dellinger, Zoology Department, University of Arkansas, Fayetteville.

Connecticut: *Examination.* New Haven, Oct. 12. Exec. Asst., Mrs. Regina G. Brown, 258 Bradley St., New Haven 10.

District of Columbia: *Examination.* Washington, Oct. 21-22. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N. W., Washington, D. C.

Florida: *Examination.* Gainesville, Nov. 9. Sec., Mr. M. W. Emmel, Box 340, University of Florida, Gainesville.

Iowa: *Examination and Reciprocity.* Des Moines, Oct. 8. Sec., Dr. Elmer W. Hertel, Waverly.

Michigan: *Examination.* Ann Arbor and Detroit, Oct. 11-12. Sec., Mrs. Anne Baker, 116 Stevens T. Mason Bldg., West Michigan Ave., Lansing.

Minnesota: *Examination.* Minneapolis, Oct. 1-2. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis 14.

New Mexico: *Reciprocity.* Santa Fe, Sept. 29. *Examination.* Santa Fe, Oct. 20. Sec., Mrs. Marguerite Cantrell, Box 1522, Santa Fe.

Oklahoma: *Examination.* Oklahoma City, Sept. 27-28. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

South Dakota: *Examination.* Vermillion, Dec. 6-7. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Tennessee: *Examination.* Memphis, Sept. 25-26. Sec., Dr. O. W. Hyman, 62 South Dunlap St., Memphis 3.

Texas: *Examination.* Austin, October. Chief Clerk, Miss Pearl A. Barrera, 407 Perry-Brooks Bldg., Austin.

Wisconsin: *Examination.* Madison, Sept. 20 and Milwaukee, Dec. 7. Sec., Mr. William H. Barber, 621 Ransom St., Ripon.

°Basic Science Certificate required.

GOVERNMENT SERVICES

ARMY

Personal.—Dr. F. K. Mostofi has been appointed scientific director of the American Registry of Pathology of the Armed Forces Institute of Pathology, to succeed Dr. H. G. Grady, who resigned the post to become professor of pathology at the Seton Hall College of Medicine and Dentistry, Jersey City, N. J. Dr. Mostofi has been chief of the genitourinary section of the Armed Forces Institute of Pathology since August, 1948, a post which he will continue to hold in addition to his new appointment.

NAVY

Correspondence Course.—The correspondence course, Blood Transfusion, Methods and Procedures, NavPers 10998-1, a revision of the correspondence course, Special Clinical Services—Blood, NavPers 10998, is now available. Consisting of eight objective type assignments it is evaluated at 24 Naval Reserve promotion and nondisability retirement points. Since this is a minor revision of the former course, additional points will not be credited to Naval Reserve personnel who have previously completed the course, NavPers 10998. Applications for enrollment should be submitted on Form NavPers 992 (Rev. 2-56) and forwarded to the Commanding Officer, U. S. Naval Medical School, National Naval Medical Center, Bethesda, Md., via the applicant's respective command.

Personal.—Capt. Edward C. Kenney, commanding officer of the U. S. Naval Hospital, National Naval Medical Center, Bethesda, Md., has, since September, 1955, been elevated to the rank of rear admiral.

VETERANS ADMINISTRATION

Training in Occupational Therapy.—The Veterans Administration will accept an increasing number of students for training in occupational therapy, under the Physical Medicine and Rehabilitation Service, to help alleviate the national shortage in this field. The Veterans Administration has been training about 300 occupational therapy students at 17 hospitals each year. Admission of additional trainees to the hospital programs, on a "without compensation" basis, will enable the Veterans Administration to comply with recent requests from occupational therapy schools for affiliation with VA hospitals. These students will receive quarters and subsistence in return for their services, but they will not receive a stipend. Occupational therapy training in VA hospitals offers clinical experience in a variety of disease and disability categories.

Radioactive Counter.—A total body radioactivity counter has been designed and developed by Dr. Gerald J. Hine, a physicist in the radioisotope service of the VA Hospital in Boston. It is so sensitive that it can measure the tiny amounts of radioactivity naturally present in the human body. Physicians can study some functions inside the body by noting this radioactivity. The movements of radioactive tracers can be followed on the counter. Since the counter is extremely sensitive, only minute amounts of these tracers would have to be introduced into the body. This means that the patient can be studied longer with a smaller dose of an isotope than was possible before. The counter will be used to compare radioactive patterns in healthy people with those of patients with various diseases. Another advantage of the counter is that it can follow the actions of different radioactive isotopes involved in separate functions in the body simultaneously.

PUBLIC HEALTH SERVICE

Personal.—Dr. Otis L. Anderson, formerly chief of the Public Health Service Bureau of State Services, was assigned to the newly created post of assistant surgeon general for personnel and training. He was succeeded in the Bureau of State Services by Dr. David E. Price, formerly deputy chief of the Public Health Service Bureau of Medical Services. The changes become effective Oct. 1. The new position was established to provide as fully as possible for the development and utilization of Public Health Service Personnel.——Forrest J. Gerard, a member of the Blackfoot Indian tribe and former health association official in Montana and Wyoming, has been appointed Tribal Relations Officer of the U. S. Public Health Service Division of Indian Health, effective Sept. 3. In his new position, Mr. Gerard will be responsible for relations between some 250 Indian tribes and the federal government Indian health program.

DEPARTMENT OF COMMERCE

Radioisotope Techniques.—A radioisotope technique for determination of cardiac output which is said to offer virtually unlimited potential in the diagnosis and control of heart disease is described in a report (PB 121984 Blood Volume and Cardiac Output Determinations Using Radioisotopes, by R. E. Zipf, J. M. Webber, and G. R. Grove, Miami Valley Hospital, and T. F. McGuire, Wright Air Development Center. Nov., 1956. Price $1.00) of Air Force–sponsored research that is available through the Office of Technical Services, U. S. Department of Commerce, Washington 25, D. C. Simple and highly accurate, the technique can be used to demonstrate precisely the variations of cardiac output under stress and response to medications, and to measure the volume of whole blood, plasma, and erythrocytes.

DEATHS

Cohn, Alfred Einstein, member emeritus of the Rockefeller Institute in New York City, died at his home, Iron Hill Farm in New Milford, Conn., July 20, aged 78, of generalized arteriosclerosis and hypertension. Dr. Cohn was born in New York City April 16, 1879. He received his M.D. degree from Columbia University College of Physicians and Surgeons, New York City, 1904, and from 1907 to 1909 he studied in Germany, Austria, and England. While working in London with Sir James Mackenzie, he discovered the presystolic murmur. Later, working with Thomas Lewis, Dr. Cohn helped to set up the Einthoven string galvanometer for making electrocardiograms at University College in London. He returned to New York and practiced medicine for two years, serving as associate in pathology at Mount Sinai Hospital and an alumni fellow in pathology at Columbia. It was at Mount Sinai that he made his first electrocardiograms in the United States in 1910 and published a scientific paper on this work. In 1911 he joined the staff of the Rockefeller Institute, where he continued his research, bringing with him the galvanometer for making electrocardiograms; was associated with the Institute for 33 years, becoming a member in 1920, and retired in 1944. During World War I he served as a major in the Army Medical Reserve Corps with assignment to the Surgeon General's Office and also a lieutenant colonel in the American Expeditionary Forces as senior consultant on circulatory diseases. Between wars he served on the council of the Veterans Administration, holding his post until 1946. During World War II he was vice-president and later chairman of the executive committee of the Committee for National Morale, special advisor to the Board of Economic Warfare and a member of the Health Committee of the Office of Foreign Relief and Rehabilitation Operations. He was actively identified with many public health organizations in an executive capacity. Dr. Cohn served both as a member of the board of governors and chairman of the committee on research of the New York Heart Association for over 25 years and was on the board of governors of the New York Tuberculosis and Health Association. He was chairman of the scientific committee of the Research Council of Department of Hospitals of New York City and its treasurer from 1943 to 1951. He was a member of the advisory council of the Committee on Research in Medical Economics from 1936 to 1939, chairman of the Sub-committee on Heart Diseases and Rheumatic Fever for the 1939 New York World's Fair, and until his death, belonged to the Club for Research on Ageing. He served as a visiting professor in medicine at the Union Medical College in Peking, China, in 1925. He was on the executive committee, Group on Adult Education of the Carnegie Corporation and the Council of the American Association for Adult Education. From 1928 to 1940 he was a member of the Lasker Foundation and in 1930 was president of the Harvey Society. From 1930 to 1943 Dr. Cohn was a member of the committee on library of the New York Academy of Medicine and served as committee chairman from 1934 to 1941. He was on the board of governors of the Irvington House for the Care of Children with Heart Diseases and participated in planning its buildings. He served from 1933 to 1945 on the executive committee for Displaced Foreign Scholars and Displaced Foreign Physicians and from 1934 to 1945 was a member of the China Medical Board of the Rockefeller Foundation. Dr. Cohn also served as a director of the Student Service of America. From 1945 to 1947 he was a member and treasurer of the American Committee for Emigre Scholars, Writers and Artists. He was president of the School of Asiatic Studies for the Iranian Institute in New York from 1947 to 1949, having previously served on its board, was a resident member of the Council on Foreign Relations, a member of the board of the Sydenham Institution and a life member of the Metropolitan Museum of Art. Among the organizations to which Dr. Cohn belonged were: Association of American Physicians, American Society for Clinical Investigation, American Association of Anatomists, American Physiological Society, New York Academy of Sciences, American Association of the History of Medicine, and New York Academy of Medicine. He was an associate member of the American Medical Association. From 1924 to 1937 he was a member of the board of editors of *Journal of Clinical Investigation* and for eight years a member of the board of editors of the *Bulletin of the New York Academy of Medicine*. He was the author of four volumes: "Medicine, Science and Art: Studies in Interrelations," published in 1931; "Minerva's Progress," published in 1946; "No Retreat from Reason—and Other Essays," published in 1948; and "The Burden of Diseases in the United States," written with Claire Lingg and published in 1950. His alma mater honored him in 1940 by conferring the honorary doctor of science degree. Dr. Cohn's early investigations made fundamental contributions to the new technique of electrocardiography. It was through his endeavors that the classification of criteria of the diagnosis of various types of heart diseases was stimulated in this country.

♦ Indicates Member of the American Medical Association.

Lynch, Frederick James, Boston; born in Cambridge, Mass., Nov. 13, 1889; Harvard Medical School, Boston, 1919; specialist certified by the American Board of Obstetrics and Gynecology; member of the American Association of Obstetricians and Gynecologists of which he was at one time vice-president; past-president of the New England Obstetrical and Gynecological Society and the Boston Obstetrical Society; emeritus professor of obstetrics at Tufts College Medical School; at one time on the faculty of his alma mater; veteran of World War I; served on the staffs of the Cambridge City (Mass.) Hospital, Symmes Arlington Hospital, Arlington, Mass., Mount Auburn Hospital, Cambridge, Mass., Lawrence Memorial Hospital, Medford, Mass., Massachusetts General Hospital, Beth Israel Hospital, and the Boston City Hospital; died in the Phillips House, Massachusetts General Hospital, July 8, aged 67.

Bubis, Jacob Louis, Miami Beach, Fla.; born in Cleveland July 23, 1885; University of Wooster Medical Department, Cleveland, 1907; specialist certified by the American Board of Obstetrics and Gynecology; member of the Ohio State Medical Association, Cleveland Academy of Medicine, and the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; practiced in Cleveland, where he was for many years associated with the Mount Sinai Hospital, serving as chief of obstetrics and gynecology, and on the staffs of the Lakeside, St. Ann, and Maternity hospitals; formerly district surgeon for the Baltimore and Ohio Railroad; author of "Puerperal Gynecology" and "Women Are My Problem"; died in Mount Sinai Hospital July 23, aged 72, of hypertensive cardiovascular disease and cerebral hemorrhage.

Cavell, Roscoe William ⊕ Ann Arbor, Mich.; College of Medical Evangelists, Loma Linda and Los Angeles, 1921; assistant professor of psychiatry at the University of Michigan Medical School; member of the American Psychosomatic Society and the American Psychiatric Association; past-president of the Michigan Society of Neurology and Psychiatry; served as psychiatrist at the Wayne County General Hospital at Eloise, Mich.; for two years psychiatrist with the U. S. Public Health Service at the U. S. Penitentiary Annex in Fort Leavenworth, Kan.; veteran of World War II and formerly chief medical officer of the U. S. Induction Station in Detroit; psychiatric consultant to the Southern Michigan Prison; on the staff of the University Hospital; died July 13, aged 61.

Camero, Anthony Roland ⊕ Los Angeles; born in Philadelphia June 9, 1905; University of Pennsylvania School of Medicine, Philadelphia, 1929; certified by the National Board of Medical Examiners; specialist certified by the American Board of Pathology; member of the College of American Pathologists and the American Society of Clinical Pathologists; formerly on the faculty of his alma mater; practiced in Philadelphia, where he was associated with the Philadelphia General Hospital and Misericordia Hospital; consulting pathologist at St. Francis Hospital in Lynwood, Calif.; since 1940 director of laboratories, Queen of Angels Hospital, where he died July 20, aged 52, of periarteritis nodosum and coronary thrombosis.

Lewis, Joseph Davidson, Santa Barbara, Calif.; born in Newcastle, Pa., in 1871; Cleveland Medical College, Homeopathic, 1893; specialist certified by the American Board of Otolaryngology; life member of the American College of Surgeons; member of the American Academy of Ophthalmology and Otolaryngology; past-president of the Minnesota Academy of Ophthalmology; past-president of the Yuba, Sutter, and Colusa Counties Medical Society; from 1913 to 1922 chief of the department of otolaryngology, Minneapolis General Hospital; on the staffs of Santa Barbara Cottage Hospital, Santa Barbara General Hospital, and St. Francis Hospital; died May 31, aged 86, of cardiovascular accident and generalized arteriosclerosis.

Drennen, Earle ⊕ Birmingham, Ala.; born in Arkadelphia Oct. 13, 1882; Columbia University College of Physicians and Surgeons, New York City, 1906; served as professor of clinical surgery at the Medical College of Alabama; member of the founders group of the American Board of Surgery; member of the House of Delegates of the American Medical Association in 1915; member of the American Surgical Association, Southern Surgical Association, and the International Society of Surgeons; fellow of the American College of Surgeons; veteran of World War I, associated with the Highland Baptist, Children's, St. Vincent's, and University hospitals; died July 4, aged 74, of a heart attack.

Crow, Hubert Dinwiddie, Suffolk, Va.; born in Raleigh, N. C., Dec. 4, 1911; Medical College of Virginia, Richmond, 1938; interned at the Medical College of Virginia, Hospital Division, Richmond; member of the Medical Society of Virginia; health director of a combined district health unit comprising the counties of Southampton, Isle of Wight, Nansemond, and the city of Suffolk; served as director of the medical training section of the state health department; on the staff of the Louise Obici Memorial Hospital; died July 21, aged 45, of a heart attack.

Ely, Donald, Portsmouth, N. H.; University of Pennsylvania School of Medicine, Philadelphia, 1954; certified by the National Board of Medical Examiners; interned at the Abington (Pa.) Memorial Hospital; served a residency in psychiatry at the Pennsylvania Hospital, Department for Mental and

Nervous Diseases in Philadelphia; service member of the American Medical Association; lieutenant in the U. S. Naval Reserve stationed at the Retraining Command in Portsmouth; died in Exeter (N. H.) Hospital June 24, aged 28.
